The [Austrian] Anschluss by the Third Reich was very positively received by the Treibacher management, because they hoped for an improvement of the economic situation. In 1939 the TCW became a member of the St. Joachimsthaler Bergbaugesellschaft m. b. H. and thus obtained most of the raw materials from St. Joachimsthal (Bohemia). The Carinthian company also received uranium pitch blends from this important ore deposit and in 1940 a separate uranium division was set up within the radium department. One of JOBERG's partners was the Auergesellschaft in Berlin, which was closely linked to the German atomic bomb project in the Second World War. During the war, the Berlin company had its ore concentrates from St. Joachimsthal reworked in Treibach. Therefore, TCW's relations to the nuclear energy project, albeit via third parties, are very probable. There are several indications, but absolute evidence is no longer to be found. It is certainly important to note that from the beginning of the forties radioactive substances were only allowed to be used for armament purposes. From 1942 onwards, radium was only used for the production of fluorescent paints within the armaments industry.

In May 1945 Carinthia was occupied by British troops. The Treibacher Werke were classified as German property, as a considerable share was owned by a German company. All of the mesothorium and radiothorium was confiscated by the British and later compensated. Due to the resulting shortage of raw materials, the radium and uranium division was shut down in 1946.

[Treibacher Chemical Works in Austria had very similar uranium- and thorium-processing capabilities to Auergesellschaft in Germany, yet historically it has been much less well known and much less studied. How much work could Treibacher Chemical Works have done for a nuclear weapons program during the war? From how many different sources did Treibacher receive uranium and thorium ore? How much uranium and thorium did Treibacher process during the war? Where did Treibacher send the uranium and thorium that it processed?]

Report on Treibacher Chemical Works AG. 10 October 1945. [CIOS ER 343, AFHRA A1008 frames 0794–0797]

[...]

Firm representatives seen:

Dr. Harmann Auer von Welsbach
Dr. Techn. Fritz Gemillscheg
Dr. Karl Buche
Dr. Haas (?) (in charge of radium plant)

1. This firm was founded in its present form by the great chemist Auer von Welsbach who invented the Thorium oxide gas mantle, “Mischmetall” lighter flint metal and did a great deal of research work on “Rare Earth” group of elements.

This is a firm of first class importance as it is one of the very few firms in the world which produces radium.

2. Principal Products.

(a) Radium Salts

Before the war this firm produced on an average of 8 or 9 grammes of Radium (as Radium Bromide) per year. This is a very large output. The radium was produced mostly on British orders from Pitchblende ore imported from the Congo. During the war they used Pitchblende from Joachimstahl in Czechoslovakia (where it was first discovered) and from Erzgebirge. These sources of supply are now closed, and the firm has not pitchblende in stock. [...]

(b) Mesothorium Salts

This element is even more powerfully radioactive and more dangerous to handle than Radium. It is produced in small quantities.

(c) Uranium Salts

These are used chiefly in the ceramic industry. They are produced as a by-product of the production of Radium from Pitchblende (Pitchblende is really principally an Uranium ore.) [...]

Finally

It is considered that this firm is of first-class importance, with a very highly trained expert staff of chemists and chemical engineers and workpeople. Their most important product being radium and Mesothorium salts, with Uranium salts, lighter flint metal, salts of the “Rare Earth” metals, and Ferro alloys, as their less vitally important products.

REPORT ON TREIBACHER CHEMICAL WORKS A.G.
(Treibach Works)
Target No. C-22/1325

MANUFACTURE OF RADIUM SALTS, URANIUM SALTS, AND FERRO ALLOYS

Firm representatives seen:

Dr. Harmann Auer von Welsbach
Dr. Techn. Fritz Gemillscheg
Dr. Karl Buche
Dr. Haas (?) (in charge of radium plant)

1. This firm was founded in its present form by the great chemist Auer von Welsbach who invented the Thorium oxide gas mantle, "Mischmetall" lighter flint metl and did a great deal of research work on "Rare Earth" group of elements.

This is a firm of first class importance as it is one of the very few firms in the world which produces radium.

2. Principal Products.

(a) Radium Salts

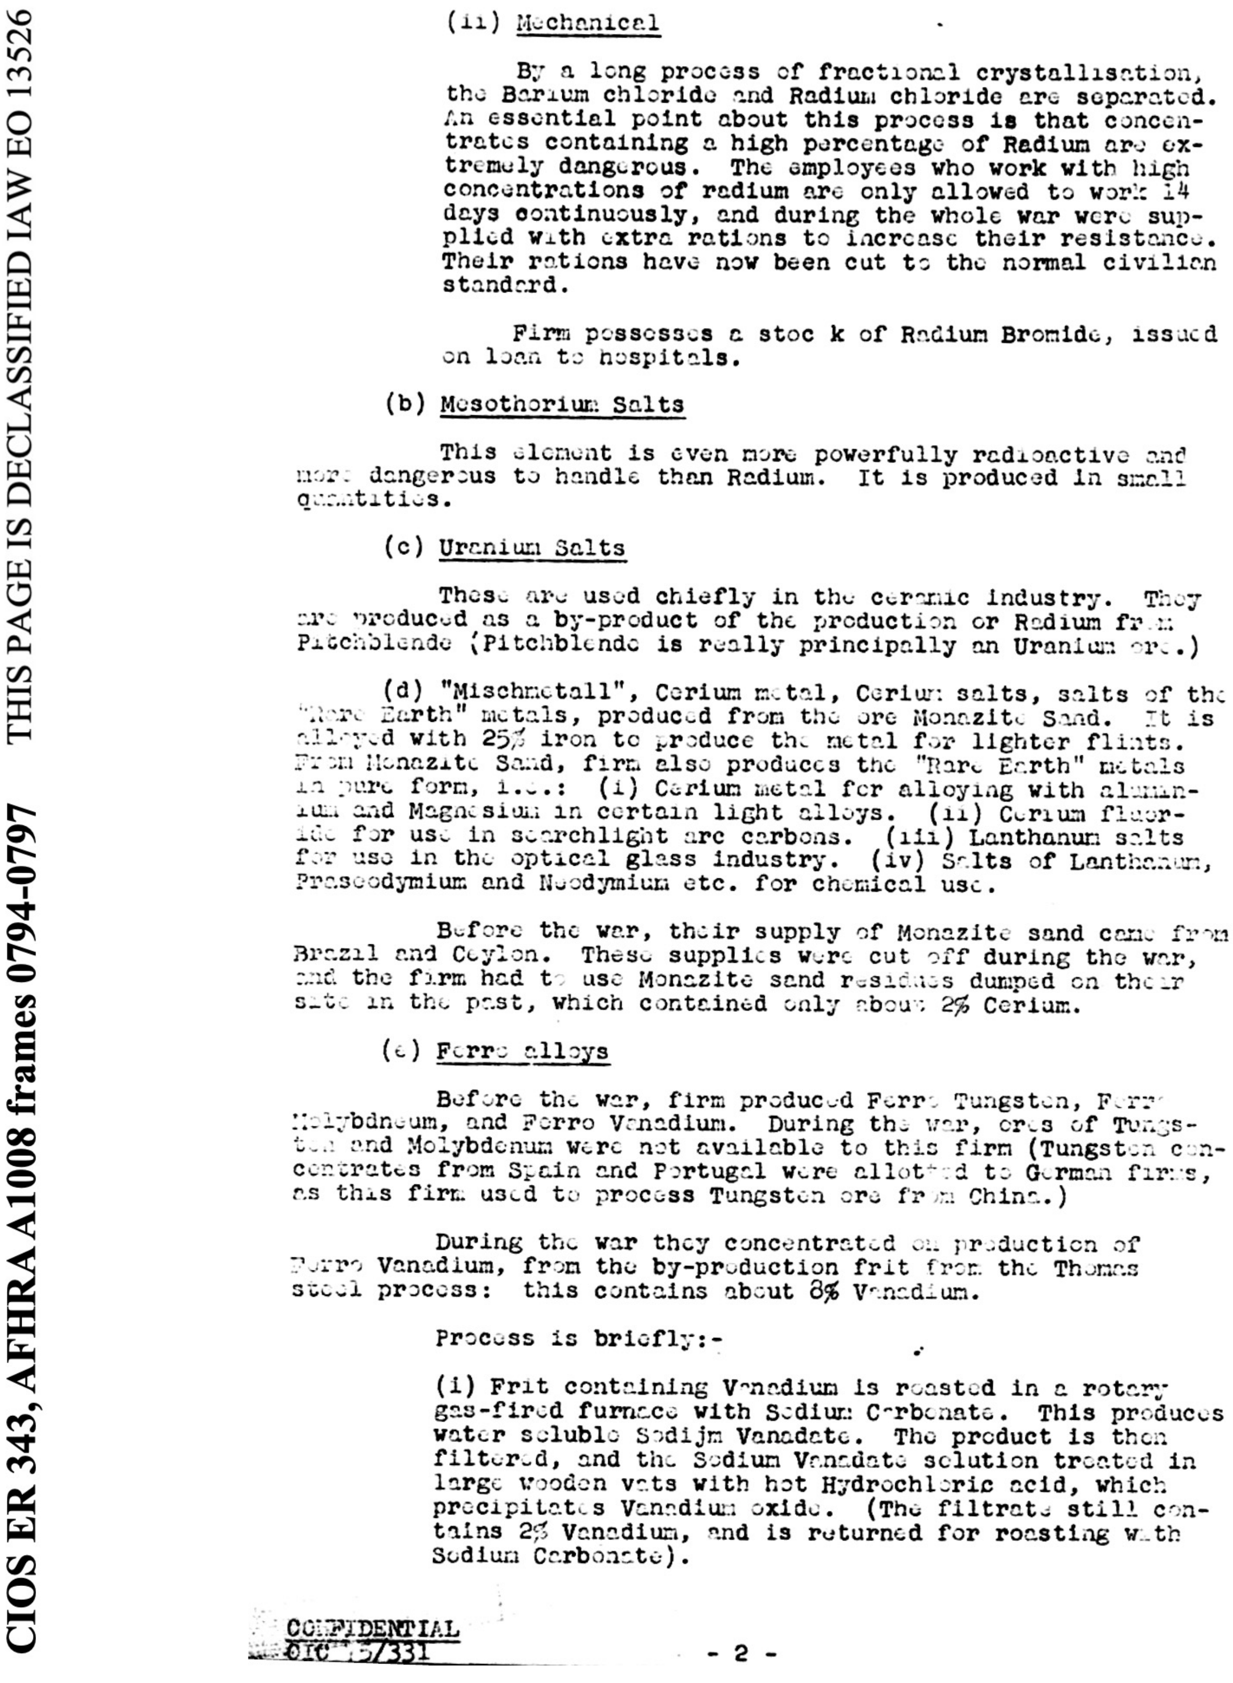
Before the war this firm produced on an average of 8 or 9 grammes of Radium (as Radium Bromide) per year. This is a very large output. The radium was produced mostly on British orders from Pitchblende ore imported from the Congo. During the war they used Pitchblende from Joachimstahl in Czechoslovakia (where it was first discovered) and from Erzgebirge. These sources of supply are now closed, and the firm has not pitchblende in stock. They are still working, but are doing the final processing of previous supplies, as the production of pure Radium Bromide is a slow process. The firm is interested in the possibility of obtaining pitchblende ore from U.S.A. or Canada.

The production process is very briefly:

(i) Chemical

The pitchblende (containing mostly Uranium oxide with a very small percentage of Radium) is digested with concentrated Sulphuric acid, then filtered. The Uranium salts (by-product) is thus separated from the mixed Barium and Radium Sulphate, which remains in solution. The mixed Barium and Radium Sulphate is then converted into Chloride by action with Hydrochloric acid.

Figure D.95: Report on Treibacher Chemical Works AG. 10 October 1945 [CIOS ER 343, AFHRA A1008 frames 0794–0797].



CIOS ER 343, AFHRA A1008 frames 0794-0797 THIS PAGE IS DECLASSIFIED IAW EO 13526

(ii) Mechanical

By a long process of fractional crystallisation, the Barium chloride and Radium chloride are separated. An essential point about this process is that concentrates containing a high percentage of Radium are extremely dangerous. The employees who work with high concentrations of radium are only allowed to work 14 days continuously, and during the whole war were supplied with extra rations to increase their resistance. Their rations have now been cut to the normal civilian standard.

Firm possesses a stoc k of Radium Bromide, issued on loan to hospitals.

(b) Mesothorium Salts

This element is even more powerfully radioactive and more dangerous to handle than Radium. It is produced in small quantities.

(c) Uranium Salts

These are used chiefly in the ceramic industry. They are produced as a by-product of the production or Radium from Pitchblende (Pitchblende is really principally an Uranium ore.)

(d) "Mischmetall", Cerium metal, Cerium salts, salts of the "Rare Earth" metals, produced from the ore Monazite Sand. It is alloyed with 25% iron to produce the metal for lighter flints. From Monazite Sand, firm also produces the "Rare Earth" metals in pure form, i.e.: (i) Cerium metal for alloying with aluminium and Magnesium in certain light alloys. (ii) Cerium fluoride for use in searchlight arc carbons. (iii) Lanthanum salts for use in the optical glass industry. (iv) Salts of Lanthanum, Praseodymium and Neodymium etc. for chemical use.

Before the war, their supply of Monazite sand came from Brazil and Ceylon. These supplies were cut off during the war, and the firm had to use Monazite sand residues dumped on their site in the past, which contained only about 2% Cerium.

(e) Ferro alloys

Before the war, firm produced Ferro Tungsten, Ferro Molybdneum, and Ferro Vanadium. During the war, ores of Tungsten and Molybdenum were not available to this firm (Tungsten concentrates from Spain and Portugal were allotted to German firms, as this firm used to process Tungsten ore from China.)

During the war they concentrated on production of Ferro Vanadium, from the by-production frit from the Thomas steel process: this contains about 8% Vanadium.

Process is briefly:-

(i) Frit containing Vanadium is roasted in a rotary gas-fired furnace with Sodium Carbonate. This produces water soluble Sodijm Vanadate. The product is then filtered, and the Sodium Vanadate solution treated in large wooden vats with hot Hydrochloric acid, which precipitates Vanadium oxide. (The filtrate still contains 2% Vanadium, and is returned for roasting with Sodium Carbonate).

CONFIDENTIAL

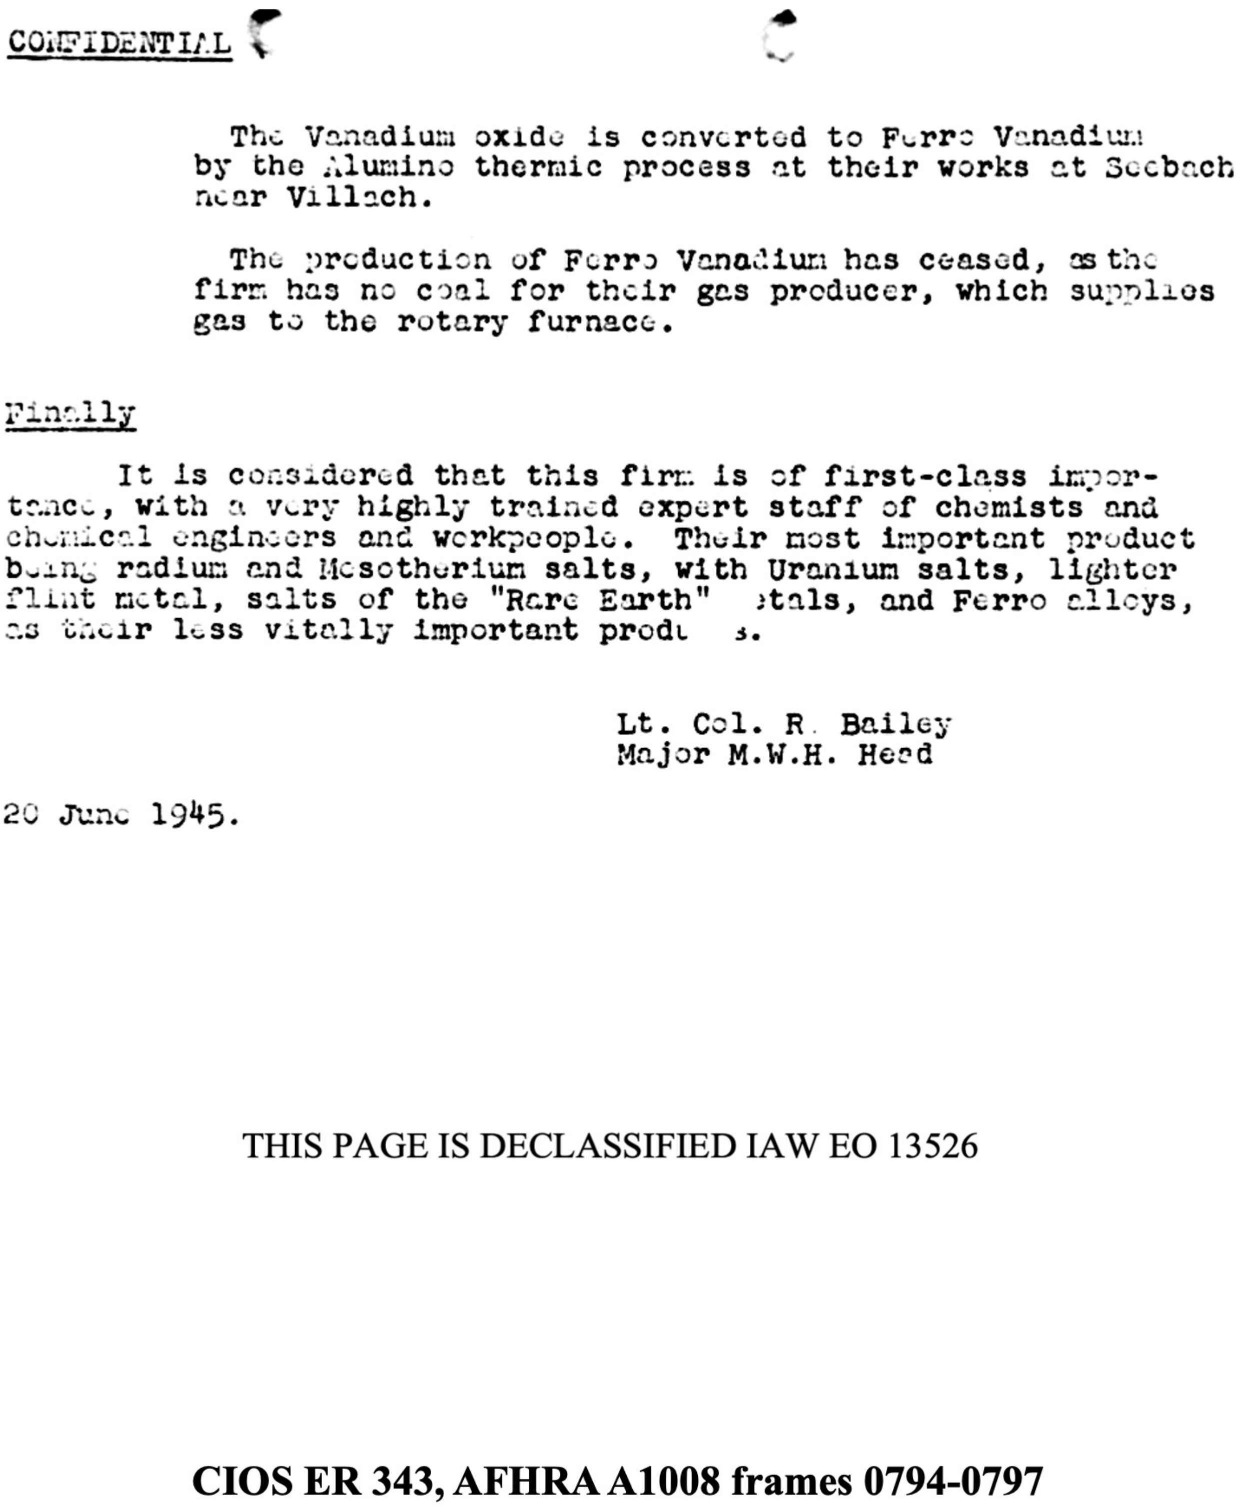
- 2 -

Figure D.96: Report on Treibacher Chemical Works AG. 10 October 1945 [CIOS ER 343, AFHRA A1008 frames 0794–0797].



CONFIDENTIAL

The Vanadium oxide is converted to Ferro Vanadium by the Alumino thermic process at their works at Seebach near Villach.

The production of Ferro Vanadium has ceased, as the firm has no coal for their gas producer, which supplies gas to the rotary furnace.

Finally

It is considered that this firm is of first-class importance, with a very highly trained expert staff of chemists and chemical engineers and workpeople. Their most important product being radium and Mesotherium salts, with Uranium salts, lighter flint metal, salts of the "Rare Earth" metals, and Ferro alloys, as their less vitally important products.

Office Memorandum • UNITED STATES GOVERNMENT

TO : File DATE: 3 September 1946

FROM : H.S. Lowenhaupt

SUBJECT: Removal of uranium, Treibach Chemische Werke, Austria.

Correspondence, Eaton to Jannarone, 28 Aug. 1946 indicates that 8 tons of uranium salts at the Treibach Chemische Werke in the British Zone of Austria is to be removed by the British to the USA. The uranium was derived from Joachimsthal concentrates imported before the end of the war from Joachimsthal.

Treibach Chemische Werke Aug.1946
Austria

I. Uranium Salts

It was desired to determine the exact quantity of uranium salts now held by Treibach and also whether it would be possible to remove the stock to the U.K.

Previous negotiations and queries had gone through Lt.Col.Boyd of the Mil. Gov. at Klagenfurt. It was found out however that he is now stationed in Vienna, with the Trade and Supply Branch of the Economics Division, A.C.A. He was contacted and also Col.Daw, Industry Branch, and Mr.G.G.Finch, Chemical Section. The latter holds up to date records of the firm's activities, in which it is stated that the present stock is 8.00 tons of uranium salts, mainly in bulk form, unpacked. The difference between 8.0 tons and the 8.2. tons mentioned in previous documents is thought to be due to a small quantity sent to a ceramics firm, possible in Italy.

On the question of removal, it was stated that throughout the firm had been most helpful and co-operative. Their raising of the question of payment for the mesothorium is said to be only normal business instincts. They are unlikely to raise the matter other than with the British element, especially if they can be given a firm assurance or concrete evidence, such as a credit payment to the Austrian National Bank, that H.M.G. intends to pay for the mesothorium. The authorities here consider that such concrete action before raising the matter of the purchase and removal of the uranium salts would ensure the success of that transaction.

With regard to the mechanics of the removal, it is thought that either wooden kegs to hold about 250 Kg. each or oil drums or carbide drums could be obtained. Two reasonable methods of transport are possible:- C/r

(a) by train to Villach, Karlsruhe, etc. to Calais. A special truck and additional train guards could probably be obtained. This journey takes about 3½ days. 10.70

(b) by air from Klagenfurt. Owing to the state of the air strip in uncertain weather, September is the best month to carry out the air lift. Dakotas can land on this airfield. Alternative air transport would be from Vienna which would entail road transport of the material through the Russian zone. (Egypt)

It was tentatively arranged, that if, and when the decision to remove the material is taken, Mr.Finch would endeavour to obtain suitable containers, get the material packed and then inform us of the gross weight and number of packages. It was suggested that this should be known as Operation Spray.

Communications on the subject should be sent to Director, Economics Division, A.C.A.(B.E.), C.M.F.

II. Czechoslovak Claim

It is considered in Vienna that the Czech claim for 9223 Kg. uranium ore from Treibach was probably Russian inspired, and that the matter has now been dropped

C/r Egypt

III. Monazite Sands

Treibach now want to restart manufacture of flints for which they require monazite sands, which they propose to get from the mouth of the Nile in Egypt. It is probable that /this

sand contains very little thorium. Econ. Div. would like to know whether there is any objection to the supply of monazite from that source. Treibach also used to obtain such sands from Africa(?) and Brazil.

Figure D.98: H. S. Lowenhaupt. 3 September 1946. SUBJECT: Removal of uranium, Treibach Chemische Werke, Austria [NARA RG 77, Entry UD-22A, Box 174, Folder 10.70 Austria Misc].

III. Employees.
IV. Production Program.
V. Sales and Markets.
VI. Russian Deliveries.

- - - - - - -

I. History.

The Gruenau firm was founded in 1880 (approximately) for the manufacture of intermediate products for the paint industry (e.g. naphtol for the Hoechst paint factory) by the chemist Landsdorff and Meyer.

After World War I a merger of the firm with the Balzer chemical factory took place, the production of pharmaceuticals, textile by-products, and construction by-products was started. A clash with the "Degussa" (German gold and silver separation plant, belonging to the I.G. Farben combine) occurred when the firm made use of chemist Dr. Arndt's patents on treatment of metal surfaces. Due to financial difficulties of the Gruenau chemical factory during the inflation, one-third of the Meyer family's stock ownership went into the hands of "Degussa". The Meyers left Germany after 1933 and "Degussa" obtained the balance of their Gruenau stocks.

Production was increased during World War II and the manufacture of uranium metal from pitchblende was started on a large scale. At that time the factory employed over 1,000 workers. About 60 per cent of the factory was damaged by air attacks in spring 1945, and the surface treatment department and all the uranium installations, as well as the company's own power

plant, were fully dismantled after the Red Army occupied Berlin.

Sequestration of what was left of the factory was carried through in 1946 by the district office - Bezirksamt - (property of combines);

Figure D.100: CIA Information Report: The Chemische Fabrik Grünau. 29 November 1949 [https://www.cia.gov/readingroom/document/cia-rdp83-00415r003900020006-0]. “Production was increased during World War II and the manufacture of uranium metal from pitchblende was started on a large scale. VISIT TO RADIUM CHEMIE COMPANY, FRANKFURT.

25 Apr '45

TARGET TEAM.	Col. Sir Charles Hambro.	British Army.
	Major R. Furman, C.E.	U.S. Army.
	Major D.C.G. Gattiker.	British Army.

OBJECTIVE.

This target was visited on 25th April 1945 in order to determine what use had been made of 11 tons of crude sodium uranate delivered to the firm in July 1943 from Wirtschaftliches Forschungsgesellschaft.

LOCATION OF TARGET.

It was discovered that the original premises of the firm in Frankfurt had been destroyed in about 1943. A new laboratory had subsequently been built on the original site but this had again been destroyed towards the end of 1944. It was learnt that Dr.Gorup, the Director of the firm, had been called up some months ago and the party therefore went to the house of the Deputy Director, Dr. Giebenfein in Dorningheim, near Harau about 15 miles east of Frankfurt.

BUSINESS OF FIRM.

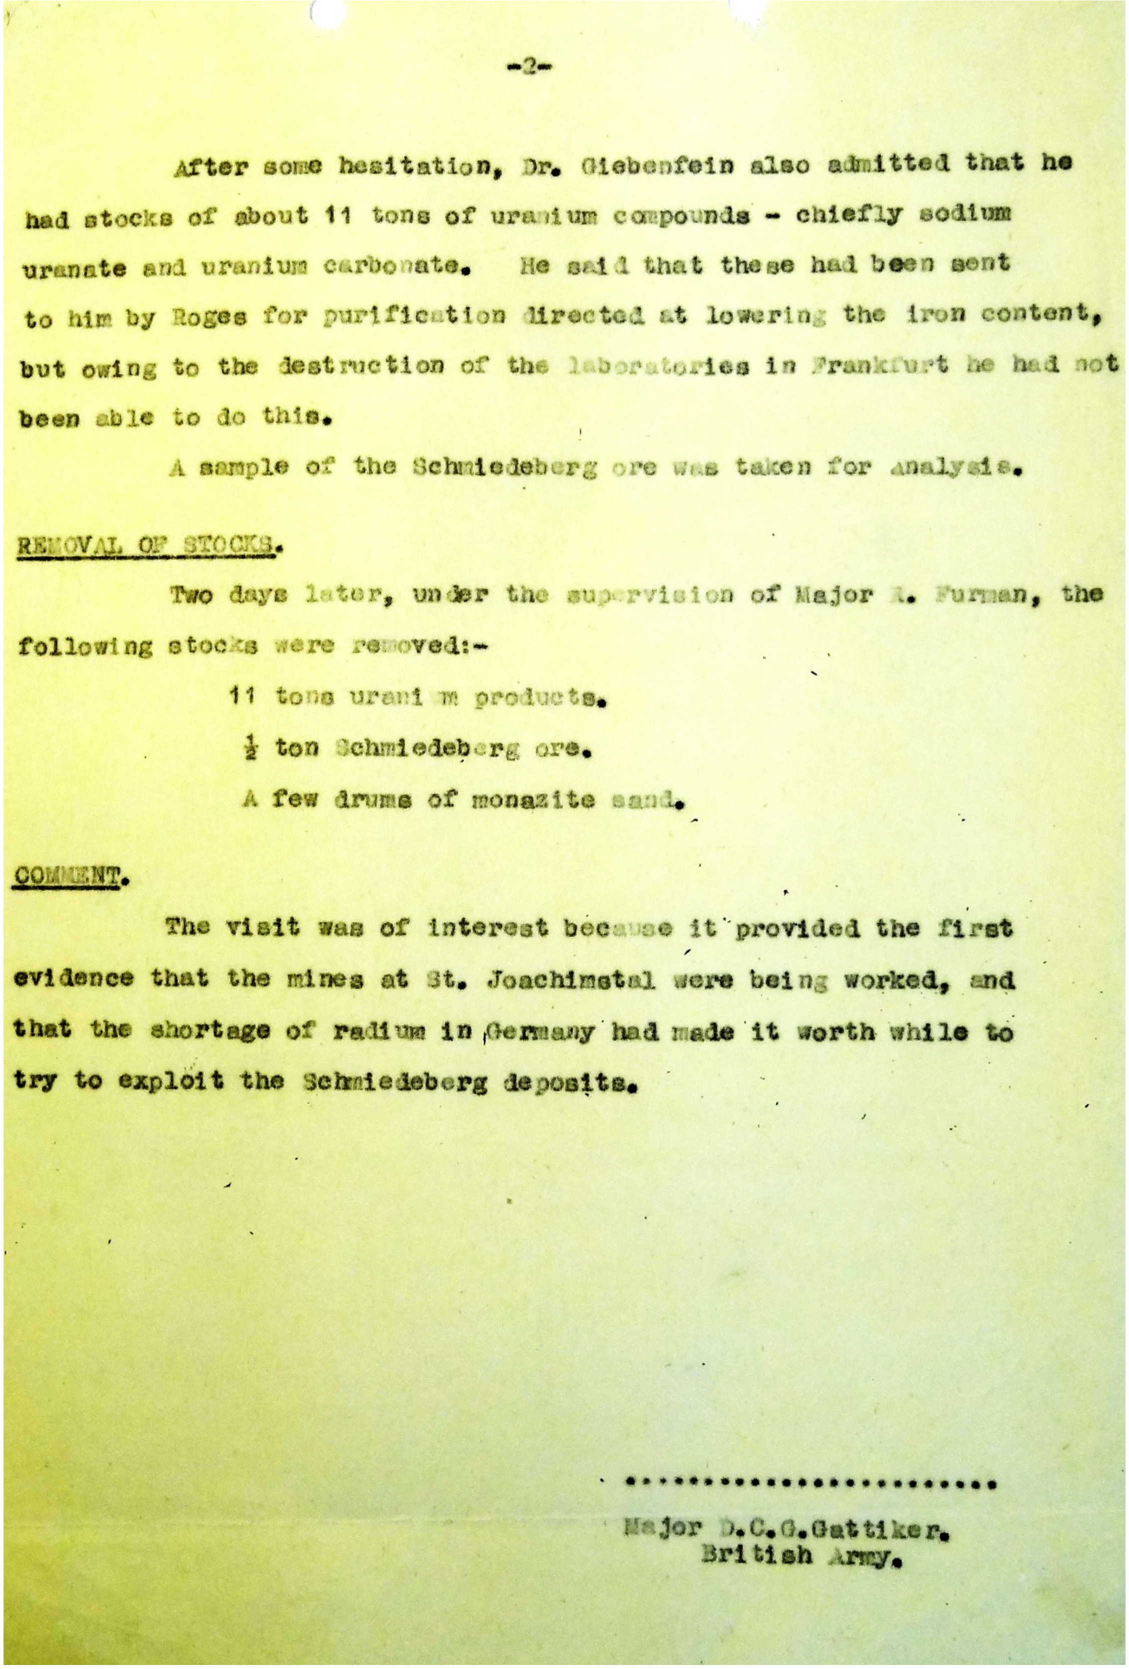
Interrogation of Director. It was clear both from the ruins of the laboratory in Frankfurt and from the laboratory in Dr. Giebenfein's house where the business of the firm was being continued on a restricted scale, that the firm was chiefly concerned with the extraction and refining of radium and mesothorium, and the preparation therefrom of luminous compounds. Questioned as to the origin of the ores from which radium was extracted, Dr. Giebenfein stated that in about 1942 he had received a ton of ore from St. Joachimstal and more recently about ½ a ton of ore from Schmiedeberg in the Rissengebirge. He did not know the extent of the mining operations at either of these localities, but he knew that the three partners of the Radium Syndicate - Auer gesellschaft, Buchler & Co., at Brunswick, and Goldschmidt at Treibach, in Austria, were engaged on extraction and refining of radium. He did not know the origin the monazite ore supplied to him.

dup cy dest

e luminous compounds were supplied to the Luftwaffe.

Figure D.101: David C. G. Gattiker. 25 April 1945. Visit to Radium Chemie Company, Frankfurt [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

DECLASSIFIED
Authority NND 917017



-2-

After some hesitation, Dr. Giebenfein also admitted that he had stocks of about 11 tons of uranium compounds - chiefly sodium uranate and uranium carbonate. He said that these had been sent to him by Roges for purification directed at lowering the iron content, but owing to the destruction of the laboratories in Frankfurt he had not been able to do this.

A sample of the Schmiedeberg ore was taken for analysis.

REMOVAL OF STOCKS.

Two days later, under the supervision of Major A. Furman, the following stocks were removed:-

11 tons uranium products.
½ ton Schmiedeberg ore.
A few drums of monazite sand.

COMMENT.

The visit was of interest because it provided the first evidence that the mines at St. Joachimstal were being worked, and that the shortage of radium in Germany had made it worth while to try to exploit the Schmiedeberg deposits.

....

Cable from Perrin for Hambro

1. Contrary to expectations it appears that Wismar is in British hands. The stock of 80 tons of sodium salt held by Hoffman and Molzen there is the largest single quantity remaining in Germany.

2. In view of this and despite agreement not to collect more material would be grateful if you could discuss with Groves and let us know whether attempt should be made to get material away or destroy it by, for instance, dumping in river, or whether no action should be taken.

Nr: 43679 8 May 1945

To MILID sr nr 43679 ICCO personal to Groves and Hambro from Welsh and Perrin TOP SECRET from Van Voorst.

Urgent message received from Calvert and Gattiker. They report 81 tons sodium salt were transferred from Wismar to Neustadt Glewe where there is also 60 tons oxide from Berlin. Neustadt Glewe is three miles beyond our zone.

Gattiker and Calvert request immediate instructions on choice of following action.

1. Leave alone.
2. Attempt to recover material.
3. Attempt to sabotage and start fire as cover.

→ Possibility (2) might be tried on excuse of recovery stolen material or by bluff.

Decision must be taken immediately and we see no chance of getting Chancellors opinion.

Uranium Salts at Ludwigslust Used by Factory.

1. The stock of uranium salts stored at the Nord-Deutsches Lederwerk in Neustadt-Glewe near Ludwigslust has been almost entirely consumed by the factory, with the waste material flowing into the Elde River.

2. About a bagful of the material is said to remain. The stock had been kept in a loose condition in two storerooms.

Field Comment: This confirms previous information, forwarded to General Sibert on 24 April, which stated that no part of the material, whose true nature appeared to be unknown to both the Russians and the factory owner, had been removed; and that most of it had been consumed in the production of white glove leather and some horse harnesses.

Ludwigslust Uranium Salts Stock Consumed.

The information below amplifies and supplements that contained in a report of 4 May 1946, and other earlier reports from the same source:

1. Confirmation has been made of earlier information that: ?

a. The stock of uranium salts (cadmium iodine, Cd I2) at the Nord - Deutsches Lederwerk in Neustadt-Glewe near Ludwigslust has been consumed, except for an infinitesimal balance.

b. Neither the factory employees nor the Russians knew the nature of the material and the latter did not requisition or remove any of the salt, which was used as tanning salt in the process of alum-tanning to produce chamois leather.

c. The resulting waste material went into the Elde River without any noticeable chemical reaction.

d. The salt was stored loosely in a cellar-like vault.

2. Only one type of salt was on hand; its origin and the method by which it was obtained were unknown. Dr. Elflein, the former manager of the factory and an ex-SS man, may have had this information. Nothing is known of him since his arrest by the Russians approvimately six months ago, but it appears that Elflein did not tell the Russians anything about the salt stock.

3. One remaining question is whether sample No. 2 of the salt, procured earlier, is identical with sample No. 1. Some dirt may have been mixed in with sample No. 2.

2 July 1946

SUBJECT: Material at Newstadt-Glewe.

TO: Lt. Colonel E. P. Dean, Office of the Military Attache, American Embassy, London, England.

1. In the last few weeks we have received several confirmative reports on the situation at Newstadt-Glewe as summarized in our Weekly Intelligense Summary No. 12.

2. All reaction to these reports is: Very nice, if true; however, the thing sounds to fantastic to be true. For example:

(a) Some of the material is known to have been shipped to Newstadt-Glewe in wooden casks. It is doubtful that it would be handled in sacks or bags, or that it would be stored loosely in the cellar, because of its weight and value.

(b) Why should such valuable material be used for tanning? So far as we can determine it has never been so used before. Possibly Elflein (or Elfrich) or his successor might have wanted to cover-up, to protect himself from the Russians or to keep them from getting the material.

(c) If use of this material was suddenly instituted, would it not be noted and noised about by factory employees? Would it not also result in a change in the properties of the leather?

(d) The information has come too easily, from too many different sources.

3. We would rather believe that the material was buried, or has or is being transferred elsewhere in the Russian zone or into the low countries.

4. Rather than accept the current story, we have asked for additional investigation, to determine if the information given is true, or whether it is designed to mislead.

5. Gattiker has also asked Welsh to redirect his attention toward Newstadt-Glewe.

SCIENTIFIC

NORDDEUTSCHE LEDERWERKE IN NEUSTADT

1. The double sentries on the Norddeutsche Lederwerke are no longer there. In the factory itself there are only a few Russian soldiers who operate snap controls among the workers to prevent the smuggling of leather out of the factory.

2. The uranium oxyde is still in the factory and is not specially guarded. In the opinion of the cashier HINRICH there may be from fifty to seventy tons. HINRICH thinks it is for use in tanning (GERBSTOFF). The present application of the material is not known, but the Russians appear to have no interest in it whatever and it is not thought that any has been or is being used or taken away.

3. Anyone working in the factory could enter the shed in which the salts lie. Source was himself offered work in the factory but could not accept as he had no local identity papers.

4. Some four weeks ago fifty per cent of the machines of the Lederwerke were loaded and shipped away. These machines stood on the railway station exposed to the weather since last year.

H. S. LOWENHAUPT.

Memorandum • UNITED STATES GOVERNMENT

SECRET

:Major F.J. Smith DATE: 1 October 1945

..OM :H.S. Lowenhaupt

SUBJECT: OCE Report "German supplies of uranium-bearing raw materials":

1. War production at Joachimsthal was 15 to 25 tons of U_3O_8 per year. This was the only war source of new ore.

2. An unidentified mine in Portugal was bought by the Germans but resulted in no significent production.

3. There is reported some 700 tons of proved ore bearing 2% or 14 tons of U_3O_8. Attempted production by the Germans apparently failed.

4. Small veins carrying silver and uranium minerals occur in association with iron deposits at Schmiedberg. They yielded 9 tons between 1927 and 1930.

5. Pitchblende has been produced in small amounts from lead silver veins at Freiberg.

6. Pitchblende has been produced in small amounts from nickel cobalt ores at Schneeberg.

7. There has been practically no production from French continental sources.

8. Our files carry considerable more detail on each of these points.

Henry S. Lowenhaupt

28 February 1946

MEMORANDUM for the period 17 January 1946 to 28 February 1946.

From: Washington Office of Joint TA Intelligence Section.

To: London Office.

RUSSIA

1. Ore Deposits: Alleged Russian activity in Czechoslovakia, Bulgaria, China, Manchuria, and elsewhere, tends to indicate that Russia has not yet discovered, or alternatively, not developed, any source of uranium within her own territory comparable to the deposits in Canada or the Congo. Neither Dr. Bain nor Dr. Davidson considers, on geological grounds, that a previous report concerning rich deposits in the Kolyma River Valley is likely to be true.

There is no doubt, however, that extensive geological surveying of Russian territory has been and is taking place and although there is nothing to suggest that such surveys are specifically directed towards finding radioactive minerals, it must be borne in mind that the possibility of rich deposits being found in the near future, either by design or by accident, cannot be excluded.

According to 'Foreign Commerce Weekly' (2.2.46) a discovery has been announced at Jabagai, in the Kazakhstan District, of large deposits of vanadium ore containing a high content of radioactive substances. So far we have not been able to locate this place on the map.

Reference is also made to these deposits in an article entitled "Metals of Kazakhstan" by N. Undasynov, which appeared in the 'Mining Journal', London, 24.11.45. This article states that there are millions of tons of excellent ore. We should be glad to have any information on this deposit and its exact location, which London can obtain.

2. Material Reserves: Assuming that no new rich deposits are discovered within the territory under their control, it is unlikely that Russia will be able to obtain more than the equivalent of 300 to 500 tons of oxide within the next five years. This takes into account known amounts of captured German stocks and assumes that methods will not be developed within that time for extracting uranium from very low-grade extensive deposits such as oil shales and asphalts.

3. Scientific Effort: Available evidence, although admittedly very slender, indicates that Russia is intent on devoting as much scientific effort as possible to mastering the uranium problem. It is of interest to note, however, perhaps, that emphasis appears to be directed towards Isotope separation and as yet there has been no reference to Plutonium production. Reference to interest in obtaining uranium with a 235 enriched content may indicate however that the Russians have in mind the possibility of constructing a pile using enriched material. This would enable them to use relatively impure graphite or ordinary instead of heavy water.

4. Recent Stalin Awards: It is difficult to deduce why these awards were made after a considerable lapse of time for relatively inferior work although this is in keeping with previous Soviet bureaucratic custom. It may have been either propaganda for domestic and foreign consumption to give the impression that the Russians were well versed in the subject, it may have been to stimulate other Russian scientists working on this subject, or it may have been for later work done by the recipients, the extent of which it was not wished to disclose.

TOP SECRET

5. 5. Activities and Location of Russian Scientists: An interesting report has been received from London giving a summary of interviews with Dr. Ashby, who was until recently scientific attaché to the Australian Legation in Moscow. Dr. Ashby had unusually wide facilities granted him for contacting Russian scientists, but being a biologist, he did not have much contact with scientists of interest to us. According to him Kapitza is still working in Moscow and he describes him as not being a very straight-forward man. From Kapitza's spontaneous outburst when he heard that the first atomic bomb had been dropped, saying that he had not expected it so soon and that he did not know that the Americans and British were so far ahead of Russia, two deductions can be made: one is that Kapitza was informed, although not accurately, of the work on which the Western Allies were engaged, and the other that at the time the bomb was dropped Russia was already working on the project but had not yet produced a bomb. On the other hand, since Stalin was informed officially about the bomb at Potsdam and since Kapitza has a seat on the Soviet Cabinet it is curious that he did not know.

Another point of interest is that the Russian scientists, generally, show no resentment that knowledge about the atomic bomb is being withheld from them since they fully appreciate that the Soviet Government would have withheld the information from us.

According to Dr. Ashby there are four first-class metallurgists, who might well be engaged on the atomic energy problem, working together in Sverdlovsk. Joffe is still in Leningrad.

6. Russian Atomic Energy Programme: With reference to the public statement attributed to Academician Jokel (reference our memorandum dated 17 January): We have been unable to trace anybody of this name. We presume the name may be a misprint for Joffé.

7. The general inference from available but very scanty evidence is that the Russians are only just beginning to study the problem but are straining every effort to master it.

GERMANY

1. German Scientists in Russia: Further information has been received, both from American and British sources, which indicates that the two main groups of scientists of interest to us are located some few miles apart on the eastern shore of the Black Sea somewhere between Suchum and Poti, probably in the neighborhood of Anakliya, but possibly nearer to Suchum. The preponderance of information indicates that Professor Gustav Hertz is engaged on the problem of Isotope separation; Professor Manfred von Ardenne is engaged on cyclotron and electron microscope design, and Professor Max Steenbeck on betatron design. Dr. Riehl is with the Hertz group and since he was previously in charge of uranium metal production at the Auergesellschaft, it is logical to assume that he would continue to have an interest in the same matter in his new location.

We note that London claims to have satisfactory contact with these men via Berlin. One of Dr. Hertz's sons, Helmuth Hertz, is at present in the U.S.A. in a P/W camp. Arrangements have been made to intercept his letters. One such letter from Johannes Hertz indicates his father to be on the Black Sea but the exact location is not given. We hope that before long his father will write to him.

2. The Production of Thorium and Uranium in Germany: Our attention has been drawn to a B.I.O.S. report on this subject by Dr. Roger Potvin. According to this report over six tons of thorium metal and over fourteen tons of uranium metal were produced by Germany up to the end of 1944. The quantity of uranium metal reported appears to be much larger than our previous estimates. We should be glad to receive comment on this figure from London. We are also interested to know what use the thorium metal was put to.

TOP SECRET

- 2 -

TOP SECRET

3. A list of promising young German physicists, prepared by Heisenberg, has been received from the London office.

BELGIUM

1. We note that London is being kept informed at a high level of any political events affecting our interest at this office.

2. We note also that London has not been able to obtain any evidence that recent trade union agitation in the Congo for nationalization of the deposits is officially inspired by a "third party" interest.

BULGARIA

1. Confirmation has been received by this office that the mine mentioned in our memorandum of 17 January is the well-known Goten Mine. We note that London is taking independent steps to ascertain, through a first-class source, fullest details concerning the activities here.

2. Promised samples of the alleged deposit located near the Black Sea cannot be obtained until the snows in the area melt.

3. We note that information recently received from London indicated vigorous activity in the Strelcha area where the Germans were known to have been prospecting in 1942 and 1943, and also activity in the old uranium mining area of Zlatitsa indicated by extensive road work and tunnel blasting between Etropole and Zlatitsa. We presume that London is watching these activities and will report further details that become available.

4. We are trying to obtain confirmation of the report received from London that an ore sample reputed to be from the Murgash Mountain area was flown to this country some months ago by an American officer for analysis. We shall investigate further however.

CZECHOSLOVAKIA

1. Joachimstal Mine: During the period under review various reports have been received at this office concerning activity at the Mine, both from American and British sources. Although many of these reports are conflicting, the preponderance of evidence suggests that there are at any rate a certain number of*technicians working in the Mine, that at least part of the ore is being shipped via Germany, presumably to Russia, that the Mine is closely guarded, and that all activities in relation to the Mine are shrouded in secrecy.

*Russian

A report that there is a secret agreement between the Russian and Czechoslovakian Governments allocating fifty per cent of the Mine's output to Russia has not been confirmed. Such an agreement should, however, not be excluded, having in mind Jan Masaryk's recent well-known utterance at the opening of the UNO Assembly. Careful examination of the transcript of his speech indicates that his statement should be regarded as a warning to the other nations and possibly as an indictment of those members of his Government with whom he is known to be out of sympathy, who may have been responsible for such an agreement. This would explain reports received that he was reprimanded by his Government for having made his statement.

The most recent report indicates that a new building is being constructed in the area which the Russians say is to be a Spa Centre, but which is believed to be intended for a new experimental laboratory.

A further significant point contained in the report recently received from London is that the French Ambassador was about to visit Joachimstal. This may indicate French supply interest.

We note that London is taking steps to have this whole matter elucidated on a high level.

TOP SECRET

- 3 -

TOP SECRET

2. Heavy Water Plant at Wesser: A report has been received of an alleged heavy water plant at Wesser, 17 miles northeast of Parbudice, supposed to be operated by the Russians. Although this report seems unlikely, we would like London to investigate further if possible.

FRANCE

1. Professor Joliot: Information has been received that Professor Joliot is attempting to form a European scientific bloc to counteract the Anglo-American bloc. According to our information he did not receive a sympathetic hearing on the subject from Professor Scherrer when he approached him.

Whilst those who know Joliot most intimately do not believe that he would personally hand over to another power secrets and data of military value to his own country, it is distrubing to know that he has assistants working in his laboratory who are alleged not to be reliable in this respect.

London has been asked to investigate this matter further and also to obtain information about two Russian scientists, Landesburg and Nesmeyanoff, who are reported to be in Paris and have met Joliot on several occasions.

It is perhaps significant that when last in Moscow Joliot was not allowed to visit the Moscow Physics Institute on the pretext, believed to be false, that the Institute had been bombed.

2. Material Resources: A report has been received that Joliot has stated that France has 200 tons of uranium which was not discovered by the Germans. It is not clear whether this refers to stocks held by France prior to the outbreak of war, or whether it might be material which was sent from Belgium to France for safekeeping when the invasion of Belgium appeared imminent. According to other statements attributed to Joliot, deposits of autunite occur in Tonkin in French Indo-China, and French Africa is soon to be surveyed by twenty geologists using airplanes equipped with detecting devices.

FINLAND

A report attributed to Mr. Elias Erkks, a former Foreign Minister of Finland, states that there is an occurrence of uranium in northern Finland somewhere south of Rovaniemi. The deposits are alleged to have been found during the extensive prospecting for cobalt and copper. The occurence is supposed to be known only to Mr. Erkks and his collaborators and has not been revealed to the Germans, while they were in occupation, nor since to the Russians.

We recommend, on the grounds of secrecy, that no action be taken on this information for the time being.

According to a statement by Professor Lennart Siemons, there are no uranium deposits in Finland.

DENMARK

We note from a London report that a Russian Nuclear Physicist named Terletsky visited Copenhagen shortly before Christmas on the pretext of searching for scientific instruments stolen by the Germans. He was shown over the Bohr Institute but no other events of importance are recorded.

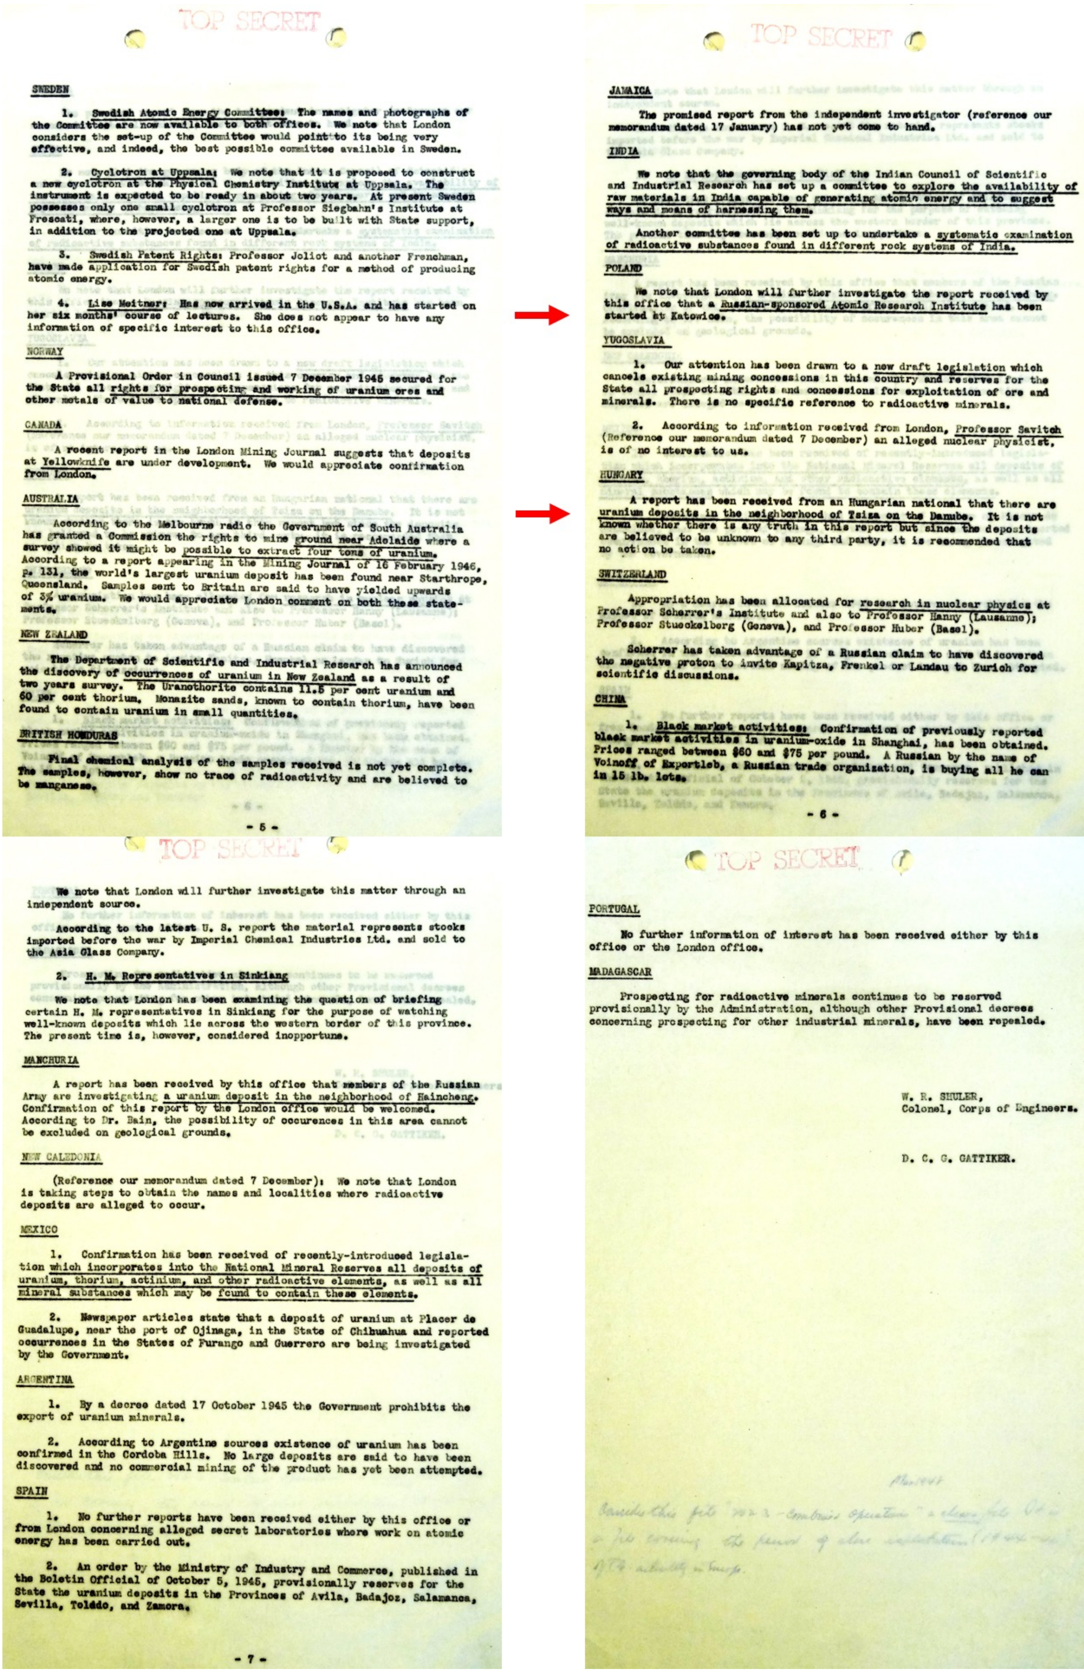
NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.



TOP SECRET

SWEDEN

1. Swedish Atomic Energy Committee: The names and photographs of the Committee are now available to both offices. We note that London considers the set-up of the Committee would point to its being very effective, and indeed, the best possible committee available in Sweden.

2. Cyclotron at Uppsala: We note that it is proposed to construct a new cyclotron at the Physical Chemistry Institute at Uppsala. The instrument is expected to be ready in about two years. At present Sweden possesses only one small cyclotron at Professor Siegbahn's Institute at Frescati, where, however, a larger one is to be built with State support, in addition to the projected one at Uppsala.

3. Swedish Patent Rights: Professor Joliot and another Frenchman, have made application for Swedish patent rights for a method of producing atomic energy.

4. Lise Meitner: Has now arrived in the U.S.A. and has started on her six months' course of lectures. She does not appear to have any information of specific interest to this office.

NORWAY

A Provisional Order in Council issued 7 December 1945 secured for the State all rights for prospecting and working of uranium ores and other metals of value to national defense.

CANADA

A recent report in the London Mining Journal suggests that deposits at Yellowknife are under development. We would appreciate confirmation from London.

AUSTRALIA

According to the Melbourne radio the Government of South Australia has granted a Commission the rights to mine ground near Adelaide where a survey showed it might be possible to extract four tons of uranium. According to a report appearing in the Mining Journal of 16 February 1946, p. 131, the world's largest uranium deposit has been found near Starthrope, Queensland. Samples sent to Britain are said to have yielded upwards of 3% uranium. We would appreciate London comment on both these statements.

NEW ZEALAND

The Department of Scientific and Industrial Research has announced the discovery of occurrences of uranium in New Zealand as a result of two years survey. The Uranothorite contains 11.5 per cent uranium and 60 per cent thorium. Monazite sands, known to contain thorium, have been found to contain uranium in small quantities.

BRITISH HONDURAS

Final chemical analysis of the samples received is not yet complete. The samples, however, show no trace of radioactivity and are believed to be manganese.

- 5 -

TOP SECRET

JAMAICA

The promised report from the independent investigator (reference our memorandum dated 17 January) has not yet come to hand.

INDIA

We note that the governing body of the Indian Council of Scientific and Industrial Research has set up a committee to explore the availability of raw materials in India capable of generating atomic energy and to suggest ways and means of harnessing them.

Another committee has been set up to undertake a systematic examination of radioactive substances found in different rock systems of India.

POLAND

We note that London will further investigate the report received by this office that a Russian-sponsored Atomic Research Institute has been started at Katowice.

YUGOSLAVIA

1. Our attention has been drawn to a new draft legislation which cancels existing mining concessions in this country and reserves for the State all prospecting rights and concessions for exploitation of ore and minerals. There is no specific reference to radioactive minerals.

2. According to information received from London, Professor Savitch (Reference our memorandum dated 7 December) an alleged nuclear physicist, is of no interest to us.

HUNGARY

A report has been received from an Hungarian national that there are uranium deposits in the neighborhood of Tsiza on the Danube. It is not known whether there is any truth in this report but since the deposits are believed to be unknown to any third party, it is recommended that no action be taken.

SWITZERLAND

Appropriation has been allocated for research in nuclear physics at Professor Scherrer's Institute and also to Professor Hanny (Lausanne); Professor Stueckelberg (Geneva), and Professor Huber (Basel).

Scherrer has taken advantage of a Russian claim to have discovered the negative proton to invite Kapitza, Frenkel or Landau to Zurich for scientific discussions.

CHINA

1. Black market activities: Confirmation of previously reported black market activities in uranium-oxide in Shanghai, has been obtained. Prices ranged between $60 and $75 per pound. A Russian by the name of Voinoff of Exportleb, a Russian trade organization, is buying all he can in 15 lb. lots.

- 6 -

TOP SECRET

We note that London will further investigate this matter through an independent source.

According to the latest U. S. report the material represents stocks imported before the war by Imperial Chemical Industries Ltd. and sold to the Asia Glass Company.

2. H. M. Representatives in Sinkiang

We note that London has been examining the question of briefing certain H. M. representatives in Sinkiang for the purpose of watching well-known deposits which lie across the western border of this province. The present time is, however, considered inopportune.

MANCHURIA

A report has been received by this office that members of the Russian Army are investigating a uranium deposit in the neighborhood of Haincheng. Confirmation of this report by the London office would be welcomed. According to Dr. Bain, the possibility of occurences in this area cannot be excluded on geological grounds.

NEW CALEDONIA

(Reference our memorandum dated 7 December): We note that London is taking steps to obtain the names and localities where radioactive deposits are alleged to occur.

MEXICO

1. Confirmation has been received of recently-introduced legislation which incorporates into the National Mineral Reserves all deposits of uranium, thorium, actinium, and other radioactive elements, as well as all mineral substances which may be found to contain these elements.

2. Newspaper articles state that a deposit of uranium at Placer de Guadalupe, near the port of Ojinaga, in the State of Chihuahua and reported occurrences in the States of Furango and Guerrero are being investigated by the Government.

ARGENTINA

1. By a decree dated 17 October 1945 the Government prohibits the export of uranium minerals.

2. According to Argentine sources existence of uranium has been confirmed in the Cordoba Hills. No large deposits are said to have been discovered and no commercial mining of the product has yet been attempted.

SPAIN

1. No further reports have been received either by this office or from London concerning alleged secret laboratories where work on atomic energy has been carried out.

2. An order by the Ministry of Industry and Commerce, published in the Boletin Official of October 5, 1945, provisionally reserves for the State the uranium deposits in the Provinces of Avila, Badajoz, Salamanca, Sevilla, Toldedo, and Zamora.

- 7 -

TOP SECRET

PORTUGAL

No further information of interest has been received either by this office or the London office.

MADAGASCAR

Prospecting for radioactive minerals continues to be reserved provisionally by the Administration, although other Provisional decrees concerning prospecting for other industrial minerals, have been repealed.

W. R. SHULER,
Colonel, Corps of Engineers.

D. C. G. GATTIKER.

Mar 1948

Consider this file "202.3 - Combined Operations" a closed file. It is a file covering the period of close collaboration (1944-46) of [illegible] activity in Europe.

STANDARD FORM NO. 64

Poland

Office Memorandum • UNITED STATES GOVERNMENT

TO : General Groves

FROM : Major Smith

DATE: 21 August 1945

SUBJECT: Polish Radio Broadcast - 18 August 1945.

The following intercepted radio broadcast from Lublin, Poland, is of interest:

> "At a conference in which Minister of Finance, Health and Education Debowski participated has taken place in which it was decided to raise a fund for atomic research. A committee for a fund for atomic research will be established shortly and this committee will consist of a delegate of the government and representatives of Polish science and communities.
>
> The Lord Mayor of Warsaw appealed to the people of Warsaw to raise the fund. It has been reported that uranium has been found near Krzyzowka in Lower Silesia and also large quantities of uranium have been found in zinc blend. Layers of these are found in Silesia.

S-

SMITH

Figure D.109: Postwar report of uranium mines at Krzyzowa and elsewhere in Silesia that were likely worked during the war. It seems unlikely that a completely unexcavated underground deposit of uranium would have been spontaneously discovered immediately after the war, when there were already existing uranium mines plus higher priorities for postwar rebuilding. Francis J. Smith to Leslie Groves. 21 August 1945. SUBJECT: Polish Radio Broadcast—18 August 1945 [NARA RG 77, Entry UD-22A, Box 173, Folder 57.70. Poland Misc].

[There is significant evidence that during the war, Germany was actively mining uranium at multiple sites in Romania for the German nuclear weapons program. Hitler told Romanian Prime Minister Ion Antonescu about some of the results of that program in August 1944 (p. 4594).]

Bomba de la Hiroshima cu uraniu de Băiţa? Exploatarea de uraniu de la Băiţa stârneşte noi controverse. [Hiroshima bomb with uranium from Băiţa? Băiţa uranium mining stirs new controversies.] ***BIHON Ştirile judeţului Bihor.*** **30 January 2015. https://www.bihon.ro/stirile-judetului-bihor/bomba-de-la-hiroshima-cu-uraniu-de-baita-251058/**

Un inginer silvic din Câmpani susţine că din uraniul de la Băiţa s-ar fi construit bombele nucleare de la Hiroshima şi Nagasaki.

Ioan Costea, autorul volumului lansat la finele anului trecut “Uraniul primelor bombe”, a avut o copilărie marcată de poveştile rudelor despre invazia nemţilor în Apuseni. Omul susţine că în laboratoarele secrete ale SS-ului a fost prelucrat uraniul din Băiţa şi că pentru a fi transportat a fost construit viaductul peste Valea Luncoiului. Ioan Costea invocă rapoarte geologice care pomenesc de prospecţiuni făcute de nemţi. “Probabil ca au scos suficient pentru a face o bombă”, spune Ioan Costea, în cartea sa. Autorul recunoaşte că volumul nu are caracter ştiinţific şi că e construit doar pe baza dovezilor, documentelor şi mărturiilor pe care a reuşit să le strângă. [...] “Tot căutând informaţii oficiale care să arate, aşa cum ar fi de aşteptat, că sovieticii au început exploatarea uraniului românesc, nu mică mi-a fost mirarea să descopar că Hitler a fost primul care a început exploatarea uraniului în munţii moţilor. Am aflat că naziştii lui Himmler au folosit o parte a acestui uraniu la construirea câtorva “arme atomice”...Cealaltă parte a uraniului moţilor a ajuns în posesia statului american. Din acest uraniu, dăruit de nazişti, americanii au făcut acele bombe pe care le-au slobozit asupra Japoniei”.

A forestry engineer from Câmpani claims that uranium from Băiţa was used to build the nuclear bombs of Hiroshima and Nagasaki.

Ioan Costea, author of the book *Uranium of the First Bombs*, published at the end of last year, had a childhood marked by stories from relatives about the German invasion of the Apuseni mountains. The man claims that uranium from Baita was processed in secret SS laboratories and that the viaduct across the Luncoiului Valley was built to transport it. Ioan Costea cites geological reports mentioning prospecting by the Germans. “They probably dug up enough to make a bomb,” says Ioan Costea in his book. The author admits that the volume is not scientific and is built solely on the evidence, documents and testimonies he has managed to collect. [...] “Still searching for official information showing, as might be expected, that the Soviets had begun mining Romanian uranium, I was not a little surprised to discover that Hitler was the first to begin mining uranium in the mountains. I found out that Himmler’s Nazis used part of this uranium to build some “atomic weapons”... The other part of the mountains’ uranium came into the possession of the American state. From this uranium, given to them by the Nazis, the Americans made those bombs they dropped on Japan.”

Sabina Paşca fosta soţie a unuia dintre primarii de Arieşeni şi-a amintit că în a doua decadă a anilor'30: "Oamenii din Arieşeni mergeau la lucru la Băiţa Plai cu caii, pe la Colibiţa, pe un drum de picior" şi că exploatau "un fel de praf de puşcă, care-i mai scump decât aurul. O mâna de praf de puşcă de la Băiţa face cât patru mâini de aur". Gheorge Trifon şi-a amintit că în 1995 a fost plătit de un ofiţer rus să întocmească o reţea de 100/100 m pentru detectarea uraniului pe versantul Râului Arieş – Muntele Biharia. "Iţi pot spune cu certitudine că atât harta, cât şi aparatura erau nemteşti", a subliniat omul. [...]

"În această carte arăt că naziştii au dus uraniu din România, în special din zona Băiţa (Biharia) dar am aflat recent că şi din Cheia (Rimetea), de la Cataractele Lotrului şi din Ciudanoviţa–Caransebeş. Din aceste locuri, nemţii le spuneau localnicilor că duceau orice altceva decât uraniu: molibden, cuarţ, piatră de construcţie, aur, cupru etc.Interesant este ca Biharia a deţinut şi încă mai deţine faimosul uraninit (un oxid de uraniu, pechblenda). Se ştie că ruşii, care aveau la finele anului 1944 numai 1 kg de uraniu, au ridicat cu japca din Germania, în perioada apr–iulie 1945, cca 400 tone de uraninit. Să amintim pe scurt şi uraniul ridicat de americani, care, la rândul lor, au golit de uraniu toată partea Germaniei care le-a revenit. Să ţinem seama şi de faptul ca nemţii au transportat cât au putut uraniu din estul spre vestul Germaniei, spre zona americană a Germaniei, pentru a se pune bine cu americanii. Nu pretind că tot uraninitul din Germania, dus de americani, ruşi şi poate şi britanici sau francezi, ar fi provenit din România (putea fi din Cehia, Congo belgian sau din Germania). Important este că cel mai mult uraninit a fost din România şi consider că suntem îndreptăţiţi să aflăm odata cu valoarea exporturilor neplătite şi numele articolelor exportate în perioada nazistă.

Sabina Paşca, the ex-wife of one of the mayors of Arieşeni, recalled that in the second decade of the 1930s: "The people of Arieşeni used to go to work at Băiţa Plai with their horses, on the Colibiţa footpath" and that they mined "a kind of gunpowder, which is more expensive than gold. A handful of gunpowder from Băiţa is worth four hands of gold." Gheorge Trifon recalled that in 1995 he was paid by a Russian officer to draw up a 100/100 m grid for detecting uranium on the Arieş River–Biharia Mountain slope. "I can tell you with certainty that both the map and the equipment were German," the man stressed. [...]

"In this book I show that the Nazis took uranium from Romania, especially from the Băiţa (Biharia) area, but I have recently learned also from Cheia (Rimetea), from Cataractele Lotrului and from Ciudanoviţa–Caransebeş. From these places, the Germans used to tell the locals that they were carrying anything other than uranium: molybdenum, quartz, building stone, gold, copper, etc. Interestingly, Biharia had and still has the famous uraninite (an oxide of uranium, pitchblende). It is known that the Russians, who had only 1 kg of uranium at the end of 1944, collected about 400 tonnes of uraninite from Germany in April–July 1945. Let's also briefly mention the uranium collected by the Americans, who in turn emptied the entire part of Germany that was theirs. Let's also bear in mind that the Germans transported as much uranium as they could from East to West Germany, to the American part of Germany, in order to get in good with the Americans. I'm not claiming that all the uranium in Germany, carried by the Americans, Russians and maybe the British or French, would have come from Romania (it could have come from the Czech Republic, Belgian Congo or Germany). What is important is that most of the uraninite was from Romania, and I think we are entitled to know along with the value of the unpaid exports the names of the items exported during the Nazi period."

Andrei Dicu and Sorin Dumitrescu. 2019. Bomba atomică ruso-americană, hrănită din uraniul românesc [Russian-American Atomic Bombs, Fed by Romanian Uranium]. *Taifasuri* 748.
http://taifasuri.ro/index.php/taifasuri/mozaic/17838-bomba-atomica-ruso-americana-hranita-din-uraniul-romanesc-nr748-sapt19-25-sept-2019

Aurul şi metalele preţioase din Munţii Apuseni au făcut deliciul multor subiecte de presă. Există, însă, un zăcământ incomparabil mai valoros şi "mai" strategic decât aurul sau cuprul. Uraniul, un metal extrem de preţios, mai ales în producerea bombelor atomice, ne-a stat în palmă, până când, ca de obicei, au venit alţii să se hrănească din valorile noastre.

La început a fost Hitler...

Primul care a scris despre acest subiect a fost Ioan Costea, un moţ care, inginer silvic fiind, a lucrat în pădurile şi în păşunile a şase comune (Horea, Albac, Scărişoara, Beliş, Vadu Moţilor şi Gârda), unde, printre altele, a scormonit rămăşiţele rezistenţei anticomuniste a legionarilor şi a partizanilor care au luptat împotriva noii orânduiri. Tot căutând prin munţi după informaţii care să arate că ruşii au început exploatarea uraniului românesc imediat după 23 august 1944, oricum măcar înainte de 1949, când a fost detonată prima bombă nucleară sovietică, nu mică i-a fost mirarea să descopere că, de fapt, Hitler a fost primul care a început exploatarea uraniului, în Munţii Apuseni. [...] Şi aceste exploatări au fost taman în Munţii Apuseni, mai exact în Biharia, la Ştei-Băiţa. Se pare că zăcămintele de uraniu de aici au fost descoperite de aviatorii nemţi care, prin 1938–1939, survolând perimetrul, au observat o scădere de presiune şi o developare bizară a filmelor, fapt care i-a determinat pe germani să facă o cercetare geologică a zonei, cu aparatură modernă, astfel că au instalat 40 de sonde în acea arie.

Gold and precious metals in the Apuseni Mountains have been the subject of much media coverage. But there is an incomparably more valuable and strategic deposit than gold or copper. Uranium, an extremely precious metal, especially in the production of atomic bombs, sat in the palm of our hands until, as usual, others came to feed on our resources.

First it was Hitler...

The first to write on this subject was Ioan Costea, a Moor who, being a forestry engineer, worked in the forests and pastures of six communes (Horea, Albac, Scărişoara, Beliş, Vadu Moţilor and Gârda), where, among other things, he excavated the remains of the anti-communist resistance of the legionaries and partisans who fought against the new order. While searching the mountains for information showing that the Russians had started exploiting Romanian uranium immediately after 23 August 1944, at least before 1949, when the first Soviet nuclear bomb was detonated, he was not a little surprised to discover that it was in fact Hitler who was the first to start exploiting uranium in the Apuseni Mountains. [...] And those mines were in the Apuseni Mountains, in Biharia, at Ştei-Băiţa. It seems that the uranium deposits here were discovered by German aviators who, around 1938–1939, flying over the perimeter, noticed a drop in pressure and a bizarre development of the films, which led the Germans to carry out a geological survey of the area with modern equipment, so they installed 40 probes in the area.

“Un praf de puşcă mai scump ca aurul”

Mulţi dintre localnici povesteau că au luat parte la aceste măsurători, de la care s-au obţinut informaţii că aparatura şi hărţile erau nemţeşti şi că, odată ajunşi în zona Biharia, toate aparatele s-au ars din pricina concentraţiei mari de uraniu. Ce exploatau nemţii? După mărturia unui sătean, “un fel de praf de puşcă, probabil mai scump ca aurul, iar o mână cu praf de puşcă de Băiţa făcea cât patru mâini cu aur”. Uraniul care a fost obţinut din acele exploatări a fost ambalat în caserole de plumb, pentru a preveni iradierea, care au fost transportate la Brad. Acolo erau preluate de serviciul SS şi expediate la laboratoarele din Germania. Pentru a înlesni transportul la scară industrială, nemţii au construit tronsoane noi ale drumului Avram Iancu-Bulzeşti-Baia de Criş şi au finalizat o parte a căii ferate Brad–Deva, o megastructură dotată cu viaducte şi cu tunele impecabile. După invazia sovietică, lucrurile s-au schimbat. În august 1949, când a fost detonată, oficial, prima bombă atomică rusească, întreprinderea Sovrom, sovieto-română, Rom-Kuartit a început exploatarea uraniului. Potrivit istoricului Dan Silviu Boerescu, spionajul şi prospecţiunile ruşilor au început înainte de 23 august 1944 şi au fost urmate de exploatările din zona Băiţa-Arieşeni, Vidra şi probabil din Valea Ierii, iar cel puţin o parte din uraniul provenit din Munţii Apuseni a fost folosit la fabricarea primei bombe atomice sovietice. [...]

“Gunpowder more expensive than gold”

Many of the locals told how they had taken part in these measurements, from which information was obtained that the equipment and maps were German and that, once they arrived in the Biharia area, all the equipment had burned up because of the high concentration of uranium. What were the Germans exploiting? According to one villager, “a kind of gunpowder, probably more expensive than gold, and a handful of Biita gunpowder was as much as four hands of gold.” The uranium that was obtained from those mines was packed in lead casseroles to prevent irradiation, which were transported to Brad. There they were picked up by the SS service and shipped to laboratories in Germany. To facilitate transport on an industrial scale, the Germans built new sections of the Avram Iancu-Bulzeşti-Baia de Criş road and completed part of the Brad–Deva railway, a megastructure with viaducts and impeccable tunnels. After the Soviet invasion, things changed. In August 1949, when the first Russian atomic bomb was officially detonated, the Soviet-Romanian enterprise Sovrom, Rom-Kuartit, began mining uranium. According to historian Dan Silviu Boerescu, Russian spying and prospecting began before 23 August 1944 and was followed by mining in the Băiţa-Arieşeni, Vidra and probably in the Ierii Valley, and at least some of the uranium from the Apuseni Mountains was used to make the first Soviet atomic bomb. [...]

Pavel Sudoplatov, unul dintre adjuncţii lui Beria (fost lider comunist care a intrat în conflict cu Stalin şi a fost asasinat) şi un fel de Himmler al ruşilor, a scris în cartea sa, “Misiuni speciale”, că liderul sovietic era la fel de ahtiat ca şi Hitler în privinţa construirii bombei atomice. KGB-ul a aflat despre exploatarea uraniului din Ţara Moţilor de la comuniştii evrei care prestaseră muncă silnică, sub supravegherea trupelor germane aflate în România. Sudoplatov vorbeşte despre munţii noştri, dar şi despre exploatările care au avut loc la Bukovo, în Bulgaria. Se pare că după ce Germania a pierdut războiul, echipele de misiuni speciale ruseşti şi americane, antrenate în tot ceea ce înseamnă uraniu şi intitulate ALSOS, au găsit la nazişti cantităţi uriaşe de “combustibil”, care era deja apt pentru utilizare.	Pavel Sudoplatov, one of Beria’s deputies (a former Communist leader who clashed with Stalin and was assassinated) and a sort of Himmler of the Russians, wrote in his book, *Special Missions*, that the Soviet leader was as eager as Hitler to build the atomic bomb. The KGB had learned about uranium mining in the Mote Country from Jewish Communists who had been doing forced labour under the supervision of German troops in Romania. Sudoplatov talks about our mountains, but also about mining in Bukovo in Bulgaria. It seems that after Germany lost the war, Russian and American special mission teams, trained in all things uranium and called ALSOS, found huge quantities of “fuel” with the Nazis, which was already fit for use.

Gheorghe Banciu, Ovidiu Banciu, Liviu Suciu, and Constantin Cosma. 2012. Mining Activities in the Superior Basin of Crişul Negru River. *Ecoterra—Journal of Environmental Research and Protection* 33:1–6.

Short history of mining activities in the area. From the subsoil of this region man has exploited many mineral resources such as: gold, silver, iron, copper, lead, zinc, molybdenum, bismuth, wolfram, nickel, cobalt, pyrite, limestone, marble, building face stones and uranium since the Middle Ages. In the beginning, gold and silver has been extracted by the local population. Around 1600, iron compounds have been also extracted, and after 1700, mining activities have increased including the exploitation of lead and zinc. In 1880, 7000 kg of copper, 1567 kg of silver, 5300 kg of lead have been extracted from Băiţa-Bihor area. Around 1890, important molybdenum and bismuth ores have been identified. During the First World War, the extraction of molybdenum has been taken over by a German company as this compound was used in for making cannons. Since 1935, the molybdenum mine was exploited by different Romanian companies. The most intense mining activities concerning non-ferrous mineral resources extraction have been carried out from 1960 until around the early 1990s[...]

Uranium ore mining (1949–1999). Uranium ore geological prospection has been carried out independently in three phases by Romanian geologists (in 1930s), German teams (1943–1944) and by the Soviets (1945–1960), the last two phases being determined by the geopolitical situation of our country at that time. From the Romanian scholars who brought their contribution to the identification of the presence of uranium ores in this region, we can mention professor of geology Popescu-Voinesti, and geologist Dan Giusca who identified and collected uranium bearing minerals from this region, but were not successful in delimiting the exact location of the ore.

14 September 1945

The following information was received from MIS -

HULUBEI, Horia

Rumanian scientiest - field, Chemistry

Discovered a new element "Moldavium"
Studied and did research work in Paris.
Appointed Dean of Bucharest University in 1941.
In 1944 visited as president of board of Resitza Works (armaments)
President of Finnish-Rumanian Society
Has the following decorations -
Crown of Rumania
German Eagle with stars
Reported to be pro-Nazi

NARA RG 77, Entry UD-22A,
Box 160, Folder Apr 45—Dec. '45

Figure D.111: Horia Hulubei was a Romanian nuclear scientist who worked in the Soviet nuclear weapons program after the war. During the war he and Romania supported the Third Reich—what exactly did he work on during that time? Did the Resitza Works do any nuclear-related work? [NARA RG 77, Entry UD-22A, Box 160, Folder APR 45–Dec. '45]

Uranium and thorium removed from Germany by the United States and Soviet Union [translated and adapted from Nagel 2016, pp. 543–547]

Taken by United States

Garmisch: uranium
Haigerloch: 1.5 tons uranium metal
Oolen (Belgium): 80 tons uranium ore
Stadtilm: 10 tons uranium oxide
Stassfurt (Kalischacht): uranium ore for Auer 1100–1200 tons
WiFo Leopoldshall (near Calbe): ?? tons uranium ore
Toulouse: 30 tons uranium ore
U-234 submarine: 560 kg uranium oxide (enriched?)

Announced total taken by United States:
Approximately 1200 tons uranium, mostly unprocessed ore

Taken by Soviet Union

Berlin (Auer): uranium oxide
Berlin (KWI Ph): 250 kg uranium metal, 3 tons uranium oxide
Berlin (Schering): 1500 kg thorium oxalate, 50 kg thorotrast
Berlin (Toran): 30 kg mesothorium
Berlin-Grunau (Auer/Degussa): 100 kg uranium products
Goldberg (Mecklenburg): 70 tons? uranium compounds, stored by Roges in Hoffmann and Malzew warehouse
Johanngeorgenstadt (mine): uranium oxide
Kummersdorf (Gottow): 3.5 tons uranium oxide
Landsberg/Warthe: uranium oxide
Neustadt-Glewe (Mecklenburg): 100 tons uranium oxide, stored by Roges in Hoffmann and Molzen warehouse
Oranienburg (Auer): 100 tons uranium oxide, Monazit 1340 tons
Radebeul (Heyden): 300 kg thorium products, 100 kg monazite sand
Schneeberg (mine): uranium oxide
Wien: 560 kg U-Metall 24 kg uranium oxide
Zeuthen/Miersdorf (Reichspost): APS uranium oxide

Announced total taken by Soviet Union
Approximately 300 tons uranium
(not counting vastly more which was extracted from the mines 1945–1989)
Approximately 1340 tons of thorium, mostly unprocessed ore

[These estimates are based on numbers in various individual reports that have been released by the United States and Russia. There may well have been significant amounts of uranium or thorium that were not covered in those reports but that were removed by the United States, Russia, United Kingdom, or France. It is also possible that Germany concealed or disposed of significant amounts, or sent them to other countries.

Some of the seized uranium is still being analyzed. See for example ACS 2021.]

Office Memorandum • UNITED STATES GOVERNMENT

TO : Major General L. R. Groves DATE: 14 June 1945

FROM : Major F. J. Smith

SUBJECT: Captured Material

1. Lt. Warner landed in New York City last night. He is accompanying the shipment of captured material comprising approximately 31 tons of heavy water which is stored in 39 metal drums and 70 wooden barrels. He also has 10 cases of 6 cubic foot content each of U powder and cubes, 2 cases of 12 cubic foot content each of U powder and cubes, and 60 cases of ½ cubic foot content each of U powder and cubes. The shipment is aboard the freighter James B. Richardson which will dock and unload at Pier 17, East River, New York City, at 9:30 this morning. Arrangements have been made with Major Kelley's office to have trucks available to transport the material to the Madison Square Area warehouse at E. 73d St., NYC.

2. The British on a previous occasion had requested us to turn over the heavy water to them. If you desire to turn over this material to the British I would like to know so that I can make arrangements with Major Kelley to transship the material.

SMITH

3) Major Vance will store material in U.S. Govt Warehouse, Middlesex N.J.

4) Major Traynor will make arrangements for testing of heavy water and will submit recommendations for its proper disposal.

5) Will keep you advised of all further proceedings.

SECRET

12:25 p.m.
16 June 1945 Lt. Warner called Major Smith from New York City.

Gave following description of shipment he accompanied to States:

- 39 steel drums, 1000 lbs. each, containing liquid. Heavy water
- 159 wooden kegs, 125 lbs. each, containing yellow powder. " "
- 37 small boxes measuring 12" square by 6" depth, containing metal plates. U plates
- 81 small boxes of approximately same size containing black bricks. U
- 6 steel drums containing yellow powder. U
- 2 large boxes about the size of a desk, containing instruments. 3 ft. x 6 ft.
- 2 long boxes, 12" x 12" x 8 feet, containing instruments.
- 1 box about 4 foot square containing jug.
- 18 crates of assorted sizes containing material unknown to Lt. Warner. Average size of crate with 6 foot cubic content.

Above weights are estimated only.

NO 3 OF 3 COPIES, SERIES A

11 April 1946

Subject: Professor Smyth and Uranium Oxide in Germany

To: Lt. Col. E. P. Dean, Office of Military Attache, American Embassy, London, England

1. Reference is made to letter on above subject dated 15 March 1946.

2. Dr. C. P. Smyth was interviewed by Mr. Lowenhaupt of this office at Princeton, New Jersey, on 2 April 1946. Dr. Smyth after consulting his records stated that he had observed uranium in tonnage lots at the following places in Germany:

a. Three to five tons at Bad Tolz in the custody of Dr. Fritz Rehbein. Sent to U.S.

b. Approximately six tons at Riedel de Haen, A. G. in Seelze bei Hannover.

c. A large amount at Stassfurt which Dr. Smyth had observed the British removing. Sent to U.S.

d. Three tons of raw concentrated ore and four tons of ammonium uranate of Katanga origin at the Büchler Chemische Fabrik in Boersum between Brauschweig and the Hartz, near the northern edge of the Hartz.

e. An undetermined amount at the Auergesellschaft plant at Treibach near Klagenfirth. (Hearsay)

3. Although at the time he was unable to uncover any hidden caches, Dr. Smyth stated that he suspected the presence of fair amounts of uranium at:

a. Kirchner's Physikalische Institute von Köln at Kochelberg 2, Garmisch Partenkirchen. Sent to U.S.

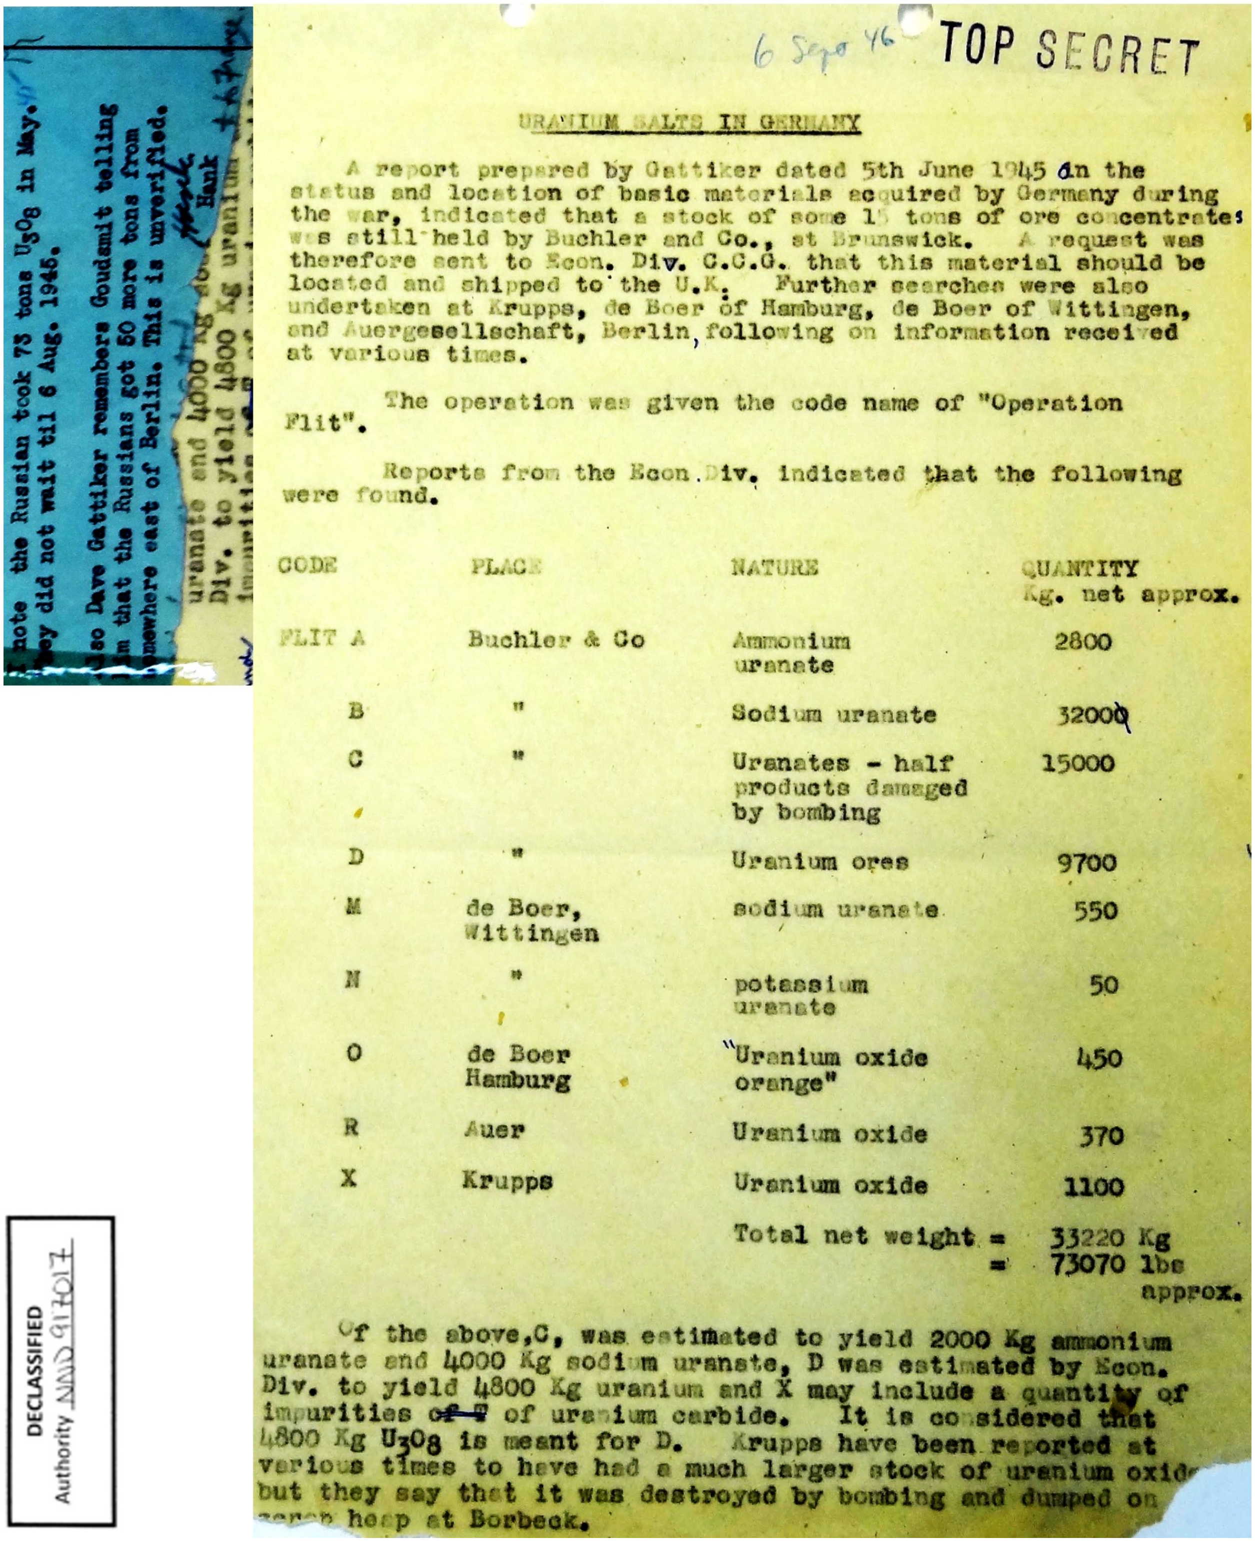
b. Zweitte Physikalische Institute Vien at Thumersbach across Lake Szell from Szell am Zee. Russians got while in Vienna

4. Dr. Smyth further stated that the presence of uranium in the above places had been reported by him to the military authorities of the Alsos Mission, and that it had been their responsibility to remove the uranium.

W. R. SHULER,
Colonel, Corps of Engineers.

Figure D.115: W. R. Shuler to E. P. Dean. 11 April 1946. Subject: Professor Smyth and Uranium Oxide in Germany. This highly incomplete list illustrates the variety of places that processed, stored, and used uranium during the war, as well as the various Allied groups that stumbled across some of those after the war [NARA RG 77, Entry UD-22A, Box 169, Folder 32.32. Germ. Ind. TA].

NARA RG 77, Entry UD-22A, Box 169, Folder 32.32 Germ. Ind. TA



I note the Russian took 73 tons U_3O_8 in May. They did not wait til 6 Aug. 1945.

Also Dave Gattiker remembers Goudsmit telling him that the Russians got 50 more tons from somewhere east of Berlin. This is unverified.

Hank

6 Sept 46

TOP SECRET

URANIUM SALTS IN GERMANY

A report prepared by Gattiker dated 5th June 1945 on the status and location of basic materials acquired by Germany during the war, indicated that a stock of some 15 tons of ore concentrates was still held by Buchler and Co., at Brunswick. A request was therefore sent to Econ. Div. C.C.G. that this material should be located and shipped to the U.K. Further searches were also undertaken at Krupps, de Boer of Hamburg, de Boer of Wittingen, and Auergesellschaft, Berlin, following on information received at various times.

The operation was given the code name of "Operation Flit".

Reports from the Econ. Div. indicated that the following were found.

CODE	PLACE	NATURE	QUANTITY Kg. net approx.
FLIT A	Buchler & Co	Ammonium uranate	2800
B	"	Sodium uranate	32000
C	"	Uranates - half products damaged by bombing	15000
D	"	Uranium ores	9700
M	de Boer, Wittingen	sodium uranate	550
N	"	potassium uranate	50
O	de Boer Hamburg	"Uranium oxide orange"	450
R	Auer	Uranium oxide	370
X	Krupps	Uranium oxide	1100
		Total net weight =	33220 Kg = 73070 lbs approx.

Of the above, C, was estimated to yield 2000 Kg ammonium uranate and 4000 Kg sodium uranate, D was estimated by Econ. Div. to yield 4800 Kg uranium and X may include a quantity of impurities ~~of T~~ of uranium carbide. It is considered that 4800 Kg U_3O_8 is meant for D. Krupps have been reported at various times to have had a much larger stock of uranium oxide but they say that it was destroyed by bombing and dumped on scrap heap at Borbeck.

Air transport of the material in the above table was arranged to Bassingbourne aerodrome, whence the material was taken by road to Harwell.

Much of the material was badly packed in barrels not sufficiently strong for the weight of material they contained. Hence many burst or were broken during the several handlings they received. Repacking at Bassingbourne has probably resulted in the mixing of some of the lots.

The net and gross weights and identifying letters are not clearly marked on all the packages. An approximate estimate has been made of the net quantities held at Harwell as follows:

CODE	NUMBER OF PACKAGES	NET CONTENTS lbs.
A/B	114	15,000
C	75	34,800
D	54	19,800
M	11	1,400
N	1	100
O	7	1,300
R	2	800
X	23	2,300
	TOTAL =	75,500 lbs.
	=	33.7 tons

In view of the fact that these figures are estimated from a visual inspection only, the agreement with the Econ. Div. report of 73,070 lbs. is considered reasonable.

It is estimated that the 75,500 lbs represents approximately an amount of 45,500 lbs. or 20 tons of U_3O_8, of which 18 tons came from Buchler and Co. According to Gattiker's table an amount of 25 tons was outstanding between de Boer of Wittingen, Buchler and Krupps, of which 14½ tons was credited to Krupps. It is known that Krupps did not receive the full quantity which they were empowered to order but the bulk of their supply according to records came from de Boer of Hamburg. Since Buchler was one of the three firms authorised to handle uranium, it is probable that later they were handling the Krupp order, particularly as Krupp wanted the uranium as U_3O_8 while the de Boer stocks seem to have been sodium and potassium salts. On the other hand the Buchler stocks may have belonged to Auer or to Chemische Fabrik Grunau or to Hoffman and Molsen, all of whom were subject to

TOP SECRET

-3-

bombing and who sent their stocks away for safe storing. It is believed that the latter two firms stored their stocks at Neustadt-Glewe. Whatever the explanation of Buchler's excess stock it is certain that they were very unwilling to disclose its presence.

Gattiker's report further suggests that 71 tons U_3O_8 equivalent were held by Auergesellschaft at Oranienburg and Berlin. A recent interrogation of Dr. Ihwe of Auer yielded the information that about 23 tons U_3O_8 equivalent were at Oranienburg in May 1945, and that some 50 tons belonging to the H.W.A. were stored in the Berlin factory. This latter was removed by the Russians in May 1945. Gattiker's report credits the H.W.A. with 9 tons U_3O_8 hence there is an amount of (71+9) - (23+50) = 7 tons unaccounted for. This maybe part of Buchler's stock.

The Oranienburg works have apparently been completely stripped by the Russians, even to the extent of removing the entire wreckage from the part of the factory which housed the uranium salts. A small quantity of only 800 lbs. U_3O_8 has been discovered at the Berlin works and evacuated as Flit R.

The U.S. authorities have also located a quantity of approximately 7-9 tons of ammonium uranate and yellow oxide at Degussa, Frankfurt-a-Maine. They propose to evacuate this material to the U.K. to be added to the stocks at Harwell. The total stock comprising the Colen material formerly at Broome Manor, Operation Flit material and the Degussa stock will then be evacuated together to the U.S. With respect to this lot, Gattiker's report states Degussa should have a stock of 25 tons of crude sodium uranate (50% U_3O_8 equivalent) and possibly 14 tons of refined products, which latter he assumes to have been used to make compressed oxide blocks and metal for the K.W.I fuer Physik. When Degussa was visited by an Alsos party in May-June 1945 no stocks were found. He also assumes that the crude salt stocks had been evacuated to Buchler or to the evacuation works of Auer. Thus the present find represents approximately either one half or one quarter of the possible Degussa stocks depending on whether the refined products are assumed to have been used to supply the K.W.I. fuer Physik demand or not.

A further quantity of between 200 and 1000 lbs of probably U_3O_8 is held at Halstead Place and is to be removed to Harwell at some future date. This material probably came either from Krupp's Widia Fabrik or else from Gebruder Borchers at Goslar, who were cooperating with Krupps in the production of uranium carbide and metal.

SUMMARY AND CONCLUSION

A quantity of approximately 75,500 lbs. of Uranium oxide and salts has been removed from the British zone of Germany to Harwell. This is equivalent to approximately 20 tons U_3O_8 It is recommended that the bulk of the material be repacked in secure containers, and weighed, before shipping to the U.S. A further 7-9 tons from the U.S. zone is being added to this quantity making a total of some 26 tons U_3O_8 equivalent, or approximately 34 tons of various products.

6th September 1946.

SECRET 1 cy of 1

URANIUM EVACUATED FROM THE E.T.O.

17 Apr 45 8 tons U-oxide removed from Stadtilm. Probably sent to England.

27 Apr 45 11 tons U-salts from Radium Chemie Co., Frankfurt removed by Maj. Furman, U.S.Army(ALSOS). No indication of where removed to.

7 May 45 $4\frac{1}{2}$ tons metal cubes from Paris sent to Oak Ridge.

21 May 45 1097 tons U-products arrived in U.K. evacuated from Stassfurt. This was shipped to the U.S. the last 190 tons leaving England 26 Jan 46.

13 June 45 Lt. Warner arrived N.Y. with U-powder and cubes (est. 1500 lbs.)

5 Apr 46 About 6 tons arrived N.Y.C. on Hagerstown Victory. Origin - 5 tons from Bad Tolz and Munich; $1\frac{1}{2}$ tons from Garmisch. Was U-oxide.

Sometime in '46 33.7 tons U-salts were evacuated by the British to Harwell. This had been picked up them from 4 German concerns, Buchler , de Boer, Auer and Krupps. It was supposed to be shipped eventually to the U.S. along with about 12 tons U-oxide which were evacuated from Degussa, Frankfurt am Main, to Britain in Oct. '46.

On 1 & 2 Oct 44 there were removed to England from Oolen, Belgium 46.6 tons of refin~~d~~ed U. made out of 79 tons sent back by the Germans to Oolen, its origin, from the U stock captured by them at Le Havre. Another 70 tons of this the French managed to get away to the south of France. Of this Alsos located 30 tons and shipped it to the U.S. via Marseilles. It arrived here 9 Nov 44.

Michael Howard. 2010 *Otherwise Occupied*, pp. 156–158.

[September 1946, British-occupied zone of Germany:]

One night I was called in the early hours on one of the two telephones by my bed, and a codeword was muttered conspiratorially in my ear. It meant absolutely nothing to me; I had simply not been briefed in advance. It was the GSO2 at HQ T-Force, and he had no option but to identify himself, and to explain to me 'in clear' what the operation consisted of. There were said to be eleven thousand kilos of highly refined uranium ore lying in a loose pile in the cellars of Krupp's Widia Works at Essen (whose main business was in carbide steels). A quadripartite team including four Russians was due to be visiting the site in a couple of days and it was vitally important that there should be no trace of the uranium remaining by the time they arrived, or they would be entitled to make a bid for it. How on earth had it been left sitting there so long?

Nothing for it but to get straight on the phone to Fred Bonney at B Detachment at Heisingen, not five miles from Krupp's Widia Works, and tell him the story in clear. He set to work immediately, and they rustled up from somewhere enough empty steel three-inch mortar bomb boxes, with a handle at each end, which limited the contents to a weight of this dense material that required no more than two men to lift. The entire heap, every scrap, was boxed and loaded onto a ten-ton Mack truck and delivered to me by early afternoon at Kamen. The springs of the truck bore the gross weight of the uranium plus the mortar-bomb boxes surprisingly well. I collared the Mess corporal, Corporal Weatherall, and told him to draw a Sten gun and a couple of magazines, sit on the load, take it up to the RAF at Bückeburg, '...and if any bastard tries to take it away from you, shoot him. And get a receipt.' Which he did, from a squadron leader, for 11,000 kilos.

The material was almost certainly 'yellowcake', a form of triuranium octoxide[...]

About six months later a captain in the Special Investigation Branch (SIB) asked to come and see me. The RAF had weighed the bomb boxes for their own purposes before flying them over to England, but the net weight of the contents was never established until the boxes reached their final destination, when it was found to be 6,000 kilos. It was meant to have been 11,000. Where were the missing 5,000 kilos? 'Search me,' I said. The SIB spent quite a while nosing round, and the only conclusion they could reach was that there had never been 11,000 kilos at Krupp's Widia Works in the first place. As there was no weighing equipment accessible to where the material had been dumped, it had been an estimate, and an inaccurate one. Or had someone in Krupp's been squirreling away a couple of kilos at a time for sixteen months, and had it since crossed the border of Magdeburg [into the Soviet-occupied zone of Germany] in quantities which would go in a haversack? It was a conclusion they shied away from. The pile had appeared undisturbed.

[Michael Howard (British, 1926–2018) was an intelligence officer in the British T-Force, which investigated and removed vast amounts of technology from Germany after the war. This incident that he recounted is important because it demonstrated that:

- Nations other than just the United States and the Soviet Union removed tons of uranium from German territory after the war. (In this case it was the United Kingdom, but perhaps France or maybe even other countries did as well.)

- The discovery and removal of this stockpile of uranium does not appear to be mentioned in official documents that have been released. If Howard had not described it in his memoirs before he died, the public would still be entirely unaware of this incident. What other discoveries of uranium or other aspects of the German nuclear program also remain unreleased to the public?

- As late as at least September 1946, there were large stashes of German uranium that had not already been discovered and removed by Allied forces. Perhaps there were other stockpiles of German uranium (e.g., in underground facilities) that Allied forces continued to overlook, and that remain hidden to this day.

- Uranium was at facilities that had not been believed to be part of the German nuclear program. Why was highly refined uranium oxide at Krupp? Did Krupp (which had extensive expertise with metallurgy) play an important role in the German nuclear program, for example by fabricating uranium metal components for reactors or bombs? Or was the uranium simply dumped there as a hiding place near the end of the war?]

National Intelligence Survey (NIS) 26 (U.S.S.R.), Chapter VII, Section 73 (Atomic Energy). 1955. CIA. https://www.cia.gov/readingroom/docs/DOC_0000198124.pdf https://www.cia.gov/readingroom/document/0000198124 [This report demonstrates that most of the uranium mined for the postwar Soviet nuclear weapons program came from regions that were under German control during World War II. This report explicitly states that several of those uranium sources were exploited by Germany during the war. There is independent evidence that a number of the other sources listed here were also used by Germany during the war. Thus wartime Germany had access to an enormous amount of uranium from these regions—plus the Congolese high-grade uranium ore that Germany obtained from Belgium. Moe Berg's notes (pp. 5051–5063) reference a 1951 version of this report that I have not been able to obtain.]

1. Uranium Supply

Current internal mining operations provide about one third of the estimated annual uranium production available to the USSR. The remaining two thirds are obtained from Germany, Czechoslovakia, Bulgaria, Romania, Poland, and China. Of these latter sources, Germany and Czechoslovakia are outstanding in that they provide almost 90 per cent of the total produced outside the USSR. [...]

a. USSR Sources [...]

b. German Sources

(1) Ore deposits—Deposits in the Soviet Zone of Germany are at present the most productive source of uranium being exploited by the Soviets. It is estimated that this source provided about 50 per cent of the estimated total Soviet uranium production in 1954. Uranium mining operations in eastern Germany were begun by the Soviets in October 1946. At first, they were confined to the Erzgebirge, in Saxony, around the towns of Johanngeorgenstadt, Oberschlema, Niederschlema, Schneeberg, Aue, Annaberg, Marienberg, Schwarzenberg, Freiberg, and Dresden. The operations have continually expanded and in 1954 the area around Auerbach, Oelanitz, Bergen, and Schmiedeberg (East Germany) and Thuringia (near Gera, Ronnebourg, and Sorge Settendorf where large quantities of low-grade ore are mined. Prospecting operations have been conducted in all possible areas. Uranium of all qualities has been mined—a fairly large amount of high-grade ore and very great amounts of low-grade ore. The greatest portion of uranium shipped from Germany is in the form of so called high-grade ore with an average U-metal content of about 1.50 per cent (obtained by hand and machine sorting).

Based upon the present extent of operation, it is estimated that uranium production in Germany will continue at the present level for at least three or four more years before gradually declining.

(2) Operations—Soviet uranium mining operations in Germany are under the control of a Soviet-German company called "Wismut S. D. A. G.". Wismut, formed in June 1947, is headed by MVD Major General Alexei Matveyevich Bogatov. Subordinate units of Wismut are called "Objekts" and, as a rule, are organized for a specific purpose: some are mining combines controlling a number of mine shafts within a local area; some are mine development projects which build facilities, sink new shafts, extend drifts, etc.; some are concentrating plants; some are engaged in making machinery and tools.

Wismut has opened and developed approximately 400 shafts in Germany since operations began in 1946. The individual shafts, or mines, are too numerous to list in this text, but the main mining objects are as follows:

"Objekt"	Headquarters
1	Johanngeorgenstadt
2	Oberschlema
6	Auerbach
7	Bärenstein
9	Aue
90	Gera
96	Dresden

Wismut has mined solely for uranium. Until recently, there was no attempt made to utilize the silver, cobalt, bismuth, nickel, and other ores which were mined along with uranium ore; these other ores were all thrown on huge waste piles.

Mining methods which are fairly standard for working hard rock vein-type deposits are used by Wismut. Some of the ore is suitable for direct shipment to the USSR, but a great deal of the materials is of such low grade that this is impracticable. This latter material must be concentrated to a grade of at least 1 per cent or more uranium metal before being shipped. Wismut has, at present, eight concentrating plants which process low-grade ore. These plants are: Object 31, and Langenfeld; Object 32, at Tannenbergsthal; Factory 95 of Object 96, at Gittersee/Dresden; Factory 96 of Object 96, at Freital/Dresden; Object 98, at Johanngeorgenstadt; Factory 99 of Object 2, at Oberschlema; Object 100, at Aue; and Object 101, at Zwickau/Crossen.

About 150,000 workers are employed by Wismut; at least 90 per cent of them Germans. Because production has increased steadily through the years, it is believed that Wismut is currently producing at its peak. Production will probably continue at the present level for the next three or four years before declining slowly.

c. Czechoslovakian Sources

(1) Ore deposits—The uranium deposits in Czechoslovakia are important source of Soviet uranium. The present output is about 10 per cent of the total estimated production by the USSR in 1954. Unlike East Germany and the other Satellites, mining and supervision is performed by the Czechs. The Soviets are continuing to make great efforts to increase this output and have initiated extensive prospecting and development programs. Prospecting operations have extended throughout Czechoslovakia.

The Soviets took over the uranium mines in Czechoslovakia before September 1945. At that time, a secret agreement was made between the Soviet Government and the Czech Prime Minister Fierlinger whereby the Soviet Government would supervise the exploitation of the Bohemian uranium mines and take the entire output, returning to Czechoslovakia part or all of the recovered radium. Operations were started in the old uranium mines of Jachymov, located on the Czech side of the Erzgebirge. The exploitation was soon extended to the surrounding area and now includes the towns of Vejprty, Abertamy, Potucky, Seify, Bozi Dar, Dürnberg, Maria Sorg, Werlsgrün, and many more. As a result of very intensive exploration programs, new uranium mining areas at Pribram, Horni-Slavkov, Marianske Lazne, Drmoul, Trutnov, and a number of smaller areas have been opened up in Czechoslovakia.

(2) Operations–The uranium mining operations in Czechoslovakia are directly under the control of "The Jachymov Mines National Corporation". That organization, at least at the higher levels, is jointly administered. The Soviets, however, have virtually complete control of the corporation as most of the Czech officials were chosen on a basis of their cooperation with the USSR and communist

party membership. The individual mining areas are under the control of separate enterprises called "Inspectorates". The following are the known Inspectorates with their area of operation:

Inspectorates I and II are located in the area around Jachymov. These are the second most important producer. The principal mines in Inspectorates I and II are the Bratrstvi, Rovnost 1 and 2, Svornost, Joseph, Elias 1 and 2, Marianska, Eduard, Bohumil, Barbara, Eva, and Klavno.

Inspectorate VI is located at Horni Slavkov. At present, this Inspectorate is the largest producer in Czechoslovakia. The principal mines in this inspectorate are Prokop, Barbora, Svatopluk, Lesnice, Zdar Buh, Mines 9, 10, 11, 12, 14, 15, 16, 18, and 19.

Inspectorate K-2 is located at Pribram. It produced a small amount of ore.

The Inspectorate X at Trutnov is still in production. Probably mostly low-grade material is handled here from sedimentary deposits.

Other inspectorates about which little is known and which are probably small producers are the Inspectorate at Marianske Lazne and the Inspectorate at Zvolen.

The method of mining and handling the ore in Czechoslovakia is nearly the same as in Germany. Much of the higher grade ore is sent to the Vykmanov and Njedek collection and shipping depot where it is crushed, sampled, blended, and packed for shipment to the USSR. The low-grade ore is sent to concentrating plants located at the Bratrstvi and the Elias mines in Jachymov. All these plants utilize a mechanical concentration method only. At the present time, there appears to be no chemical concentration plant in operation by the Jachymov Mines National Corporation. The mechanical processing method used is similar to that followed by Wismut. The grade of the concentrate is between 1 and 2 per cent uranium metal. As development and production increase, other concentrating plants may be established in the Norni Slavkov and Pribram areas.

It is estimated that between 15,000 and 25,000 persons are engaged in uranium mining operations in Czechoslovakia. A significant portion of the laborers are Czech political prisoners.

d. Bulgarian sources

(1) Ore deposits—The uranium deposits in Bulgaria are of minor importance and, in 1954, produced approximately 5 per cent of the estimated total uranium obtained by the USSR in that year. The deposits being exploited at this time are composed mostly of secondary uranium minerals which occur mainly as thin coatings along fissures or are disseminated throughout brecciated zones. A certain amount of deep mining may now be taking place from the primary minerals.

The most important uranium deposit in Bulgaria is located in the old lead mining area of Goten Peak, near the monastery of Buhovo, northeast of Sofia. In late 1945, the Soviets continued the former German exploitation of this area. Later exploitation of other areas, such as those in the vicinity of Strelcha and Ihtiman, was begun. Prospecting operations and mining are also underway at a number of other locations.

(2) Operations—The uranium mining operations in Bulgaria are administered by the Soviet-Bulgarian Mining Company. Most of the ore now being produced is low grade and is concentrated before being shipped to the USSR. There is only one well-known ore concentrating plant in Bulgaria which is located at the site of the Buhovo mine. The ore is chemically concentrated, using an acid lead. Some of the ore is reported to be hand-sorted and does not require further concentration before being sent to the USSR, but it is believed that most of it is quite low grade and is first concentrated by the Buhovo plant. The concentrate produced probably contains over 1 per cent

uranium. It is estimated that between 6,000 and 10,000 persons are engaged in uranium mining operations in Bulgaria.

e. Polish Sources

(1) Ore deposits—The uranium deposits in Lower Silesia in Poland are of minor importance as a Soviet source of uranium, and constituted approximately 1 per cent of the total produced by the Soviets in 1954.

Soviet uranium mining operations were initiated in Poland in April 1947, but intensive development did not really begin until early 1948. The initial development was in the Kowary area (the old Schmiedeberg area exploited by the Germans) where uranium was produced before the war, and activities have spread to areas around Jelena Gora (Hirschberg), Miedzianka (Kupferberg), Kamienna Gora (Landeshut), Walbrzch (Waldenburg), Stronie Slaskie (Seitenberg), etc. Exploration is also underway in other areas, but Kowary still seems to be the main producing area.

The uranium deposits in Poland are small fissure veins consisting, in some cases, of martitic iron ore with associated pitchblende. Other veins contain barite and dolomite with some uranium minerals. The extent of the mineralization appears to be somewhat limited but the thoroughness with which the Soviets exploit the deposits, regardless of cost, may produce a small quantity for several years. The quality of the ore produced is not definitely known but is assumed to be the same as that produced in East Germany.

(2) Operations—The Soviet uranium mining operations in Poland are similar to those in East Germany. Concentrating plants are believed to be operating at Miedzianka and Ogorzelec (Dittersbach). The type of process used in these plants is not definitely known, although it is reported that the plant near Ogorzelec uses a mechanical separation process.

The uranium mining operations in Poland are administered by the Lower Silesian Mines, Kowary. This is believed to be a cover organization similar to Wismut, in East Germany, on a much smaller scale. It is estimated that from 6,000 to 10,000 workers are engaged in the uranium mining activities in Poland.

f. Romanian Sources

(1) Ore deposits—The uranium deposits of Romania constitute approximately 2 per cent of the total produced by the Soviets in 1954.

Soviet uranium mining operations were initiated in Romania in late 1952. Mining is presently being carried out in the Baia de Cris/W to Baita region and probably also at Baia Sprie, Baia Mare, Turnu Severin and the Galati areas.

The uranium deposits in Romania are small fissure veins of polymetallic minerals with associated pitchblende. The quality of the ore produced is not known. Probably some of it is hand sorted to a minimum grade of 1 or 2 per cent uranium before being shipped to the USSR.

(2) Operations—The Soviet uranium mining operations in Romania are probably similar to those in other satellite countries, although no information is available on the existence of any concentration plants.

The uranium mining operations in Romania are administered by the Sovrumquartz Company. This is believed to be a cover organization similar to Wismut, in East Germany. It is estimated that some 10,000 workers are engaged in the uranium mining activities in Romania.

Alwin Urff, deputy technical plant manager of the Asse nuclear disposal site in Germany. Hasso Ziegler. Die "Konzertsäle" von Asse sind strahlensicher: Endlagerung radioaktiver Abfallprodukte in 500-Meter tiefen Abbaukammern. *Hannoversche Allgemeine Zeitung.* 29 July 1974.

Wolfenbüttel.—Zehn starke Scheinwerfer tauchen das Betriebsgelände des vor zehn Jahren stillgelegten Salzbergwerks Asse bei Wolfenbüttel—rund acht Kilometer vor der Grenze zur DDR gelegen—des Nachts in taghelles Licht. Die Polizei fährt das abgelegene Bergwerk zwei- bis dreimal pro Nacht an und kontrolliert, ob es besondere Vorkommnisse gibt. Außerdem steht eine telefonische Direktleitung zur Polizei Wolfenbüttel zur Verfügung, um sofort Alarm schlagen zu können. Die Sicherheitsvorkehrungen dienen dem Schutz vor der "verbannten Materie", wie die volkstümliche Umschreibung für die radioaktiven Abfälle lautet, die—zentral für die ganze Bundesrepublik—seit 1967 in dem ehemaligen Salzbergwerk in Tiefen bis zu 750 Metern als "Endlagerung" deponiert werden. [...]

Das ehemalige Salzbergwerk Asse bot im übrigen, als es 1965 von der Bundesregierung für 750 000 Mark von den vorherigen Eigentümern gekauft wurde, ideale Voraussetzungen, um die radioaktiven Abfälle aus der ganzen Bundesrepublik für die nächsten Jahrzehnte deponieren zu können. Von 1908 bis zu seiner Stillegung 1964 waren rund vier Millionen Kubikmeter Salz abgebaut worden, die wiederum rund 130 leergebliebene Abbaukammern hinterließen—in der Größe von durchweg 60 Metern Länge, 40 Metern Breite und 15 Metern Höhe. Knapp die Hälfte dieser leeren, weißglitzernden "Konzertsäle" gelten als geeignet für die Einlagerung radioaktiver Abfälle, ein Volumen mithin von 1,5 Millionen Kubikmetern—genug für Jahrzehnte. [...]

Wolfenbüttel.—Ten powerful headlights illuminate the site of the Asse salt mine near Wolfenbüttel, which was shut down ten years ago, and is located about eight kilometers from the border of East Germany. The police drive to the remote mine two or three times a night and check whether there are any unusual occurrences. In addition, a direct telephone line to the Wolfenbüttel police is available, to be able to respond immediately. The precautionary measures are designed to protect against the "banished matter," as is the national description of radioactive waste, for which the former salt mine at depths up to 750 meters has been the central "final disposal" for the whole of West Germany since 1967. [...]

The former Salzberg mine Asse, when bought in 1965 by the federal government for 750,000 Deutschmarks from the previous owners, was the ideal requirement for the disposal of radioactive waste from all of West Germany for the next decades. Between 1908 and its closure in 1964, around four million cubic meters of salt had been mined, which in turn left behind around 130 empty mining chambers—in the size of 60 meters long, 40 meters wide, and 15 meters high. Just half of these empty white glittering concert halls are considered suitable for the storage of radioactive waste, a volume of 1.5 million cubic meters—enough for decades. [...]

Für die hochaktiven Abfälle schließlich, die frühestens ab 1976 in der Bundesrepublik anfallen und dann in Asse eingelagert werden sollen (vornehmlich die Rückstände aus wiederaufbereiten Spaltprodukten, zum Beispiel Brennstäbe), laufen noch umfangreiche Vorarbeiten. Es ist daran gedacht, sie—zuvor zu Glas verschmolzen—in Spezialkammern (Bohrlöcher) in fünfzehnhundert Meter Tiefe zu versenken.

Über die gelegentlich auftauchenden Hiobsbotschaften befragt, die dann und wann über die vermeintlich gefährliche Lagerung der radioaktiven Abfälle auftauchen, konnte Alwin Urff, Bergingenieur und stellvertretender Betriebsleiter in Asse, im übrigen nur den Kopf schütteln: “Hier im Berg kann jedenfalls nichts mehr passieren. Als wir 1967 mit der Einlagerung begannen, hat unsere Gesellschaft als erstes radioaktive Abfälle aus dem letzten Krieg versenkt, jene Uranabfälle, die bei der Vorbereitung der deutschen Atombombe anfielen. Die mußten wir nämlich aus Betonbunkern in der Nähe von München herausholen, wo sie seinerzeit deponiert worden waren, weil man damals ja nicht wußte, wo in drei Teufels Namen man das Zeug denn lassen sollte...”

Extensive preparatory work is still going on for the highly radioactive waste, which will accumulate at the earliest from 1976 onwards in West Germany and be stored in Asse (mainly the residues from reprocessed fission products, for example reactor fuel rods). It is thought to sink them—vitrified beforehand—in special chambers (drill holes) to a depth of fifteen hundred meters.

Asked about the occasional bad news that appears every now and then regarding the supposedly dangerous storage of radioactive waste, Alwin Urff, mining engineer and deputy technical plant manager in Asse, only shook his head: “Here in the mine nothing can happen anyway. When we began storage in 1967, our company first sank radioactive waste from the last war, that uranium waste which arose in the preparation of the German atomic bomb. Specifically we had to get that out of concrete bunkers near Munich, where it had been deposited at the time, because back then one did not know where the devil one should leave the stuff...”

Rainer Karlsch. 2013. Die Abteilung Atomphysik der PTR in Ronneburg und das deutsche Uranprojekt. *PTB-Mitteilungen* 123:1:73–81.

Den Fassbegleitkarten dieser ersten, versuchsweisen Einlagerung radioaktiver Abfälle in der Schachtanlage Asse II—die vom 4. April bis zum 4. Juli 1967 dauerte und zur Einlagerung von 1722 Fässern in die Kammer 4 auf der 750-m-Sohle führte—ist lediglich zu entnehmen, dass sämtliche Fässer aus Karlsruhe kamen [57].

[57] Mitteilung von Dr. Gernot Eilers vom Bundesministerium für Umwelt, Naturschutz und Reaktorsicherheit, 8.1.2013

From the identification cards accompanying this first experimental emplacement of radioactive waste in the Asse II mine—which lasted from 4 April to 4 July 1967 and led to the emplacement of 1722 drums in chamber 4 on the 750 m level—it can only be inferred that all the drums came from Karlsruhe [57].

[57] Communication from Dr. Gernot Eilers of the Federal Ministry for the Environment, Nature Conservation, and Nuclear Safety, 8 January 2013

[As evidence that dangerous radioactive waste could be safely stored in the salt mine, Alwin Urff said that the “radioactive uranium waste” from the “preparation of the German atomic bomb” during the war had been safely stored since 1967. He seemed to be in a position to have detailed and accurate knowledge about that waste, and his statement included several key points:

- Urff’s statement appears to demonstrate that there was a considerable amount of wartime radioactive uranium waste, since it filled multiple concrete bunkers before it was moved to Asse. (What was the actual location of the storage bunkers?) According to Asse’s own records, that particular batch of waste fills 1722 drums.

- Urff’s statement also seems to indicate that the wartime waste was quite radioactive, since he was using it as an example that strongly radioactive modern waste could also be safely stored at Asse. He explicitly called the waste both “radioactive” and “uranium waste.”

- Urff’s statement appears to indicate that all of that particular batch of atomic bomb waste was stored at Asse, which lends strength to his argument about the safety of storage at Asse, and also corresponds to the 1967 date that radioactive waste storage began at Asse. Nonetheless, there is the possibility that he simply meant that his company safely “sank” the bomb waste someplace in 1967, not necessarily all at Asse. Some nuclear waste was even disposed of at sea in the 1960s.

- Contrary to how Urff’s quote was interpreted by many later articles, he did not say that all of the nuclear waste stored in the Asse complex came from the war. 1722 barrels were deposited in April–July 1967, and postwar radioactive waste has been deposited ever since. Erroneously and without any foundation, some later articles attributed over 126,000 barrels of radioactive waste in Asse to the wartime program [e.g., https://www.dailymail.co.uk/news/article-2014146/Nazi-nuclear-waste-Hitlers-secret-A-bomb-programme-mine.html].

Was the waste from a bomb program, or merely a nuclear research program? Large amounts of uranium in various chemical states from the research program were found at locations around Germany and removed by the United States, United Kingdom, and Soviet Union. Why was it so important to bury this particular “radioactive uranium waste”? The waste could have been any (or some combination) of the following:

- Natural (unenriched) uranium in common wartime forms, such as uranium ore, uranium oxide, or uranium metal. That would not be any more radioactive than natural uranium ore from the ground, or any different from all of the uranium materials that were left for Allied forces to find. Moreover, it would be potentially useful material for the postwar nuclear program and not technically waste. Thus this possibility does not seem very likely. However, it may have been desired to simply get rid of any remaining uranium from wartime work, no matter how relatively benign the uranium and the work may have been.

- Chemically toxic and/or corrosive compounds of uranium, such as uranium hexafluoride. But significant quantities of such compounds were stored and found elsewhere in Germany. Why was this waste handled differently, if that is all it was?

- Depleted uranium from which ^{235}U has been extracted. That would be no more radioactive that natural uranium, which was freely stockpiled at Stassfurt and elsewhere without such special handling, and would not seem to serve Urff's example that the wartime waste was quite radioactive and yet had been safely "sunk." On the other hand, if the waste were depleted uranium, that would reveal how much enriched uranium had been produced, and it might have been desirable to hide that evidence in order to cover up the traces of an advanced nuclear program.

- Irradiated uranium that had been in a functioning fission reactor or electronuclear breeder. Such irradiated uranium would have been highly radioactive early on, although that radioactivity would fall off over time. Irradiated uranium would best fit the example that Urff was trying to make, although it may or may not have been what he was actually referring to.

- ^{233}U, ^{235}U (enriched to any degree), ^{237}Np, or ^{239}Pu that was produced but buried to cover up evidence of an advanced nuclear program.

How did Urff know that was indeed "radioactive uranium waste" from the "preparation of the German atomic bomb" during the war? What did he (and others at Asse) do during the war?

In 2013, paragraph 57b of the German Atomic Energy Act was amended to the effect that the radioactive waste stored in the Asse II mine must be retrieved before the mine is decommissioned. The current timetable assumes that retrieval will begin in 2033. Before being prepared for interim and final storage elsewhere, all waste must be examined in order to characterize its composition. If the wartime waste can be distinguished from the later waste, what will be learned from it?]

D.4 Enrichment of Uranium-235

[Only 0.72% of natural uranium is ^{235}U, the fissile isotope. In order to achieve high concentrations of ^{235}U for a fission bomb, it is necessary to enrich or separate ^{235}U from the other uranium isotopes. Currently available documents demonstrate that during the war, Germany developed several different methods of enrichment at least to the level of successful laboratory prototypes, and quite possibly on a large industrial scale:

D.4.1. Production of uranium hexafluoride for uranium-235 enrichment. I.G. Farben and other German-speaking research facilities developed, tested, and mass-produced uranium hexafluoride (UF_6), the preferred uranium compound for use in most enrichment approaches (p. 3478).

D.4.2. Uranium-235 enrichment via centrifugation. Konrad Beyerle (German, 1900–1979), Wilhelm Groth (German, 1904–1977), Werner Holtz (German, 1908–?), Werner Schwietzke (German, 1910–1987), and many others worked in teams that developed gas centrifuges to enrich uranium-235. Centrifugation proved so superior to the U.S.'s enrichment methods that the German gas centrifuge designs are now the worldwide standard for uranium enrichment (p. 3494).

D.4.3. Uranium-235 enrichment via electromagnetic separation. Manfred von Ardenne (German, 1907–1997), Heinz Ewald (German, 1914–1992), Wolfgang Paul (German, 1913–1993), Wilhelm Walcher (German, 1910–2005), and many others worked in teams that developed electromagnetic separators to enrich ^{235}U (p. 3554). These electromagnetic separators were comparable to the Manhattan Project's calutrons. Manfred von Ardenne's work was well funded during the war, and he became a central figure in the Soviet nuclear weapons program after the war.

D.4.4. Uranium-235 enrichment via gaseous diffusion. Gustav Hertz (German, 1887–1975), Erika Cremer (German, 1900–1996), Rudolf Fleischmann (German, 1903–2002), and others developed gaseous diffusion methods suitable for enriching ^{235}U that were comparable to the Manhattan Project's gaseous diffusion technology (p. 3618). Hertz's secret wartime work was deemed so important by the German government that he was allowed to live and work in relative comfort throughout the war despite his Jewish ancestry. After the war, he played a vital role in the Soviet nuclear weapons program. Erich Bagge (German, 1912–1996) invented and successfully demonstrated a unique uranium enrichment device called an isotope sluice, which was essentially an alternative method of gaseous diffusion separation (p. 3651).

D.4.5. Uranium-235 enrichment via photochemical processes. Stanisław Mrozowski (Polish, 1902–1999), K. Zuber (Swiss, 19??–19??), Werner Kuhn, Hans Martin, K. H. Eldau, Paul Harteck, and others developed photochemical methods of isotope separation, demonstrated them with elements such as mercury, and worked to apply them to uranium (p. 3664). It is currently unclear how far that work progressed during the war, but it became the basis of postwar laser isotope separation. (Section C.3 covers early work toward lasers in the German-speaking world).

D.4.6. Possible locations of uranium enrichment facilities. If Germany scaled up any of these proven enrichment methods in order to produce uranium-235 for nuclear weapons, it would have distributed that production capability among a number of small underground locations for protection against Allied bombing. The leading industrialist Adolf Schneider actually confirmed in 1944 that Germany was doing precisely that (p. 4400). Archival documents mention dozens of highly suspicious sites that might have been used for that purpose and that still have not been properly investigated (p. 3670).]

D.4.1 Production of Uranium Hexafluoride for Uranium-235 Enrichment

[Usually uranium is converted into the gaseous compound uranium hexafluoride (UF_6) for enrichment. (Uranium tetrachloride, UCl_4, is generally preferred for electromagnetic separation.) UF_6 is highly corrosive to most materials except nickel. German reports captured by the U.S. Alsos Mission demonstrate that at least as early as 1940, the German program was fully aware of this information and capable of producing UF_6, and that much of that production capability was at I.G. Farben. Unless otherwise noted, text for G-series captured German nuclear reports cited here consists of the English-language abstracts prepared by U.S. scientists who studied the German reports.]

G-32. Wilhelm Groth and Paul Harteck. Corrosion Experiments on Two Alloys (Steel and Light Metal Alloys) with UF_6. 12 May 1940. [See p. 3480.]

Investigations were undertaken in a quartz vessel with very pure UF_6. 10 grams of UF_6 was sublimed into the vessel and the samples were exposed for 14 hours at 100^oC. [...] Same test setup but at 350^oC. [...] Corrosion of steel is excessive. Light metal, however, can be used in installations operating below 250^oC. For high temperature use nickel is the only suitable material.

G-33. Wilhelm Groth and Paul Harteck. Status of Work on Separating ^{235}U und ^{238}U. Stand der Arbeiten zur Trennung der Isotope ^{235}U und ^{238}U. 1940. [See pp. 3481–3483.]

Corrosion tests were made with UF_6 at 100 and 150^oC on monel, nickel, brass, copper, aluminum, silver, iron, and various commercial alloys. Results tabulated. Nickel only material suitable for high temperature use. On the basis of tests made with xenon the U isotopes can quite probably be separated by thermal diffusion using a double jacketed tube with a separating length of 10 m.

Developed method for checking concentration of ^{235}U. When ^{235}U is enriched, ^{234}U is also enriched. The alpha emission of ^{234}U is therefore a measure of ^{235}U concentration.

FIAT 1171. ***An Instrument for the Measurement of the Radio-Active Content of Moving Gases.***

G-28. Rudolf Fleischmann. Some Constants and Properties of UF_6. Ueber einige Konstanten und Eigenschaften von UF_6. 1940. [See pp. 3484–3487.]

UF_6, the only U compound which is gaseous at room temperature, is of essential importance for isotope separation. Unfortunately there is no complete theory of the separation process, from which the separation can be calculated from measurable constants of the substance to be separated. The theories of Waldmann and of Furry, Jones, and Onsager deal with the plane case but are qualitatively applicable to the cylindrical case. They permit the calculation of the proper size of the apparatus, when a few constants of the gas employed in the separation are known, particularly the coefficient of viscosity η, the density ρ, and the vapor pressure p as a function of the temperature. [These quantities were measured and reported.] Investigations with UF_6 are complicated by its affinity for water and its corrosive properties, but operation of a small experimental system shows that separation can probably be carried out nevertheless.

G-157. Paul Harteck and Wilhelm Groth (Institut für Phys. Chemie, Hamburg); Erich Noack and Walter Kwasnik (I.G. Farben Leverkusen). Herstellung von Uranhexafluorid im Halbtechnischen Masstab. Untersuchung der Legierungsfähigkeit von metallischem Uran. 11 June 1942. [See pp. 3488–3489.]

Description of usual laboratory method of making UF_6 from metallic U using Cl as catalyst. Kwasnik developed process whereby uranium oxide is carried through a rotating inclined nickel tube heated to 650^{o}C through which a stream of fluorine gas is passed. The UF_6 thus formed is frozen by CO_2 in containers. About 500 grams UF_6 thus produced per hour. The UF_6 to be frozen in large crystalline block to reduce amount of adsorption of other gases. Method of transport and handling of UF_6. Projected improvements of Kwasnik process. Possibility of using U ores directly instead of first purifying U. Costs 22–51 RM/kg. Experiments planned with U alloys of nickel, silicon, and chromium.

WO-21589

Korrosionsversuche an zwei eingesandten Metallegierungen (Stahllegierung und Leichtmetallegierung) mit Uranhexafluorid.

Die früheren Korrosionsversuche wurden im anorganischen Laboratorium der I.G.Farben in Leverkusen von Dr.Noack und seinen Mitarbeitern ausgeführt.
Für die jetzigen Korrosionsversuche an den uns übersandten Metallproben,denen wir als Vergleichsmetall Reinnickel zufügten,wurde in Hamburg eine Apparatur entwickelt,die die Korrosionsversuche unter Verwendung von Bodensteinschen Membranventilen aus Nickel unter völlig sauberen Bedingungen ohne Hähne,Schliffverbindungen oder anderen störenden Dichtungsmitteln ermöglichten.
Die verwendete Apparatur ist schematisch auf der beigefügten Zeichnung dargestellt.
Das Uranhexafluorid,das uns von Herrn Dr. Noack geliefert und bis zur Verwendung bei einer Temperatur von - 78°C bewahrt wurde,befindet sich in dem Gefäss A aus Quarz,das mit einem Zerschlageventil versehen ist.Als Zerschlagekörper wurde ein in Quarz vollkommen eingeschlossenes Eisenstück verwendet,das magnetisch betätigt werden konnte.An der Stelle B konnte das Quarzgefäss A abgeschmolzen werden,nachdem das Hexafluorid in die eigentliche Apparatur sublimiert worden war.Dies bestand aus zwei Quarzausfriergefässen C und D, einem Bodensteinschen Quarzspiralmanometer E,dem Bodensteinschen Membranventil aus Nickel F,das mit Hilfe eines aussen gedichteten Schliffes mit der Quarzapparatur verbunden war und dem Korrosionsgefäss G aus reinem Nickel von etwa 1,5 lt Inhalt.Nachdem die ganze Apparatur sorgfältig evakuiert war, konnte sie von der Pumpleitung an der Stelle H abgeschmolzen werden.

- 2 -

Die Sublimation des Uranhexafluorids in die Apparatur gestaltete sich sehr einfach,da der Stoff bei 0°C einen Dampfdruck von etwa 25 mm Hg hat,während die Temperatur eines Kältebades von - 78°C(Kohlensäure - Aceton) oder - 183°C (flüssiger Sauerstoff) der Dampfdruck praktisch null ist. -

Das Hexafluorid,das über meherere Monate aufbewahrt worden war und gelegentlich kürzere Zeit auch Zimmertemperatur angenommen hatte,bestand dennoch im Wesentlichen aus sehr reinen weissen Kristallen.Mit Hilfe der beiden Ausfriergefässe C und D unter dauernder Kontrolle durch das Spiralmanometer, wurde eine mehrmalige Umsublimation vorgenommen,wodurch eine völlige Reinigung von den letzten Spuren von Verunreinigung erzielt wurde.Es ist bemerkenswert,dass das Uranhexafluorid, sobald es mit Glas oder etwas Hahnfett in Berührung kommt, sich ausserordentlich stark zersetzt.Ausserdem wurde festgestellt,dass nach den Korrosionsversuchen das wieder in ein Ausfriergefäss sublimierte Hexafluorid,das nun Spuren von Zersetzungsprodukten enthielt,auch das Quarz angriff,sodass dieses oberflächlich abblätterte.
Die ersten Korrosionsversuche wurden bei einer Temperatur von etwa 100°C ausgeführt,nachdem eine Menge von etwa 10 g Hexafluorid,entsprechend etwa 700 ccm von Atmosphärendruck bei 0°C , in das Korrosionsgefäss sublimiert worden und das Membranventil geschlossen worden war.Das Ergebnis dieses Versuches,dessen Dauer 14 Stunden betrug,zeigt die Tabelle I.

Tabelle I

Leicht	Gewicht vor Vers.	Gewicht nach Vers.	Differenz	Differenz bezogen aus 10cm² Oberfläche (Vergleichswerte mit d.früheren Korros. Vers.)
Leichtmetall	3.252_5 g	$3,253_7$ g	$0,001_2$	
Stahl	$10,535_5$ "	$10,538_0$ "	$0,002_5$	
Nickel(z.Vergl.)	$2,514_5$ "	$2,514_5$ "	0	

Die Oberfläche der untersuchten Metalle betrug etwa 10 cm² .
Ein weiterer Versuch wurde bei etwa 350°C gemacht.Zu diesem Zweck wurde unter dem Korrosionsgefäss eine Asbestpappe und eine Messingplatte angebracht und das ganze Gefäss in Schlakkenwolle eingehüllt.Die Heizung erfolgte ~~duch~~ durch zwei starke

- 3 -

Bunsenbrenner;die Temperatur wurde mit einem kleinen,eng an der Oberfläche anliegenden Quecksilberthermometer etwas oberhalb der unteren Grundfläche gemessen.Um das Membranventil, dessen Membrane auf den Nickelkörper warm aufgesetzt und dann von aussen weich verlötet war,vor der hohen Temperatur zu schützen,war zwischen diesem und dem Korrosionsgefäss eine Kupferspirale angelötet,durch die Wasser geleitet wurde,sodass die Temperatur des Ventiles unter 70°C liegt.Dieser Versuch,der ebenfalls 14 Stunden dauerte,hatte folgendes Ergebnis:

Tabelle II

	Gewicht vor Vers.	Gewicht nach Vers.	Differenz	Differenz bezogen aus 10cm² Oberfläche (Vergleichswerte mit den früheren Korrosionsversuchen)
Leichtmetall	$3,253_7$	$3,280_4$	$0,026_7$	
Stahl	$10,538_0$	$10,570_1$	$0,032_1 (0,079_5)$	
Nickel (z.Vergl.)	$2,514_5$	$2,521_5$	$0,017_0$	

Während das Aussehen des Nickels und der Leichtmetallegierung nach dem ersten Versuch unverändert war,zeigten alle drei Metalle nach dem Versuch bei hoher Temperatur einen Beschlag. Dieser war beim Nickel am geringsten und vollkommen gleichmässig über die gesamte Oberfläche verteilt.Auch die Leichtmetallegierung war von einem dünnen gleichmässigen Belag bedeckt.Diese beiden Belege liessen sich durch trockenes Abwischen nicht entfernen.Der Stahl dagegen war sehr stark angegriffen,sodass das gebildete Metallsalz teilweise abfiel. Dieses Salz wurde besonders gewogen.Der beim Stahl in Klammern hinzugefügte Wert der Gewichtsdifferenzen vor und nach dem Versuch,ist die Summe der Zunahme der Probe selbst und des abgefallenen Salzes.Sowohl das Leixhtmetall als auch das Nikkel wurden nach der Wägung mit trockenem Filtrierpapier gereinigt,ohne dass dadurch eine Gewichtsänderung eintrat.
Es ist auffällig,dass die Korrosion des Stahles an einem Ende stärker ist als am anderen.Dieser Teil befand sich während

- 4 -

des Versuches in der Nähe des Gefässbodens,wo die Temperatur naturgemäss höher war als am oberen Ende;sie betrug hier wahrscheinlich megr als 350°C.
Zusammenfassend ist zu sagen,dass,wie schon die früheren Versuche zeigten,das Nickel weitaus am beständigsten gegen Uranhexafluorid ist und für Versuche bei höheren Temperaturen allein in Betracht kommt.Das Leichtmetall wird bei der hohen Temperatur um ein Mehrfaches stärker angegriffen;bei etwa 100°C ist die Beständigkeit aber recht gut,sodass z.B.für Zu- und Ableitungen,durch die das Gas nur bei Zimmertemperatur strömt,auch dieses Metall verwendbar sein dürfte,wahrscheinlich sogar auch für Trennrohre ,falls man sich mit einer Heiztemperatur des Trennrohres von 250°C begnügt.Am schlechtesten eignet sich der Stahl,der wohl unter keinen Umständen in Betracht kommen dürfte.
Die Verwendbarkeit der eingesandten Metallproben ergibt sich aus einem Vergleich der jetzigen mit den früher ausgeführten Korrosionsversuchen an Nickel,Monel,V2A,V4A,Messing,Kupfer, Aluminium,Silber,Eisen.(Siehe unseren Bericht vom 5.Juni1940)
Es ist allerdings zu berücksichtigen,dass die Gewichtsdifferenzen von der Stärke der trockenen Reinigung der korrodierten Proben abhängt,wodurch z.B. im Falle des Nickels eine bessere Uebereinstimmung der beiden Versuchsergebnisse erzielt werden könnte.
Die untersuchten Proben sind beigefügt.

This document has been declassified by authority of issuing installation. Letter dated 6-1-50 Noted by

Stand der Arbeiten zur Trennung der Isotope ^{235}U und ^{238}U.

von W. Groth und P. Harteck in Hamburg.

WO-21590

Die Vorarbeiten zur Trennung der Uranisotope ^{235}U und ^{238}U sind in zwei Richtungen aufgenommen worden. Die eine betraf das Aufsuchen eines Stoffes, der vom Uranhexafluorid nur mässig angegriffen wird; das zweite Problem bestand in der weiteren Ausarbeitung des Trennrohrverfahrens von Clusius und Dickel für die speziellen Erfordernisse, die bei der Trennung der Uranisotope im gasförmigen Uranhexafluorid auftreten.

I. Korrosionsversuche.

Diese Frage wurde durch die freundliche Mitarbeit der I.G. Farben Industrie A.G., insbesondere der Herren Dr. Noack und Dr. Kwasnick gelöst. Es wurde das Verhalten der folgenden Metalle gegen Uranhexafluorid untersucht: Monel, Nickel, Silverin, V2A, V4A, Messing, Kupfer, Aluminium, Silber und Eisen. Die Oberfläche der untersuchten Proben betrug 10 cm². Die Korrosionsversuche wurden bei 100°C, 150°C und neuerdings auch bei 360°C durchgeführt, ohne dass mit steigender Temperatur eine wesentliche Korrosionszunahme festgestellt werden konnte. Die Ergebnisse der Versuche sind in den folgenden Tabellen dargestellt

~~SECRET~~ UNCLASSIFIED

~~SECRET~~

4.

Die Gewichtsänderungen sind so zustande gekommen, dass der schlechthaftende Belag, der sich in allen Fällen bei der Einwirkung des Hexafluorids auf Metallen bildet, entfernt wurde, sodass die Gewichtzunahme ein Mass für die Angreifbarkeit des Metalles durch Uranhexafluorid ist.

Von den untersuchten Metallen erwies sich das Nickel, vor allem in den Dauerversuchen über 7 Tage bei 360°C, der in Aussicht genommenen Versuchstemperatur, als allen Metallen weitaus überlegen. Es wird vom Uranhexafluorid oberflächlich leicht angegriffen. Dabei ensteht ein grüner, festhaftender Belag, der das Nickel vor weiterer Korrosion schützt. Es ist deshalb anzunehmen, dass reines Nickel auch bei Dauerversuchen beständig sein wird, sodass die Materialfrage für die Versuchsanordnung damit gelöst zu sein scheint.

Zwei Trennrohre aus reinem Nickel von 2m bzw. 8m Länge sind seit längerer Zeit in Auftrag gegeben, aber infolge der Schwierigkeit der Materialbeschaffung nach wie vor in Arbeit. Als Ein-und Auslassventile sind Bodensteinsche Membranventile aus reinem Nickel vorgesehen.

II. Ausarbeitung des Trennrohrverfahrens von Clusius und Dickel.

Trennrohrversuche sind, ausser von Clusius und Dickel[1], von Fleischmann in Heidelberg[2], in den Vereinigten Staaten[3] und von uns in Hamburg[4] durchgeführt worden. Für unsere Arbeitrichtung ist charakteristisch, dass wir als Analysenmethode zum Nachweis der Verschiebung des Isotopenverhältnisses die Wärmeleitfähigkeitsmethode entwickelt und so weit verfeinert haben, dass bei Proben von 1 cbcm von Atmosphärendruck eine Verschiebung des Atomgewichtes um 0,01 % leicht nachgewiesen werden kann.[4]

Wir benutzten im Zusammenhang mit den vorliegenden Aufgaben als Versuchsgas im wesentlichen Xenon. Das Xenon besitzt die fölgenden 9 Isotope: 124(0,094%), 126(0,088%), 128(1,91%), 129(26,23%), 130(4,06%), 131(21,18%), 132(26,98%), 134(10,55%), 136(8,95%), und kommt mit seinem mitleren Atomgewicht von 131,3 dem Uranhexafluorid (Atomgewicht 349 bzw. 352) relativ nahe. Die Erfahrungen dagegen, die von anderen Autoren und von uns an leichteren Gasen (Krypton, Metan, Stickstoff, Neon usw.) gemacht wurden, können nur unter grösseren Vorbehalten auf das Uranhexafluorid übertragen werden.

Zur Zeit sind für die Trennung in der Gasphase 2 Arten von Trennrohren in Verwendung. Die einen, wozu auch die ersten von Clusius und Dickel angegebenen gehören, besitzen einen in einem vertikalen Glasrohr zentrisch gespannten, elektrisch geheizten Draht, wobei das Glasrohr meistens aussen wassergekühlt wird. Der Durchmesser des Drahtes beträgt weniger $^{1}/10$mm, der des Glasrohres, je nach der veränderten Drahttemperatur und der Dichte des untersuchten Gases, zwischen 5 und 20 mm. Die zweite Art der Trennrohre besteht aus 2 konzentrischen Rohren aus Glas oder Metall, von denen das eine entweder durch einen axial ausgespannten Draht, durch eine Leuchtgasflamme oder – wie es bei unseren Versuchen, bei denen das innere Rohr geheizt wurde, der Fall war – durch den Dampf einer siedenden Flüssigkeit geheizt werden kann. Im letzten Fall ist eine weitgehende Temperaturkonstanz gewährleistet. Das Aussenrohr wurde bei unseren Versuchen teils luft-, teils wassergekühlt. Bei allen Tennrohren ist es bekanntlich günstig, in Abständen von 15 bis 20cm Strömungswiderstände einzubauen, die eine zu weite Ausbreitung von unerwünschten (turbulenten) Strömungsformen verhindern sollen.

~~SECRET~~

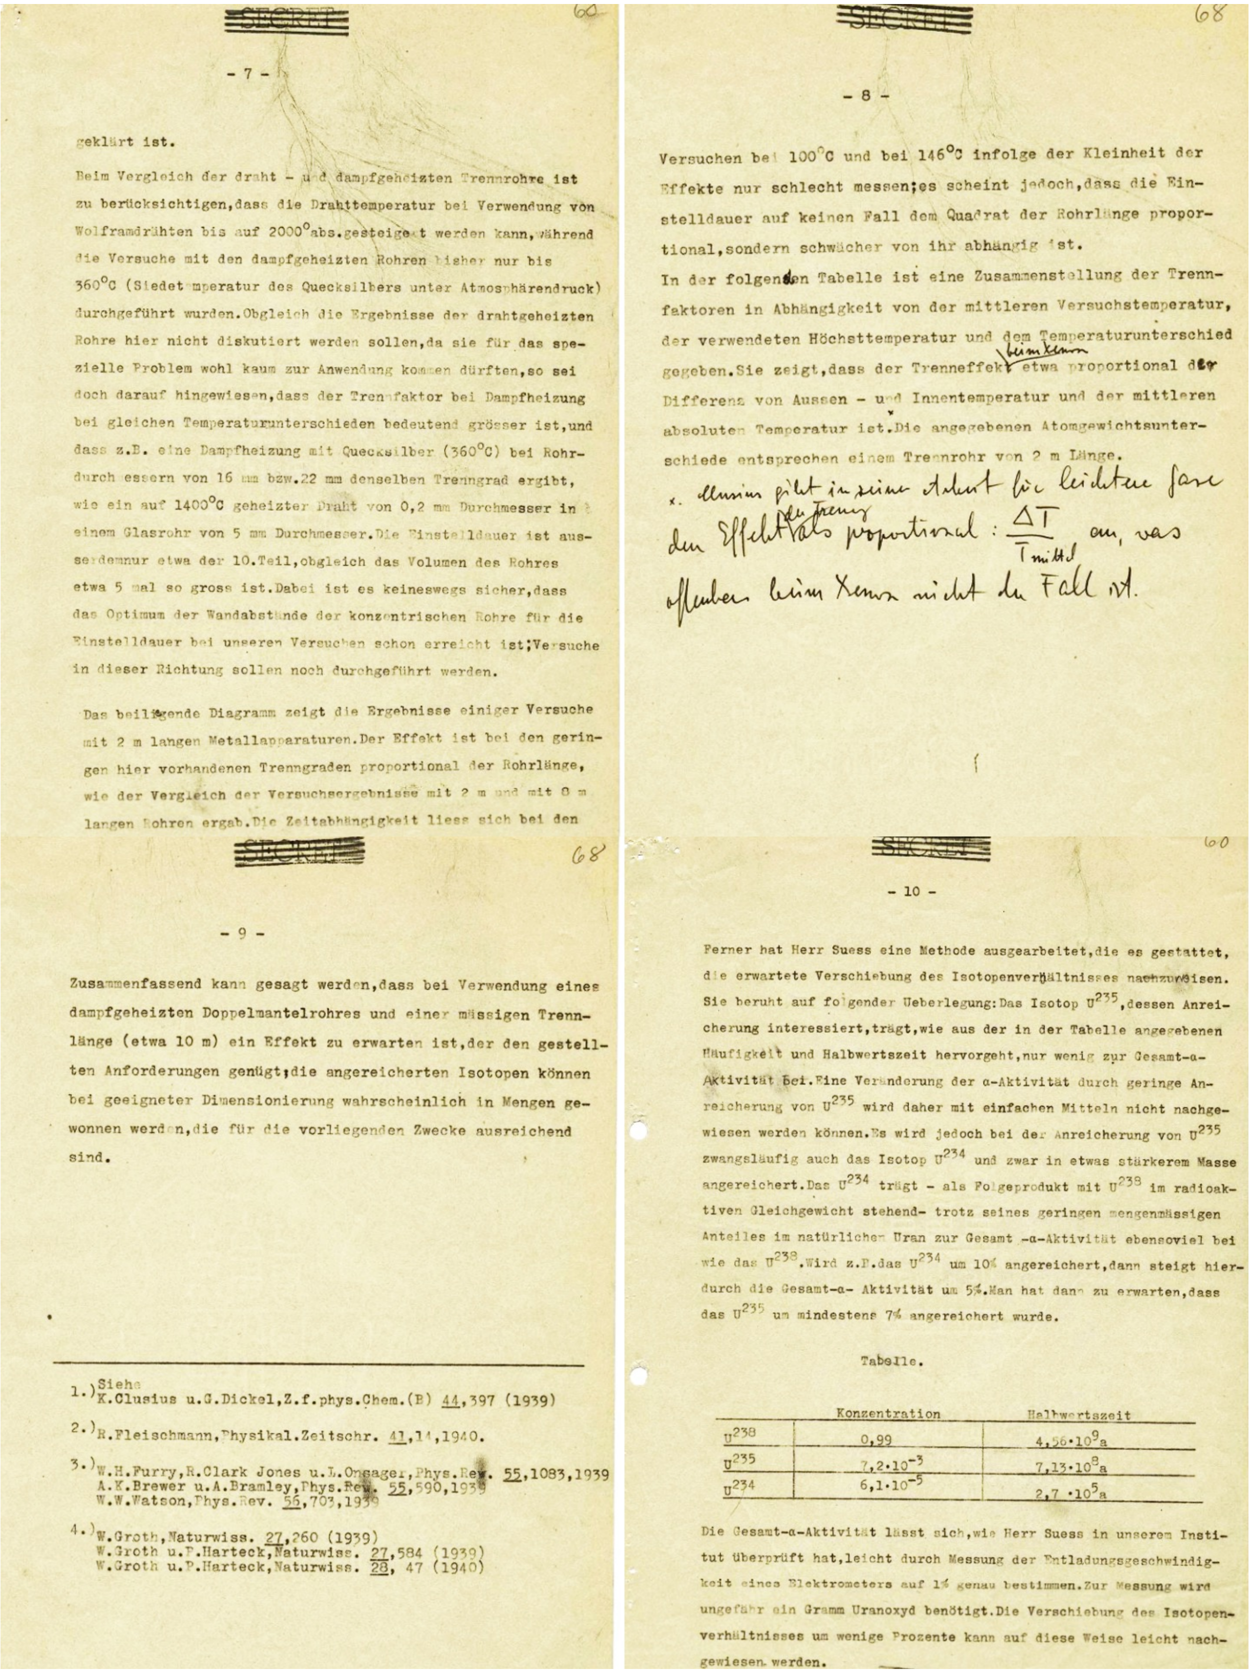
- 6 -

4) Unseren ersten Trennversuche führten wir mit zwei drahtgeheizten Anordnungen von 2 m und 5,5 m Länge aus. Die Drahtdurchmesser waren 0,2 mm, die Glasrohre hatten einen inneren Durchmesser von 5 mm. Wir gingen dann zu Trennrohren über, die aus zwei konzentrischen Glasröhren bestehen und verwendeten Apparaturen von 2 m und 8 m Länge. Der äussere Durchmesser der inneren Rohre betrug 17 mm, der lichte Durchmesser der äusseren Rohre 23 mm, sodass ein Wandabstand von 3 mm entstand, alle 15 cm wurden Glasscheibchen eingebaut, die gleichzeitig als Strömungswiderstände und zur Zentrierung der Rohre dienten. Die Heizung erfolgte in diesem Falle entweder mit Wasserdampf oder mit dem Dampf von siedendem Tetrachloräthan (Siedepunkt 146°C). Ausserdem haben wir eine Versuchsanordnung aus zwei konzentrischen Eisenrohren aufgestellt, deren Formen der bestellten Nickelapparatur gleicht. Die Höhe der Eisenapparatur beträgt allerdings nur 2 m, während die der endgültigen Nickelapparatur etwa 8 m betragen soll. (Eine Skizze der Eisenapparatur liegt bei.) Die Heizung erfolgte in diesem Falle durch den Dampf von siedendem Quecksilber (360°C). Das äussere Rohr wurde teils luftgekühlt, wobeo es sich auf etwa 130°C erwärmte, teils durch eine Wasserkühlung auf 20°C gehalten.

Die durchgeführten Versuche ermöglichen es, die einzelnen interessierenden Grössen, wie Wirkungsgrad, Trenndauer und getrennte Menge in Abhängigkeit von der Rohrlänge, dem Temperaturunterschied und der Art der Trennrohre (Draht- oder Dampfheizung) anzugeben.

Wir möchten vorwegnehmen, dass unsere Ergebnisse in einigen Punkten von denen von Clusius und Dickel abweichen, möchten jedoch darauf hinweisen, dass Neon und Xenon ein verschiedenes Verhalten zeigen, falls die Anziehungskräfte zwischen den Molekülen eine wesentliche Rolle spielen – eine Frage, die zur Zeit noch nicht

Figure D.123: Production and testing of uranium hexafluoride in 1940 [G-33].



~~SECRET~~

geklärt ist.

Beim Vergleich der draht - und dampfgeheizten Trennrohre ist zu berücksichtigen,dass die Drahttemperatur bei Verwendung von Wolframdrähten bis auf 2000°abs.gesteigert werden kann,während die Versuche mit den dampfgeheizten Rohren bisher nur bis 360°C (Siedetemperatur des Quecksilbers unter Atmosphärendruck) durchgeführt wurden.Obgleich die Ergebnisse der drahtgeheizten Rohre hier nicht diskutiert werden sollen,da sie für das spezielle Problem wohl kaum zur Anwendung kommen dürften,so sei doch darauf hingewiesen,dass der Trennfaktor bei Dampfheizung bei gleichen Temperaturunterschieden bedeutend grösser ist,und dass z.B. eine Dampfheizung mit Quecksilber (360°C) bei Rohrdurchmessern von 16 mm bzw.22 mm denselben Trenngrad ergibt, wie ein auf 1400°C geheizter Draht von 0,2 mm Durchmesser in einem Glasrohr von 5 mm Durchmesser.Die Einstelldauer ist ausserdemnur etwa der 10.Teil,obgleich das Volumen des Rohres etwa 5 mal so gross ist.Dabei ist es keineswegs sicher,dass das Optimum der Wandabstände der konzentrischen Rohre für die Einstelldauer bei unseren Versuchen schon erreicht ist;Versuche in dieser Richtung sollen noch durchgeführt werden.

Das beiliegende Diagramm zeigt die Ergebnisse einiger Versuche mit 2 m langen Metallapparaturen.Der Effekt ist bei den geringen hier vorhandenen Trenngraden proportional der Rohrlänge, wie der Vergleich der Versuchsergebnisse mit 2 m und mit 8 m langen Rohren ergab.Die Zeitabhängigkeit liess sich bei den

~~SECRET~~

Versuchen bei 100°C und bei 146°C infolge der Kleinheit der Effekte nur schlecht messen;es scheint jedoch,dass die Einstelldauer auf keinen Fall dem Quadrat der Rohrlänge proportional,sondern schwächer von ihr abhängig ist.

In der folgenden Tabelle ist eine Zusammenstellung der Trennfaktoren in Abhängigkeit von der mittleren Versuchstemperatur, der verwendeten Höchsttemperatur und dem Temperaturunterschied gegeben.Sie zeigt,dass der Trenneffekt beim Xenon etwa proportional der Differenz von Aussen - und Innentemperatur und der mittleren absoluten Temperatur ist.x Die angegebenen Atomgewichtsunterschiede entsprechen einem Trennrohr von 2 m Länge.

x. Clusius gibt in seiner Arbeit für leichtere Gase den Effekt der Trennung als proportional: $\frac{\Delta T}{T_{mittel}}$ an, was offenbar beim Xenon nicht der Fall ist.

~~SECRET~~

Zusammenfassend kann gesagt werden,dass bei Verwendung eines dampfgeheizten Doppelmantelrohres und einer mässigen Trennlänge (etwa 10 m) ein Effekt zu erwarten ist,der den gestellten Anforderungen genügt;die angereicherten Isotopen können bei geeigneter Dimensionierung wahrscheinlich in Mengen gewonnen werden,die für die vorliegenden Zwecke ausreichend sind.

Ferner hat Herr Suess eine Methode ausgearbeitet,die es gestattet, die erwartete Verschiebung des Isotopenverhältnisses nachzuweisen. Sie beruht auf folgender Ueberlegung:Das Isotop U^{235},dessen Anreicherung interessiert,trägt,wie aus der in der Tabelle angegebenen Häufigkeit und Halbwertszeit hervorgeht,nur wenig zur Gesamt-α-Aktivität bei.Eine Veränderung der α-Aktivität durch geringe Anreicherung von U^{235} wird daher mit einfachen Mitteln nicht nachgewiesen werden können.Es wird jedoch bei der Anreicherung von U^{235} zwangsläufig auch das Isotop U^{234} und zwar in etwas stärkerem Masse angereichert.Das U^{234} trägt - als Folgeprodukt mit U^{238} im radioaktiven Gleichgewicht stehend- trotz seines geringen mengenmässigen Anteiles im natürlichen Uran zur Gesamt -α-Aktivität ebensoviel bei wie das U^{238}.Wird z.B.das U^{234} um 10% angereichert,dann steigt hierdurch die Gesamt-α- Aktivität um 5%.Man hat dann zu erwarten,dass das U^{235} um mindestens 7% angereichert wurde.

Tabelle.

	Konzentration	Halbwertszeit
U^{238}	0,99	$4{,}56\cdot10^{9}$a
U^{235}	$7{,}2\cdot10^{-3}$	$7{,}13\cdot10^{8}$a
U^{234}	$6{,}1\cdot10^{-5}$	$2{,}7\cdot10^{5}$a

Die Gesamt-α-Aktivität lässt sich,wie Herr Suess in unserem Institut überprüft hat,leicht durch Messung der Entladungsgeschwindigkeit eines Elektrometers auf 1% genau bestimmen.Zur Messung wird ungefähr ein Gramm Uranoxyd benötigt.Die Verschiebung des Isotopenverhältnisses um wenige Prozente kann auf diese Weise leicht nachgewiesen werden.

Ueber einige Konstanten und Eigenschaften von UF_6.

Von R. Fleischmann. G 28 (an 108)

1. Allgemeines: Eine Abtrennung oder Anreicherung des Isotops U^{235} läßt sich – außer mit dem Massenspektrographen, – der nur sehr geringe Mengen liefern kann – nach unserer heutigen Kenntnis am ehesten mit dem Clusiusschen Trennrohrverfahren erreichen. Man muß dazu die einzige in der Nähe der Zimmertemperatur noch dampfförmige Verbindung UF_6 verwenden. Da dieser Stoff außerordentlich aggressiv ist, waren viele Vorversuche über die Möglichkeit des Arbeitens mit der Substanz erforderlich. Ueber Erfahrungen darüber wird im letzten Abschnitt berichtet.

dated [illegible] noted by

Leider gibt es noch keine vollständige theoretische Behandlung des Trennrohrverfahrens, mit der sich die Trennvorgänge auf Grund bekannter bzw. meßbarer Konstanten der zu trennenden Stoffe vollständig vorausberechnen lassen. Die nahezu übereinstimmenden Theorien von Waldmann[1)] und von Furry, Jones u. Onsager[2)] beziehen sich nur auf den ebenen Fall. Sie lassen sich aber wenigstens qualitativ auf den zylindrischen Fall übertragen. Damit läßt sich die richtige Dimensionierung einer Trennanlage abschätzen, wenn einige Konstanten des im Trennrohr verwendeten Gases bekannt sind, so vor allem der Koeffizient der inneren Reibung η und die Gasdichte ϱ, oder bei einem gesättigten Dampf, das Molekulargewicht M und der Dampfdruck p in Abhängigkeit von der Temperatur. Der noch erforderliche Diffusionskoeffizient D kann nach der wohl ausnahmslos bestätigten Näherungsbeziehung $D \cong 1{,}4 \cdot \frac{\eta}{\varrho}$ berechnet werden.

Für UF_6 ist η noch nicht gemessen. Der Dampfdruck zwischen 37° und 56° C ist offenbar nur ungenau bestimmt. Er wird vor allem für niedrige Temperaturen benötigt, wo eine Extrapolation nur sehr unsichere Werte liefern kann. Falls die UF_6-Moleküle im Dampfzustand assoziiert wären, würde abgesehen von der Gasdichte auch der Koeffizient der Thermodiffusion noch stark beeinflußt. Da HF in Dampfform als H_6F_6 auftritt und z.B. AlF_3 stark assoziiert, ist es wichtig zu prüfen, ob UF_6 das ebenfalls tut oder nicht.

Die für die Dimensionierung des Trennrohres maßgebende Größe H^* (nach Waldmann) oder $\frac{1}{2A_d}$ (nach Furry u. Mitarb.) ist proportional $\frac{\varrho}{\eta \cdot D}$ oder, da man $D \cong 1{,}4 \cdot \frac{\eta}{\varrho}$ setzen kann, proportional $\frac{\varrho^2}{\eta^2}$. Die Abhängigkeit von ϱ und η ist quadratisch, eine Unsicherheit dieser Größen geht daher besonders stark ein.

Unter diesen Umständen war es erforderlich 1. den Koeffizienten der inneren Reibung η, 2. den Dampfdruck p in Abhängigkeit von der Temperatur und 3. die Dampfdichte für eine spezielle Temperatur zu messen. Als Nebenergebnis wurde auch der Koeffizient der Wärmeleitung λ' näherungsweise bestimmt und zwar als Mittelwert für große Temperaturunterschiede. Dieser ist für den Energieaufwand maßgebend, der für die Trennung benötigt wird.

2. Koeffizient der inneren Reibung.

Meßverfahren: Es wurde das Verhältnis der Reibungskoeffizienten für UF_6 und für Luft gemessen. Zur Erprobung der Apparatur wurden auch Messungen mit CO_2, N_2, und H_2 durchgeführt. Die Versuchsanordnung (Abb.1) bestand aus einer drehbaren Scheibe, die an einem dünnen Platinfaden aufgehängt war und die zwischen zwei festen Scheiben Dreh=

schwingungen ausführte. Gemessen wurde das logarithmische Dekrement der gedämpften Schwingung, das bis auf kleine Korrektionsgrößen proportional ist dem Koeffizienten η.

Abb. 1. Versuchsanordnung

Das Versuchsgefäß bestand aus Glas, die Metallteile aus vernickeltem Messing. Die festen Scheiben wurden durch 3 Metalleisten gehalten, die an einem Metallschliff befestigt waren. Dieserwar mit einem Glasschliff verkittet,

der oben in den Kern eines großen Glasschliffs überging. Die übrigen Einzelheiten sind aus der Abb.1 zu entnehmen. Das drehbare System trug unten ein kleines astatisches Magnetnadelpaar. Bei geeigneter rhythmischer Annäherung eines schwachen Magneten konnte die Drehschwingung angeregt werden. Auf der drehbaren Scheibe war eine Marke angebracht, deren Bewegung mit einem Ablesemikroskop für große Gegenstandsweite durch die Glaswand hindurch beobachtet werden konnte. Die Schwingungsweite wurde auf de Okularteilung des Mikroskops abgelesen. Die volle Schwingungsdauer der drehbaren Scheibe betrug ziemlich genau 15 sec. In Luft war das Dekrement $\lambda = 0,01454$, d.h. es waren rund 21 Schwingungen erforderlich, um die Amplitud auf die Hälfte zu bringen.

Es schien möglich, daß sich das UF_6-Gas während der Messung zersetzt und dadurch Fehler in der Bestimmun von η entstehen. Nach folgenden Beobachtungen kann man aber sicher sein, daß solche Einflüsse weit unterhalb de Meßgenauigkeit liegen. Da das Dämpfungsdekrement bei kle nen Drucken sich sehr schnell mit dem Druck ändert (vgl. Abb.2), kann man aus dem Dekrement sehr empfindlich auf Gasreste schließen. Vor der Messung mit UF_6 wurde das Versuchsgefäß ausgepumpt, während sich das UF_6 in flüssiger Luft befand, und das Dämpfungsdekrement $\lambda = 0,000\,25$ bestimmt, entsprechend etwa $0,45 \cdot 10^{-3}$ mm Hg. Dann wurde das UF_6 auf Zimmertemperatur gebracht und gemessen; dabe war $\lambda = 0,01349$. Nach dem sofortigen Wiedereinfrieren war die Dämpfung $\lambda = 0,000\,52$. Der Druck im Versuchsgefä läßt sich daraus zu $2,1 \cdot 10^{-3}$ mm Hg abschätzen. Es sind also nur verschwindende Gasspuren entstanden. Aehnliche Beobachtungen wurden mehrfach ausgeführt. Am Versuchsge-

fäß waren auch nach längerer Zeit kaum Spuren eines Niederschlags zu sehen.

Messungen: Um die Eigendämpfung des Systems zu erhalten, wurden zunächst Dämpfungsmessungen bei Hochvakuum ausgeführt. Aus der Abnahme der Dämpfung war zu ersehen, daß sich während der ersten Stunde des Pumpens noch Gasreste geltend machten. Nach 2 bis 6-stündigem Pumpen wurde ein konstanter Minimalwert des Dekrements 0,00018 erreicht; das ist rund 1,5 % der Dämpfung in Luft. Dieser Wert wurde als Eigendämpfung des Systems angesehen. Das Ergebnis der Dämpfungsmessungen mit UF_6 und mit Luft bei verschiedenen Drucken ist in Abb.2 wiedergegeben. Die nach der kinetische Gastheorie zu erwartende Konstanz von η, (so lange die freie Weglänge $\ll$ als die Apparatdimensionen) ist mindestens bis 5 mm Druck herab erfüllt.

Das Verhältnis der Koeffizienten der inneren Reibun ergibt sich aus $\frac{\eta}{\eta_0} = \frac{\lambda - K}{\lambda_0 - K}$, dabei ist η der Reibungskoeffizient für das unbekannte Gas (UF_6), η_0 der für das bekannt (Luft), λ und λ_0 das gemessene logarithmische Dekrement fü das unbekannte und bekannte Gas, K die Eigendämpfung.

Die Dekremente und relativen Reibungskoeffizienten nach eigenen Messungen und nach Literaturwerten sind in Tab.1 zusammengestellt. Setzt man bei Zimmertemperatur ($T = 293^\circ$ K) für Luft $\eta = 1809 \cdot 10^{-7}$, so ergibt sich für UF_6 $\eta = 1673 \cdot 10^{-7}$.

Tab. 1

Relative Reibungskoeffizienten reduz. auf 20° C.

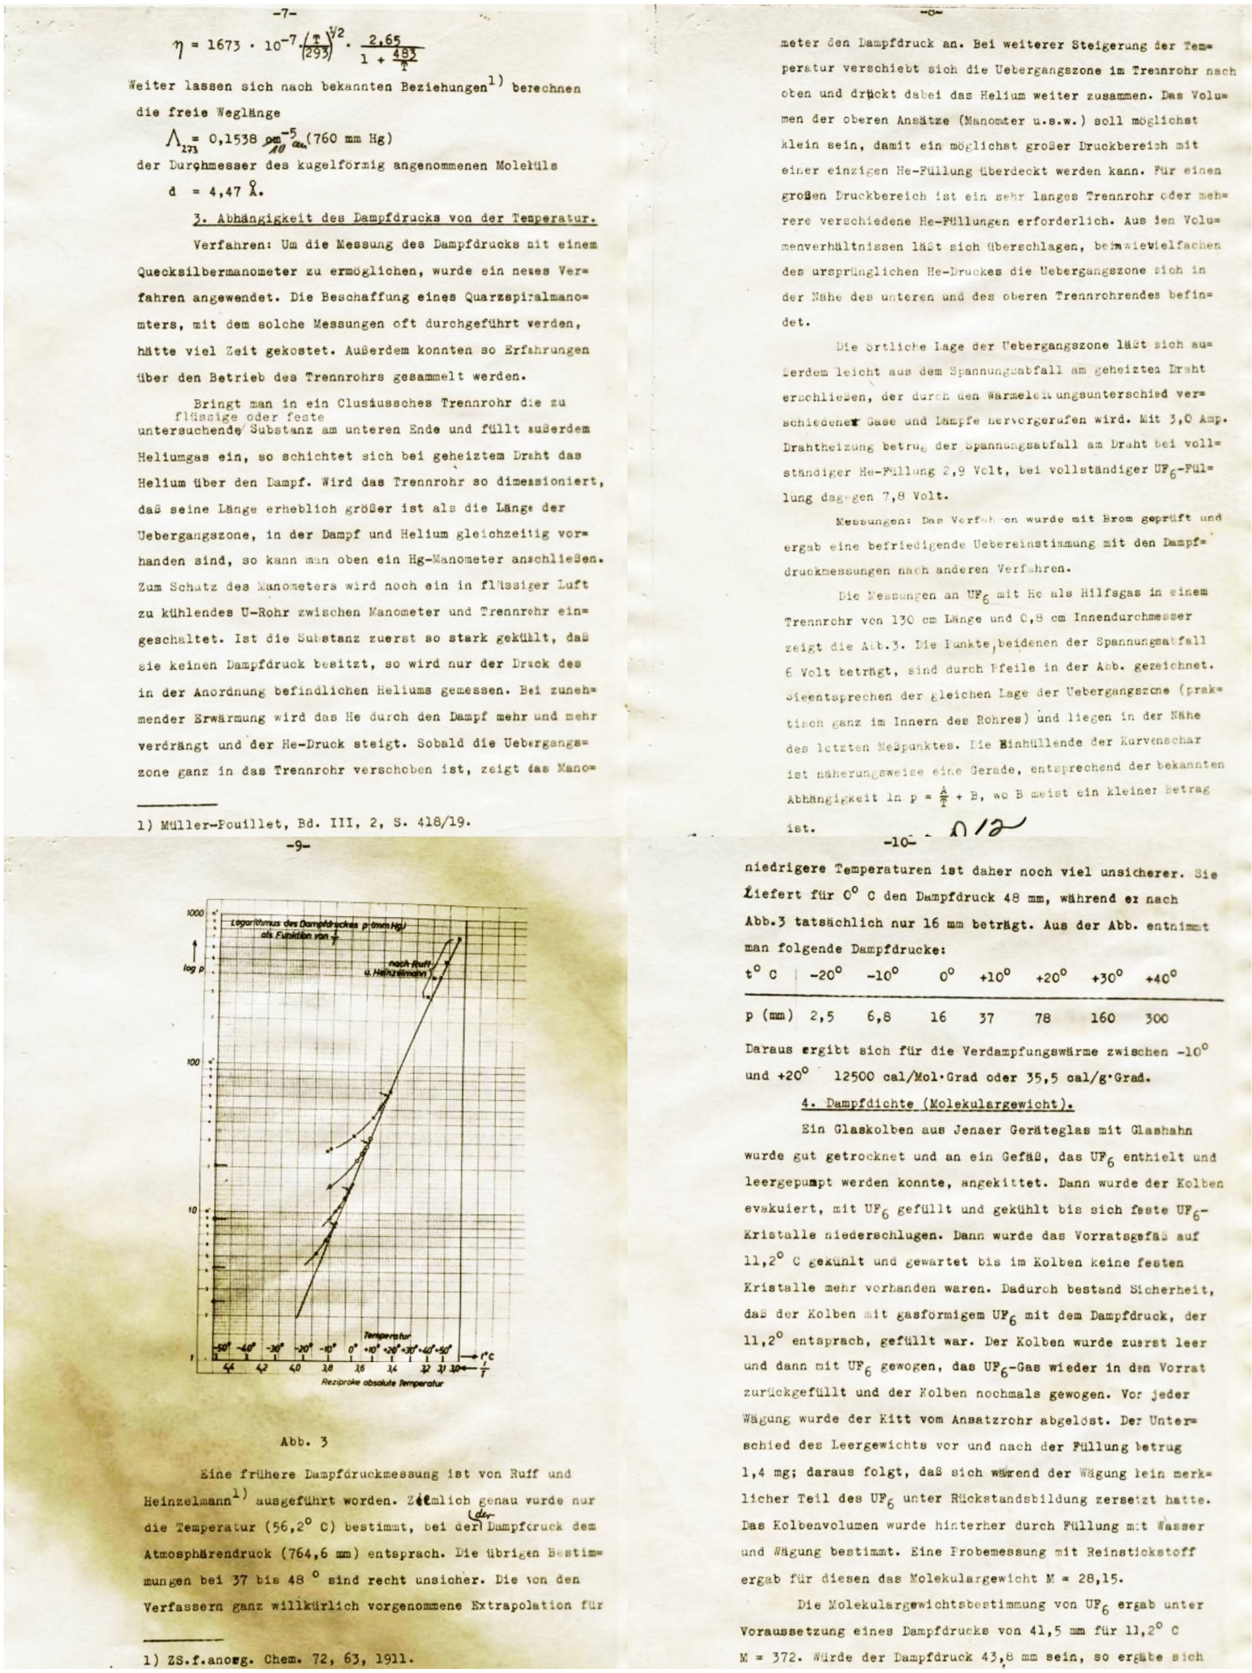
Landolt-Börnstein	Luft	N_2	CO_2	H_2	UF_6
Eg I 143 ff.	1	0,958	0,800	~0,485	–
Eg IIa 137	1	0,960	–	0,483	–
Eg IIIa 190/191	1	–	0,808	–	–
Eg IIIa 185	1*)	0,964	0,807	0,482	–
Eigene Messungen	1	0,963	0,810	0,492	0,925

Bei den eigenen Messungen wurde getrocknete CO_2-freie Luft, Reinstickstoff (von Osram), CO_2 und H_2 aus gewöhnlichen Gasflaschen verwendet.

*Absolutwert für $t = 20^\circ$ $\eta = 1809 \cdot 10^{-7}$.

Die Temperaturabhängigkeit von η ist mit sehr gute Näherungfür alle bisher untersuchten Gase $\sim \frac{T^{1/2}}{1 + \frac{C}{T}}$. Dabe ist die sogenannte Sutherlandsche Konstante C empirisch $= 1,47 \cdot T_s$, wo T_s die Siedetemperatur ist bzw. die Temperatur, bei der der Dampfdruck der Substanz 760 mm beträgt. Für UF_6 ist daher $C = 1,47 \cdot (56 + 273) = 483$ anzunehmen. Also wird für UF_6

Figure D.126: Production and testing of uranium hexafluoride in 1940 [G-28].



-7-

$$\eta = 1673 \cdot 10^{-7} \cdot \left(\frac{T}{293}\right)^{1/2} \cdot \frac{2{,}65}{1 + \frac{483}{T}}$$

Weiter lassen sich nach bekannten Beziehungen[1] berechnen die freie Weglänge

$\Lambda_{273} = 0{,}1538 \cdot 10^{-5}\,\mathrm{cm}$ (760 mm Hg)

der Durchmesser des kugelförmig angenommenen Moleküls

d = 4,47 Å.

3. Abhängigkeit des Dampfdrucks von der Temperatur.

Verfahren: Um die Messung des Dampfdrucks mit einem Quecksilbermanometer zu ermöglichen, wurde ein neues Verfahren angewendet. Die Beschaffung eines Quarzspiralmanometers, mit dem solche Messungen oft durchgeführt werden, hätte viel Zeit gekostet. Außerdem konnten so Erfahrungen über den Betrieb des Trennrohrs gesammelt werden.

Bringt man in ein Clusiussches Trennrohr die zu untersuchende flüssige oder feste Substanz am unteren Ende und füllt außerdem Heliumgas ein, so schichtet sich bei geheiztem Draht das Helium über den Dampf. Wird das Trennrohr so dimensioniert, daß seine Länge erheblich größer ist als die Länge der Uebergangszone, in der Dampf und Helium gleichzeitig vorhanden sind, so kann man oben ein Hg-Manometer anschließen. Zum Schutz des Manometers wird noch ein in flüssiger Luft zu kühlendes U-Rohr zwischen Manometer und Trennrohr eingeschaltet. Ist die Substanz zuerst so stark gekühlt, daß sie keinen Dampfdruck besitzt, so wird nur der Druck des in der Anordnung befindlichen Heliums gemessen. Bei zunehmender Erwärmung wird das He durch den Dampf mehr und mehr verdrängt und der He-Druck steigt. Sobald die Uebergangszone ganz in das Trennrohr verschoben ist, zeigt das Manometer den Dampfdruck an. Bei weiterer Steigerung der Temperatur verschiebt sich die Uebergangszone im Trennrohr nach oben und drückt dabei das Helium weiter zusammen. Das Volumen der oberen Ansätze (Manometer u.s.w.) soll möglichst klein sein, damit ein möglichst großer Druckbereich mit einer einzigen He-Füllung überdeckt werden kann. Für einen großen Druckbereich ist ein sehr langes Trennrohr oder mehrere verschiedene He-Füllungen erforderlich. Aus den Volumenverhältnissen läßt sich überschlagen, beim wievielfachen des ursprünglichen He-Druckes die Uebergangszone sich in der Nähe des unteren und des oberen Trennrohrendes befindet.

---

[1] Müller-Pouillet, Bd. III, 2, S. 418/19.

-8-

Die örtliche Lage der Uebergangszone läßt sich außerdem leicht aus dem Spannungsabfall am geheizten Draht erschließen, der durch den Wärmeleitungsunterschied verschiedener Gase und Dämpfe hervorgerufen wird. Mit 3,0 Amp. Drahtheizung betrug der Spannungsabfall am Draht bei vollständiger He-Füllung 2,9 Volt, bei vollständiger UF_6-Füllung dagegen 7,8 Volt.

Messungen: Das Verfahren wurde mit Brom geprüft und ergab eine befriedigende Uebereinstimmung mit den Dampfdruckmessungen nach anderen Verfahren.

Die Messungen an UF_6 mit He als Hilfsgas in einem Trennrohr von 130 cm Länge und 0,8 cm Innendurchmesser zeigt die Abb.3. Die Punkte, bei denen der Spannungsabfall 6 Volt beträgt, sind durch Pfeile in der Abb. gezeichnet. Sie entsprechen der gleichen Lage der Uebergangszone (praktisch ganz im Innern des Rohres) und liegen in der Nähe des letzten Meßpunktes. Die Einhüllende der Kurvenschar ist näherungsweise eine Gerade, entsprechend der bekannten Abhängigkeit $\ln p = \frac{A}{T} + B$, wo B meist ein kleiner Betrag ist.

D12

-9-

Abb. 3

Eine frühere Dampfdruckmessung ist von Ruff und Heinzelmann[1] ausgeführt worden. Ziemlich genau wurde nur die Temperatur (56,2° C) bestimmt, bei der der Dampfdruck dem Atmosphärendruck (764,6 mm) entsprach. Die übrigen Bestimmungen bei 37 bis 48 ° sind recht unsicher. Die von den Verfassern ganz willkürlich vorgenommene Extrapolation für niedrigere Temperaturen ist daher noch viel unsicherer. Sie liefert für 0° C den Dampfdruck 48 mm, während er nach Abb.3 tatsächlich nur 16 mm beträgt. Aus der Abb. entnimmt man folgende Dampfdrucke:

---

[1] ZS.f.anorg. Chem. 72, 63, 1911.

-10-

t° C	-20°	-10°	0°	+10°	+20°	+30°	+40°
p (mm)	2,5	6,8	16	37	78	160	300

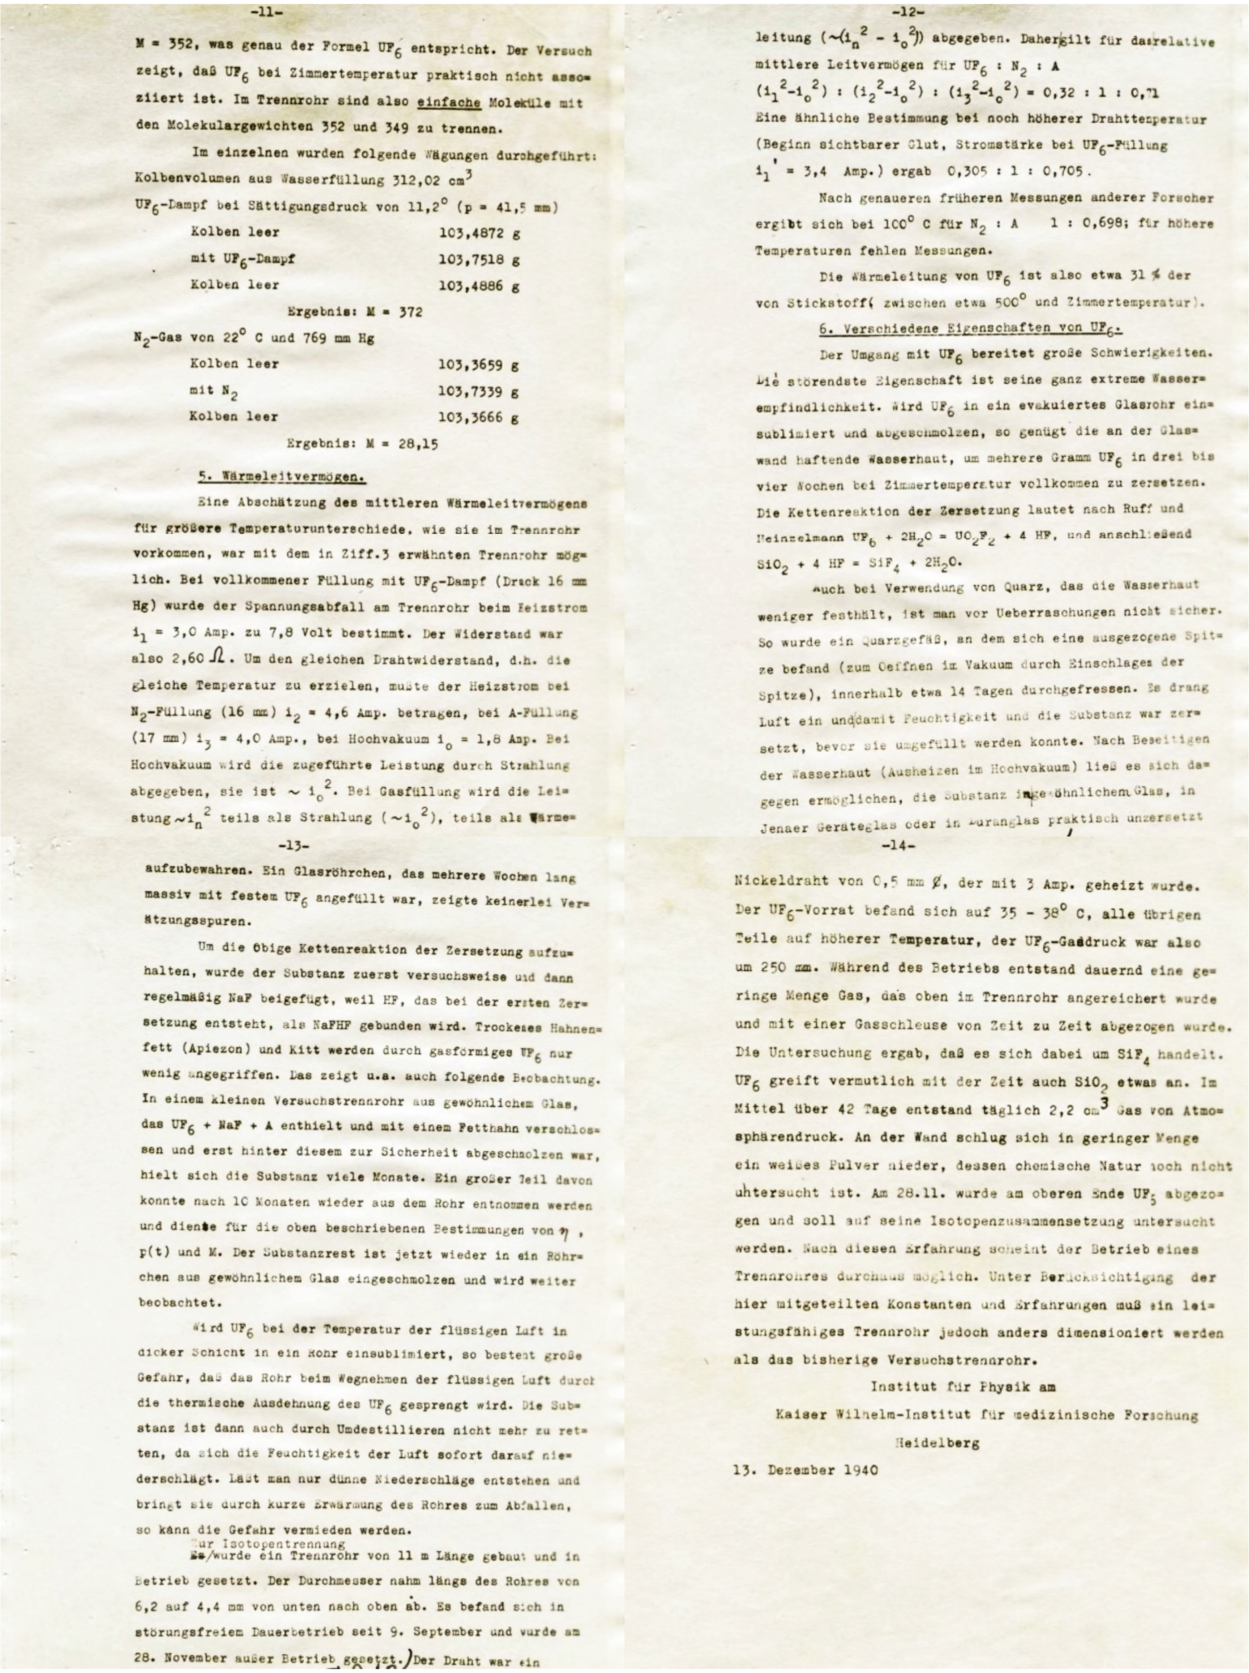
Daraus ergibt sich für die Verdampfungswärme zwischen -10° und +20° 12500 cal/Mol·Grad oder 35,5 cal/g·Grad.

4. Dampfdichte (Molekulargewicht).

Ein Glaskolben aus Jenaer Geräteglas mit Glashahn wurde gut getrocknet und an ein Gefäß, das UF_6 enthielt und leergepumpt werden konnte, angekittet. Dann wurde der Kolben evakuiert, mit UF_6 gefüllt und gekühlt bis sich feste UF_6-Kristalle niederschlugen. Dann wurde das Vorratsgefäß auf 11,2° C gekühlt und gewartet bis im Kolben keine festen Kristalle mehr vorhanden waren. Dadurch bestand Sicherheit, daß der Kolben mit gasförmigem UF_6 mit dem Dampfdruck, der 11,2° entsprach, gefüllt war. Der Kolben wurde zuerst leer und dann mit UF_6 gewogen, das UF_6-Gas wieder in den Vorrat zurückgefüllt und der Kolben nochmals gewogen. Vor jeder Wägung wurde der Kitt vom Ansatzrohr abgelöst. Der Unterschied des Leergewichts vor und nach der Füllung betrug 1,4 mg; daraus folgt, daß sich während der Wägung kein merklicher Teil des UF_6 unter Rückstandsbildung zersetzt hatte. Das Kolbenvolumen wurde hinterher durch Füllung mit Wasser und Wägung bestimmt. Eine Probemessung mit Reinstickstoff ergab für diesen das Molekulargewicht M = 28,15.

Die Molekulargewichtsbestimmung von UF_6 ergab unter Voraussetzung eines Dampfdrucks von 41,5 mm für 11,2° C M = 372. Würde der Dampfdruck 43,8 mm sein, so ergäbe sich

Figure D.127: Production and testing of uranium hexafluoride in 1940 [G-28].



M = 352, was genau der Formel UF_6 entspricht. Der Versuch zeigt, daß UF_6 bei Zimmertemperatur praktisch nicht assoziiert ist. Im Trennrohr sind also einfache Moleküle mit den Molekulargewichten 352 und 349 zu trennen.

Im einzelnen wurden folgende Wägungen durchgeführt:
Kolbenvolumen aus Wasserfüllung 312,02 cm^3
UF_6-Dampf bei Sättigungsdruck von 11,2° (p = 41,5 mm)

Kolben leer	103,4872 g
mit UF_6-Dampf	103,7518 g
Kolben leer	103,4886 g

Ergebnis: M = 372

N_2-Gas von 22° C und 769 mm Hg

Kolben leer	103,3659 g
mit N_2	103,7339 g
Kolben leer	103,3666 g

Ergebnis: M = 28,15

5. Wärmeleitvermögen.

Eine Abschätzung des mittleren Wärmeleitvermögens für größere Temperaturunterschiede, wie sie im Trennrohr vorkommen, war mit dem in Ziff. 3 erwähnten Trennrohr möglich. Bei vollkommener Füllung mit UF_6-Dampf (Druck 16 mm Hg) wurde der Spannungsabfall am Trennrohr beim Heizstrom i_1 = 3,0 Amp. zu 7,8 Volt bestimmt. Der Widerstand war also 2,60 Ω. Um den gleichen Drahtwiderstand, d.h. die gleiche Temperatur zu erzielen, mußte der Heizstrom bei N_2-Füllung (16 mm) i_2 = 4,6 Amp. betragen, bei A-Füllung (17 mm) i_3 = 4,0 Amp., bei Hochvakuum i_o = 1,8 Amp. Bei Hochvakuum wird die zugeführte Leistung durch Strahlung abgegeben, sie ist $\sim i_o^2$. Bei Gasfüllung wird die Leistung $\sim i_n^2$ teils als Strahlung ($\sim i_o^2$), teils als Wärmeleitung ($\sim (i_n^2 - i_o^2)$) abgegeben. Daher gilt für dasrelative mittlere Leitvermögen für $UF_6 : N_2 : A$
$(i_1^2-i_o^2) : (i_2^2-i_o^2) : (i_3^2-i_o^2) = 0,32 : 1 : 0,71$
Eine ähnliche Bestimmung bei noch höherer Drahttemperatur (Beginn sichtbarer Glut, Stromstärke bei UF_6-Füllung i_1' = 3,4 Amp.) ergab 0,305 : 1 : 0,705.

Nach genaueren früheren Messungen anderer Forscher ergibt sich bei 100° C für $N_2 : A$ 1 : 0,698; für höhere Temperaturen fehlen Messungen.

Die Wärmeleitung von UF_6 ist also etwa 31 % der von Stickstoff(zwischen etwa 500° und Zimmertemperatur).

6. Verschiedene Eigenschaften von UF_6.

Der Umgang mit UF_6 bereitet große Schwierigkeiten. Die störendste Eigenschaft ist seine ganz extreme Wasserempfindlichkeit. Wird UF_6 in ein evakuiertes Glasrohr einsublimiert und abgeschmolzen, so genügt die an der Glaswand haftende Wasserhaut, um mehrere Gramm UF_6 in drei bis vier Wochen bei Zimmertemperatur vollkommen zu zersetzen. Die Kettenreaktion der Zersetzung lautet nach Ruff und Heinzelmann $UF_6 + 2H_2O = UO_2F_2 + 4\ HF$, und anschließend $SiO_2 + 4\ HF = SiF_4 + 2H_2O$.

Auch bei Verwendung von Quarz, das die Wasserhaut weniger festhält, ist man vor Ueberraschungen nicht sicher. So wurde ein Quarzgefäß, an dem sich eine ausgezogene Spitze befand (zum Oeffnen im Vakuum durch Einschlagen der Spitze), innerhalb etwa 14 Tagen durchgefressen. Es drang Luft ein und damit Feuchtigkeit und die Substanz war zersetzt, bevor sie umgefüllt werden konnte. Nach Beseitigen der Wasserhaut (Ausheizen im Hochvakuum) ließ es sich dagegen ermöglichen, die Substanz in gewöhnlichem Glas, in Jenaer Geräteglas oder in Duranglas praktisch unzersetzt aufzubewahren. Ein Glasröhrchen, das mehrere Wochen lang massiv mit festem UF_6 angefüllt war, zeigte keinerlei Verätzungsspuren.

Um die obige Kettenreaktion der Zersetzung aufzuhalten, wurde der Substanz zuerst versuchsweise und dann regelmäßig NaF beigefügt, weil HF, das bei der ersten Zersetzung entsteht, als NaFHF gebunden wird. Trockenes Hahnenfett (Apiezon) und Kitt werden durch gasförmiges UF_6 nur wenig angegriffen. Das zeigt u.a. auch folgende Beobachtung. In einem kleinen Versuchstrennrohr aus gewöhnlichem Glas, das UF_6 + NaF + A enthielt und mit einem Fetthahn verschlossen und erst hinter diesem zur Sicherheit abgeschmolzen war, hielt sich die Substanz viele Monate. Ein großer Teil davon konnte nach 10 Monaten wieder aus dem Rohr entnommen werden und diente für die oben beschriebenen Bestimmungen von η, p(t) und M. Der Substanzrest ist jetzt wieder in ein Röhrchen aus gewöhnlichem Glas eingeschmolzen und wird weiter beobachtet.

Wird UF_6 bei der Temperatur der flüssigen Luft in dicker Schicht in ein Rohr einsublimiert, so besteht große Gefahr, daß das Rohr beim Wegnehmen der flüssigen Luft durch die thermische Ausdehnung des UF_6 gesprengt wird. Die Substanz ist dann auch durch Umdestillieren nicht mehr zu retten, da sich die Feuchtigkeit der Luft sofort darauf niederschlägt. Läßt man nur dünne Niederschläge entstehen und bringt sie durch kurze Erwärmung des Rohres zum Abfallen, so kann die Gefahr vermieden werden.

~~Es~~ Zur Isotopentrennung wurde ein Trennrohr von 11 m Länge gebaut und in Betrieb gesetzt. Der Durchmesser nahm längs des Rohres von 6,2 auf 4,4 mm von unten nach oben ab. Es befand sich in störungsfreiem Dauerbetrieb seit 9. September und wurde am 28. November außer Betrieb gesetzt.) Der Draht war ein Nickeldraht von 0,5 mm Ø, der mit 3 Amp. geheizt wurde. Der UF_6-Vorrat befand sich auf 35 - 38° C, alle übrigen Teile auf höherer Temperatur, der UF_6-Gasdruck war also um 250 mm. Während des Betriebs entstand dauernd eine geringe Menge Gas, das oben im Trennrohr angereichert wurde und mit einer Gasschleuse von Zeit zu Zeit abgezogen wurde. Die Untersuchung ergab, daß es sich dabei um SiF_4 handelt. UF_6 greift vermutlich mit der Zeit auch SiO_2 etwas an. Im Mittel über 42 Tage entstand täglich 2,2 cm^3 Gas von Atmosphärendruck. An der Wand schlug sich in geringer Menge ein weißes Pulver nieder, dessen chemische Natur noch nicht untersucht ist. Am 28.11. wurde am oberen Ende UF_5 abgezogen und soll auf seine Isotopenzusammensetzung untersucht werden. Nach diesen Erfahrung scheint der Betrieb eines Trennrohres durchaus möglich. Unter Berücksichtigung der hier mitgeteilten Konstanten und Erfahrungen muß ein leistungsfähiges Trennrohr jedoch anders dimensioniert werden als das bisherige Versuchstrennrohr.

Bericht über die Arbeitsbesprechung
bei den I.G.Farbwerken am 6.11.42.

Teilnehmer: Institut für phys.Chemie, Hamburg:
Prof.Harteck, Dr.Groth.
I.G.Farbwerke, Leverkusen:
Dr.Noack, Dr.Kwasnik.

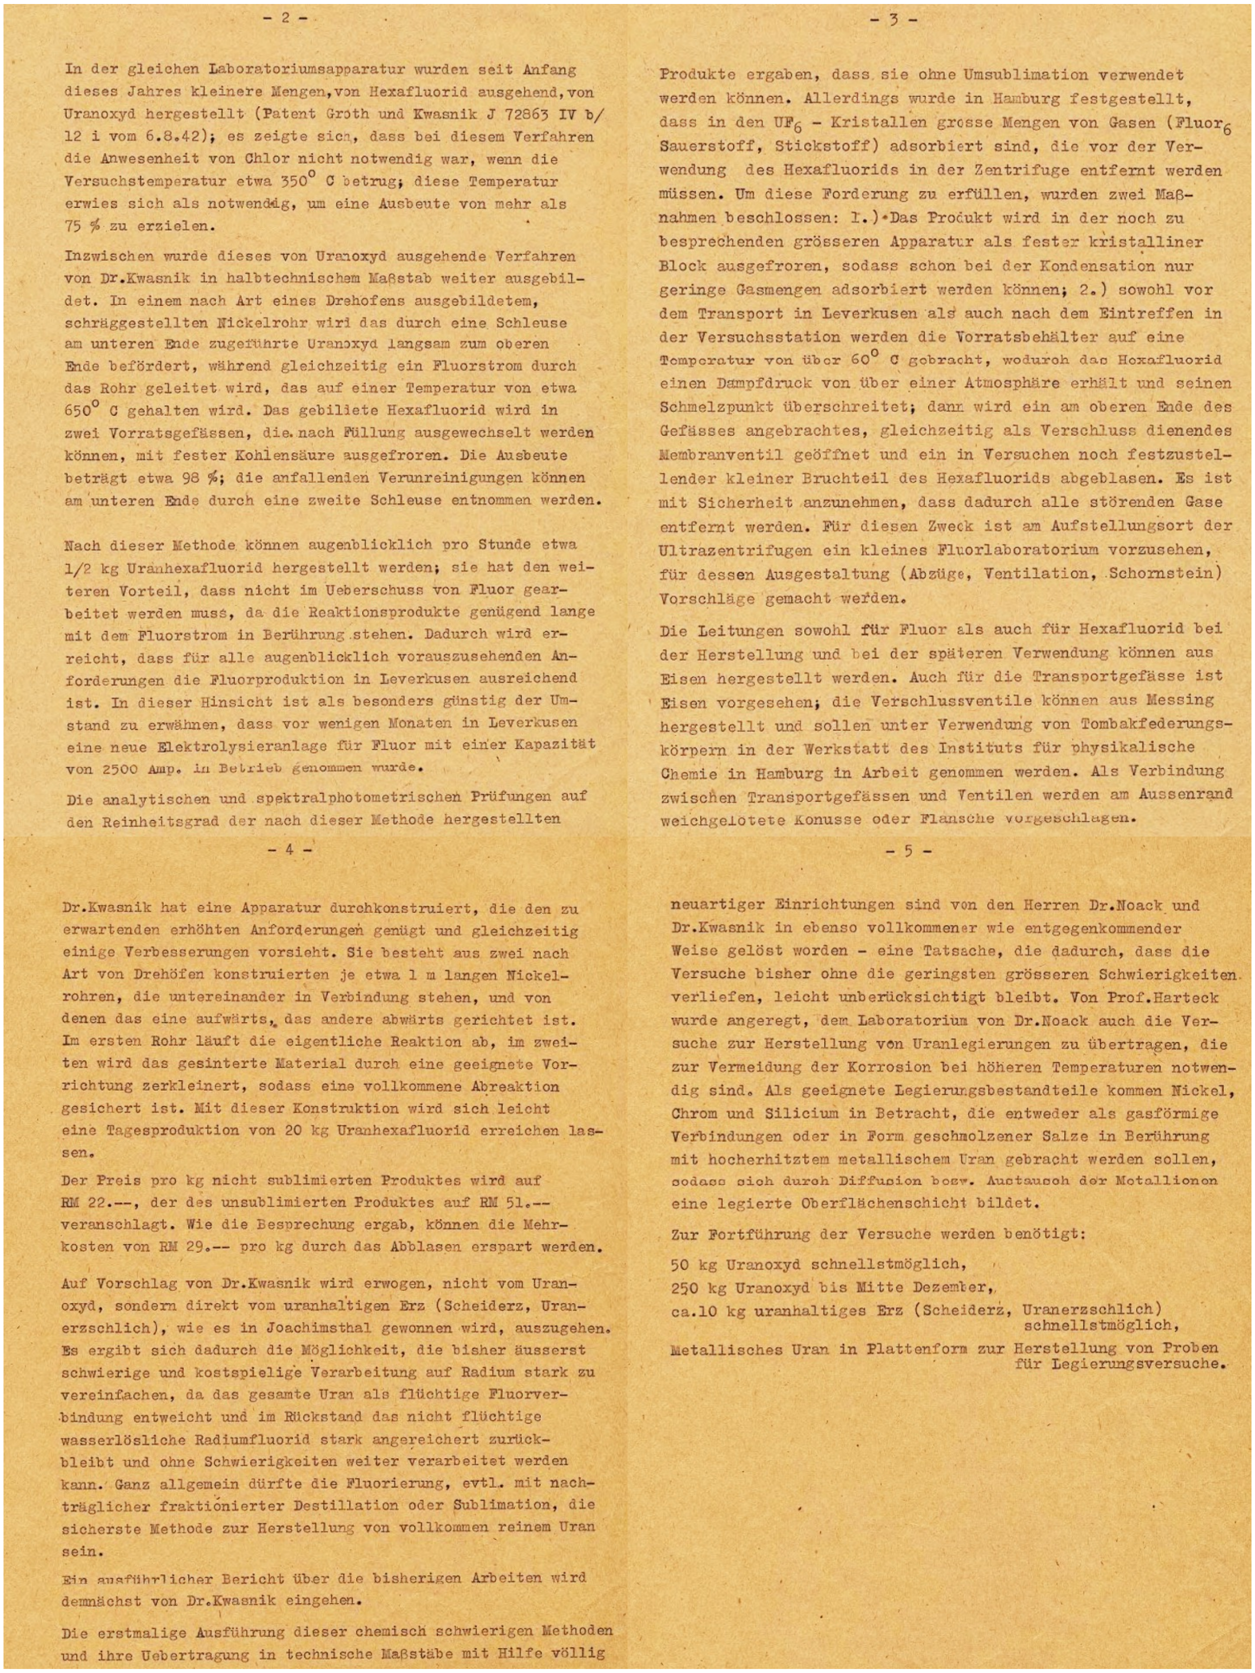
Betr.: Herstellung von Uranhexafluorid im halbtechnischen Maßstab. Untersuchung der Legierungsfähigkeit von metallischem Uran.

Für die früheren Versuchszwecke erfolgte die Herstellung der benötigten kleineren Mengen von Uranhexafluorid in Anlehnung an die Angaben von O.Ruff und A.Heinzelmann, A.v.Grosse und P.Kronenberg, P.Henkel und W.Klemm aus metallischem Uran. Dieses wurde in einem Nickelschiffchen in ein Nickelrohr von 40 cm Länge und 4 cm Durchmesser gebracht, das auf beiden Seiten mit Schliffen versehen war, in welche Nickelkonusse passten. Diese trugen kleine Schliffansätze, an die Quarzschliffe angesetzt werden konnten.

Das metallische Uran wurde entweder mit wasserfreiem Calciumchlorid vermischt, worauf im trockenen Stickstoffstrom reines Fluor durch das Nickelrohr geleitet wurde – Chlor ist für das Einsetzen der Reaktion des Urans mit Fluor und zur Erreichung der 6. Wertigkeitsstufe des Urans als Katalysator notwendig – oder es wurde mit Chlorfluorid gearbeitet, das den Zusatz von Chlorcalcium überflüssig machte.

Zu Beginn der Reaktion musste das Nickelrohr mit Wasser gekühlt werden; später läuft die Reaktion ohne Kühlung weiter, ohne dass zu starke Erwärmungen auftreten; zum Schluss kann das Nickelrohr leicht erwärmt werden, um eine vollständige Abreaktion des Urans zu erreichen. Das gebildete Hexafluorid wurde mit flüssigem Sauerstoff in Quarzgefässen ausgefroren und in einer Stockschen Vakuumapparatur fraktioniert, bis es eine reine weisse Farbe zeigt.

Figure D.129: Production and testing of uranium hexafluoride in 1942 [G-157].



In der gleichen Laboratoriumsapparatur wurden seit Anfang dieses Jahres kleinere Mengen, von Hexafluorid ausgehend, von Uranoxyd hergestellt (Patent Groth und Kwasnik J 72863 IV b/12 i vom 6.8.42); es zeigte sich, dass bei diesem Verfahren die Anwesenheit von Chlor nicht notwendig war, wenn die Versuchstemperatur etwa 350° C betrug; diese Temperatur erwies sich als notwendig, um eine Ausbeute von mehr als 75 % zu erzielen.

Inzwischen wurde dieses von Uranoxyd ausgehende Verfahren von Dr.Kwasnik in halbtechnischem Maßstab weiter ausgebildet. In einem nach Art eines Drehofens ausgebildetem, schräggestellten Nickelrohr wird das durch eine Schleuse am unteren Ende zugeführte Uranoxyd langsam zum oberen Ende befördert, während gleichzeitig ein Fluorstrom durch das Rohr geleitet wird, das auf einer Temperatur von etwa 650° C gehalten wird. Das gebildete Hexafluorid wird in zwei Vorratsgefässen, die nach Füllung ausgewechselt werden können, mit fester Kohlensäure ausgefroren. Die Ausbeute beträgt etwa 98 %; die anfallenden Verunreinigungen können am unteren Ende durch eine zweite Schleuse entnommen werden.

Nach dieser Methode können augenblicklich pro Stunde etwa 1/2 kg Uranhexafluorid hergestellt werden; sie hat den weiteren Vorteil, dass nicht im Ueberschuss von Fluor gearbeitet werden muss, da die Reaktionsprodukte genügend lange mit dem Fluorstrom in Berührung stehen. Dadurch wird erreicht, dass für alle augenblicklich vorauszusehenden Anforderungen die Fluorproduktion in Leverkusen ausreichend ist. In dieser Hinsicht ist als besonders günstig der Umstand zu erwähnen, dass vor wenigen Monaten in Leverkusen eine neue Elektrolysieranlage für Fluor mit einer Kapazität von 2500 Amp. in Betrieb genommen wurde.

Die analytischen und spektralphotometrischen Prüfungen auf den Reinheitsgrad der nach dieser Methode hergestellten Produkte ergaben, dass sie ohne Umsublimation verwendet werden können. Allerdings wurde in Hamburg festgestellt, dass in den UF$_6$ - Kristallen grosse Mengen von Gasen (Fluor$_6$ Sauerstoff, Stickstoff) adsorbiert sind, die vor der Verwendung des Hexafluorids in der Zentrifuge entfernt werden müssen. Um diese Forderung zu erfüllen, wurden zwei Maßnahmen beschlossen: 1.) Das Produkt wird in der noch zu besprechenden grösseren Apparatur als fester kristalliner Block ausgefroren, sodass schon bei der Kondensation nur geringe Gasmengen adsorbiert werden können; 2.) sowohl vor dem Transport in Leverkusen als auch nach dem Eintreffen in der Versuchsstation werden die Vorratsbehälter auf eine Temperatur von über 60° C gebracht, wodurch das Hexafluorid einen Dampfdruck von über einer Atmosphäre erhält und seinen Schmelzpunkt überschreitet; dann wird ein am oberen Ende des Gefässes angebrachtes, gleichzeitig als Verschluss dienendes Membranventil geöffnet und ein in Versuchen noch festzustellender kleiner Bruchteil des Hexafluorids abgeblasen. Es ist mit Sicherheit anzunehmen, dass dadurch alle störenden Gase entfernt werden. Für diesen Zweck ist am Aufstellungsort der Ultrazentrifugen ein kleines Fluorlaboratorium vorzusehen, für dessen Ausgestaltung (Abzüge, Ventilation, Schornstein) Vorschläge gemacht werden.

Die Leitungen sowohl für Fluor als auch für Hexafluorid bei der Herstellung und bei der späteren Verwendung können aus Eisen hergestellt werden. Auch für die Transportgefässe ist Eisen vorgesehen; die Verschlussventile können aus Messing hergestellt und sollen unter Verwendung von Tombakfederungskörpern in der Werkstatt des Instituts für physikalische Chemie in Hamburg in Arbeit genommen werden. Als Verbindung zwischen Transportgefässen und Ventilen werden am Aussenrand weichgelötete Konusse oder Flansche vorgeschlagen.

Dr.Kwasnik hat eine Apparatur durchkonstruiert, die den zu erwartenden erhöhten Anforderungen genügt und gleichzeitig einige Verbesserungen vorsieht. Sie besteht aus zwei nach Art von Drehöfen konstruierten je etwa 1 m langen Nickelrohren, die untereinander in Verbindung stehen, und von denen das eine aufwärts, das andere abwärts gerichtet ist. Im ersten Rohr läuft die eigentliche Reaktion ab, im zweiten wird das gesinterte Material durch eine geeignete Vorrichtung zerkleinert, sodass eine vollkommene Abreaktion gesichert ist. Mit dieser Konstruktion wird sich leicht eine Tagesproduktion von 20 kg Uranhexafluorid erreichen lassen.

Der Preis pro kg nicht sublimierten Produktes wird auf RM 22.--, der des unsublimierten Produktes auf RM 51.-- veranschlagt. Wie die Besprechung ergab, können die Mehrkosten von RM 29.-- pro kg durch das Abblasen erspart werden.

Auf Vorschlag von Dr.Kwasnik wird erwogen, nicht vom Uranoxyd, sondern direkt vom uranhaltigen Erz (Scheiderz, Uranerzschlich), wie es in Joachimsthal gewonnen wird, auszugehen. Es ergibt sich dadurch die Möglichkeit, die bisher äusserst schwierige und kostspielige Verarbeitung auf Radium stark zu vereinfachen, da das gesamte Uran als flüchtige Fluorverbindung entweicht und im Rückstand das nicht flüchtige wasserlösliche Radiumfluorid stark angereichert zurückbleibt und ohne Schwierigkeiten weiter verarbeitet werden kann. Ganz allgemein dürfte die Fluorierung, evtl. mit nachträglicher fraktionierter Destillation oder Sublimation, die sicherste Methode zur Herstellung von vollkommen reinem Uran sein.

Ein ausführlicher Bericht über die bisherigen Arbeiten wird demnächst von Dr.Kwasnik eingehen.

Die erstmalige Ausführung dieser chemisch schwierigen Methoden und ihre Uebertragung in technische Maßstäbe mit Hilfe völlig neuartiger Einrichtungen sind von den Herren Dr.Noack und Dr.Kwasnik in ebenso vollkommener wie entgegenkommender Weise gelöst worden - eine Tatsache, die dadurch, dass die Versuche bisher ohne die geringsten grösseren Schwierigkeiten verliefen, leicht unberücksichtigt bleibt. Von Prof.Harteck wurde angeregt, dem Laboratorium von Dr.Noack auch die Versuche zur Herstellung von Uranlegierungen zu übertragen, die zur Vermeidung der Korrosion bei höheren Temperaturen notwendig sind. Als geeignete Legierungsbestandteile kommen Nickel, Chrom und Silicium in Betracht, die entweder als gasförmige Verbindungen oder in Form geschmolzener Salze in Berührung mit hocherhitztem metallischem Uran gebracht werden sollen, sodass sich durch Diffusion bzw. Austausch der Metallionen eine legierte Oberflächenschicht bildet.

Zur Fortführung der Versuche werden benötigt:

50 kg Uranoxyd schnellstmöglich,
250 kg Uranoxyd bis Mitte Dezember,
ca.10 kg uranhaltiges Erz (Scheiderz, Uranerzschlich) schnellstmöglich,
Metallisches Uran in Plattenform zur Herstellung von Proben für Legierungsversuche.

APO 777 US ARMY

PRELIMINARY INTERROGATION REPORT 18 September 1945

PROF. DR. ULRICH HOFFMANN

1. PERSONAL HISTORY:

a. Citizenship: German.

b. Present Address: Grand Hotel, Strobl. Vienna address: Wien, 18 Bezirk, Cottagegasse 39.

c. Date and Place of Birth: 22 January 1903, Munich, Bavaria.

d. Description: Short; blonde but considerably bald; blinking eyes; married.

e. Education: PhD in chemistry from University of Berlin in 1926. Instructor at University of Berlin until 1936. Called to University of Rostock in 1936 where he became full professor in 1937. In April 1942 he was called to University of Vienna as Director of the Institute for Inorganic and Analytic Chemistry.

f. Political Affiliations: In 1933 joined the SA at advice of Berlin faculty and automatically became a Nazi in 1937. Never held office in NSDAP, but was a troop-leader in SA in 1943.

g. Military Service: Gefreiter in German Army from August to November of 1939. Was released for physical disability.

2. OCCUPATIONS: Research Scientist. Professor of Chemistry.

3. GENERAL INFORMATION: Dr. Hoffmann's research in the field of air interest was only in the development of the atomic bomb. Claims to have improved method of obtaining FLUOR, which is necessary to obtain UF6, one of the basic ingredients of the atomic bomb. Worked with Dr. Aristid Victor von Grosse (now believed working at the University of Chicago) at Berlin in 1931.

4. DISPOSITION: Dr. Hoffmann is under town arrest at Grand Hotel, Strobl until 15 September. His arrest can be extended for further interrogation. He is very willing and cooperative. It is requested that any headquarters interested in further interrogation of this subject forward a brief, outlining information desired to A C of S, A-2, Air Division, United States Forces in Austria.

(Supplementing PW INTELLIGENCE BULLETIN 1/26 item 12)

PW confirms the location of the Administration bldg of I.G. FARBEN, WERK SÜD. He states that in addition to the items previously reported as bein produced, "CHLORAL" (said to be trade name for a medical preparation), "PRESSTOFF" (bakelite type), "TETRA" cleanser, phosphorus and quicksilver were produced. The above production is in bldgs not previously reported.

According to PW the most vulnerable spot of the factory is the power plant located in the S part of the plant area.

A continuous flow of coal for the power plant comes by rail from the soft coal pit "GRUBE THEODOR" at ZSCHERNDORF.

6. Light Metal Works, BITTERFELD (Continued)

The power station at "GRUBE LEOPOLD" at HOLZWEISSIG (S of BITTERFELD) is said to supply electricity to BITTERFELD and nearby communities.

Both power stations were subjected to air raids but no serious damage was caused up to Sept 44.

Rumor has it that plans were to transfer salvaged machinery from LEUNA into the already prepared bldgs, in E part of WERK SUD complex, (W of BITTERFELD RR station) and to produce on a reduced scale. It was mentioned that soon it would be impossible to carry on production in LEUNA.

W of rd leading from WERK SUD to WERK NORD, and S of RR is an Aluminum plant which was built in 42/43 and started operation summer 43.

WERK NORD is supposed to be mainly a light metal plant, similar to WERK SUD.

Part of the ANILIN Factory in GREPPIN is underground (E of RR) and great secrecy is enforced. PW's brother is employed at this factory as a mechanic and claims that this large enterprise produces poison gas which is compressed into steel bottles.

Among other products are paints, HCL (Salzsäure), Nitrogene (N), (Stickstoff).

Workers suffer much from the gas smell. PW states that the ANILIN WERK is most important to the war-effort.

Ueber den Einfluss der Zentrifugalkraft auf chemische Systeme.

Von

G. Bredig.

(Mit 3 Figuren im Text.)

Einleitung.

Die Frage, ob durch den Einfluss äusserer Kräfte, wie z. B. durch die Gravitation, sich in einem ursprünglich homogenen Gemenge Konzentrationsverschiedenheiten in der Richtung dieser Kräfte ausbilden, ist bereits im Anfange dieses Jahrhunderts diskutiert worden. So stellte bereits Gay-Lussac[1]) in den Kellern der Pariser Sternwarte Versuche darüber an, ob eine Salzlösung in einer vertikalen 2 m langen Säule unter dem Einfluss der Schwerkraft am unteren Ende der Säule eine andere Konzentration annehme, als am oberen Ende. Er erhielt ein negatives Resultat, was nach den neueren Berechnungen von Gouy und Chaperon[2]) auch verständlich wird, da diese Autoren thermodynamisch den Einfluss der Gravitation auf die Konzentration aus der Änderung der Dichte mit der Konzentration zu berechnen vermögen und denselben so klein finden, dass seine experimentelle Feststellung schwerlich ausführbar ist.

Die Theorie solcher Systeme ist bereits mehrfach, von J. W. Gibbs[3]), Gouy und Chaperon[4]), P. Duhem[5]), van der Waals[6]) und anderen gegeben worden.

Nun hat aber unlängst Herr Th. des Coudres in einer interessanten Abhandlung[7]) beiläufig darauf hingewiesen, dass man die Betrachtungen über den Einfluss der Schwere auf die Konzentration der Lö-

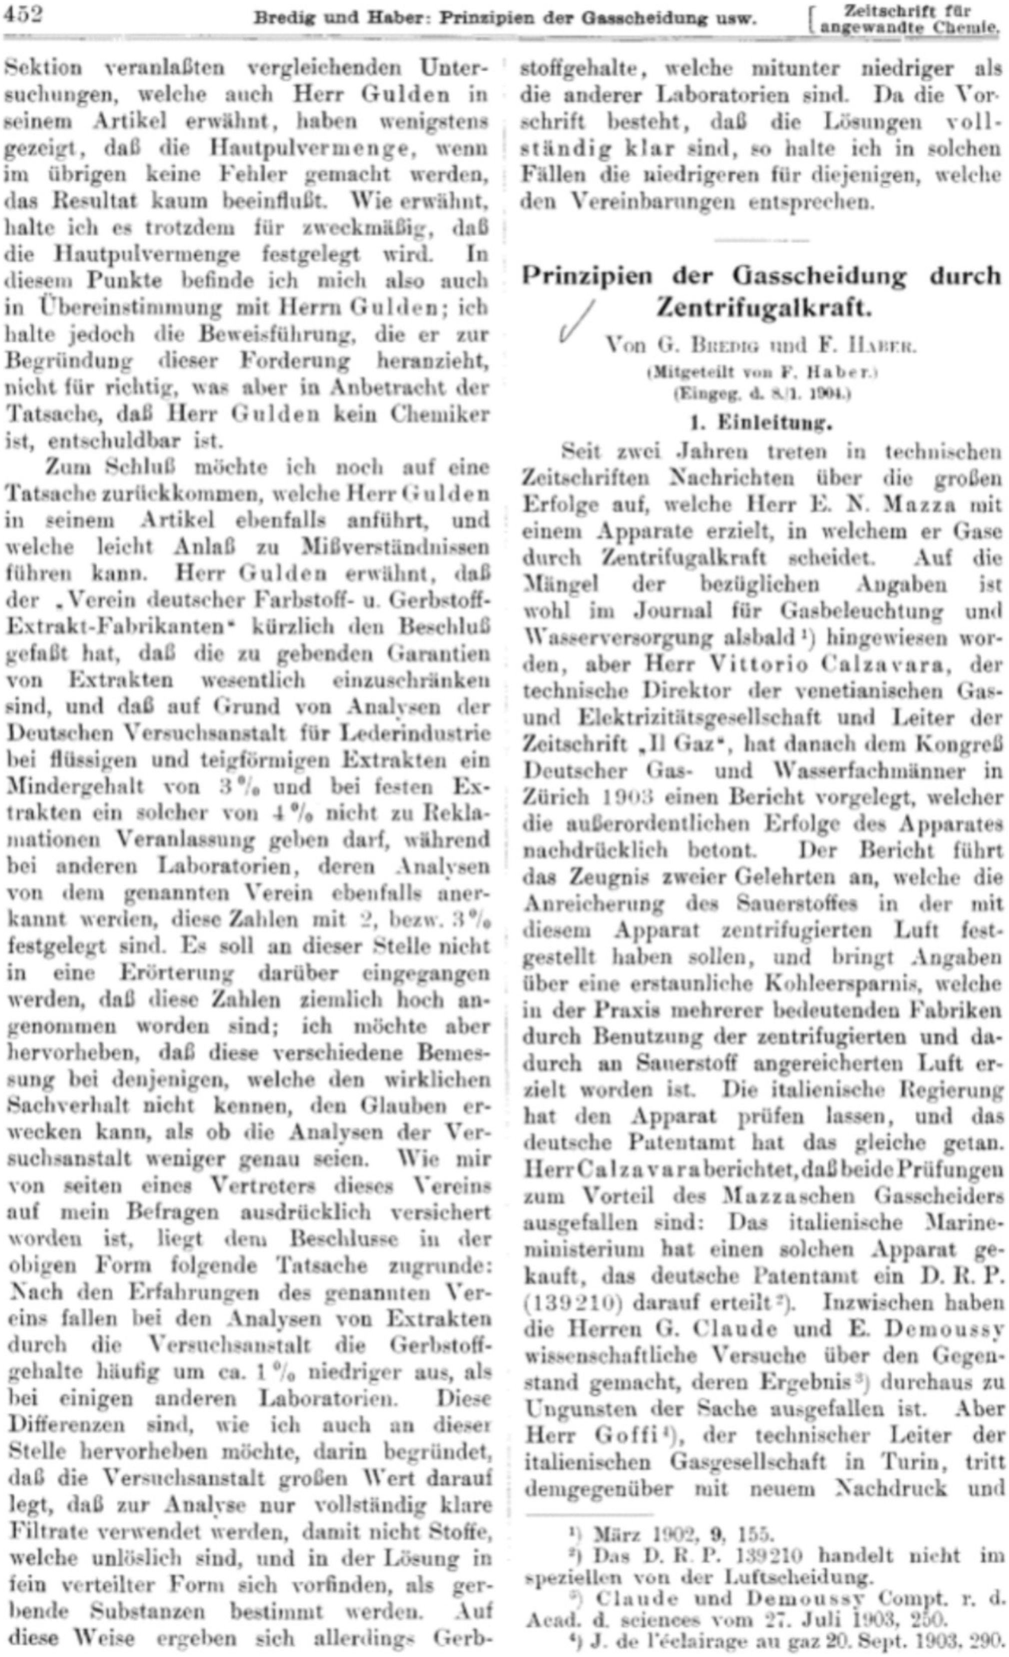
[By the 1930s and early 1940s, gas centrifuges were being produced, improved, and tested by several groups in the German-speaking world. They were demonstrated with various gaseous mixtures for unclassified publications, but they were most seriously pursued for more secretive work on uranium isotope separation.]



452 Bredig und Haber: Prinzipien der Gasscheidung usw. [Zeitschrift für angewandte Chemie.

Sektion veranlaßten vergleichenden Untersuchungen, welche auch Herr Gulden in seinem Artikel erwähnt, haben wenigstens gezeigt, daß die Hautpulvermenge, wenn im übrigen keine Fehler gemacht werden, das Resultat kaum beeinflußt. Wie erwähnt, halte ich es trotzdem für zweckmäßig, daß die Hautpulvermenge festgelegt wird. In diesem Punkte befinde ich mich also auch in Übereinstimmung mit Herrn Gulden; ich halte jedoch die Beweisführung, die er zur Begründung dieser Forderung heranzieht, nicht für richtig, was aber in Anbetracht der Tatsache, daß Herr Gulden kein Chemiker ist, entschuldbar ist.

Zum Schluß möchte ich noch auf eine Tatsache zurückkommen, welche Herr Gulden in seinem Artikel ebenfalls anführt, und welche leicht Anlaß zu Mißverständnissen führen kann. Herr Gulden erwähnt, daß der „Verein deutscher Farbstoff- u. Gerbstoff-Extrakt-Fabrikanten" kürzlich den Beschluß gefaßt hat, daß die zu gebenden Garantien von Extrakten wesentlich einzuschränken sind, und daß auf Grund von Analysen der Deutschen Versuchsanstalt für Lederindustrie bei flüssigen und teigförmigen Extrakten ein Mindergehalt von 3% und bei festen Extrakten ein solcher von 4% nicht zu Reklamationen Veranlassung geben darf, während bei anderen Laboratorien, deren Analysen von dem genannten Verein ebenfalls anerkannt werden, diese Zahlen mit 2, bezw. 3% festgelegt sind. Es soll an dieser Stelle nicht in eine Erörterung darüber eingegangen werden, daß diese Zahlen ziemlich hoch angenommen worden sind; ich möchte aber hervorheben, daß diese verschiedene Bemessung bei denjenigen, welche den wirklichen Sachverhalt nicht kennen, den Glauben erwecken kann, als ob die Analysen der Versuchsanstalt weniger genau seien. Wie mir von seiten eines Vertreters dieses Vereins auf mein Befragen ausdrücklich versichert worden ist, liegt dem Beschlusse in der obigen Form folgende Tatsache zugrunde: Nach den Erfahrungen des genannten Vereins fallen bei den Analysen von Extrakten durch die Versuchsanstalt die Gerbstoffgehalte häufig um ca. 1% niedriger aus, als bei einigen anderen Laboratorien. Diese Differenzen sind, wie ich auch an dieser Stelle hervorheben möchte, darin begründet, daß die Versuchsanstalt großen Wert darauf legt, daß zur Analyse nur vollständig klare Filtrate verwendet werden, damit nicht Stoffe, welche unlöslich sind, und in der Lösung in fein verteilter Form sich vorfinden, als gerbende Substanzen bestimmt werden. Auf diese Weise ergeben sich allerdings Gerbstoffgehalte, welche mitunter niedriger als die anderer Laboratorien sind. Da die Vorschrift besteht, daß die Lösungen vollständig klar sind, so halte ich in solchen Fällen die niedrigeren für diejenigen, welche den Vereinbarungen entsprechen.

Prinzipien der Gasscheidung durch Zentrifugalkraft.

Von G. Bredig und F. Haber.

(Mitgeteilt von F. Haber.)

(Eingeg. d. 8./1. 1904.)

1. Einleitung.

Seit zwei Jahren treten in technischen Zeitschriften Nachrichten über die großen Erfolge auf, welche Herr E. N. Mazza mit einem Apparate erzielt, in welchem er Gase durch Zentrifugalkraft scheidet. Auf die Mängel der bezüglichen Angaben ist wohl im Journal für Gasbeleuchtung und Wasserversorgung alsbald[1]) hingewiesen worden, aber Herr Vittorio Calzavara, der technische Direktor der venetianischen Gas- und Elektrizitätsgesellschaft und Leiter der Zeitschrift „Il Gaz", hat danach dem Kongreß Deutscher Gas- und Wasserfachmänner in Zürich 1903 einen Bericht vorgelegt, welcher die außerordentlichen Erfolge des Apparates nachdrücklich betont. Der Bericht führt das Zeugnis zweier Gelehrten an, welche die Anreicherung des Sauerstoffes in der mit diesem Apparat zentrifugierten Luft festgestellt haben sollen, und bringt Angaben über eine erstaunliche Kohleersparnis, welche in der Praxis mehrerer bedeutenden Fabriken durch Benutzung der zentrifugierten und dadurch an Sauerstoff angereicherten Luft erzielt worden ist. Die italienische Regierung hat den Apparat prüfen lassen, und das deutsche Patentamt hat das gleiche getan. Herr Calzavara berichtet, daß beide Prüfungen zum Vorteil des Mazzaschen Gasscheiders ausgefallen sind: Das italienische Marineministerium hat einen solchen Apparat gekauft, das deutsche Patentamt ein D. R. P. (139210) darauf erteilt[2]). Inzwischen haben die Herren G. Claude und E. Demoussy wissenschaftliche Versuche über den Gegenstand gemacht, deren Ergebnis[3]) durchaus zu Ungunsten der Sache ausgefallen ist. Aber Herr Goffi[4]), der technischer Leiter der italienischen Gasgesellschaft in Turin, tritt demgegenüber mit neuem Nachdruck und

Prospects for the separation of gas mixtures by centrifugation*)

*) Excerpt presented by *H. Hausen* at the conference of the VDI German Refrigeration Association in Frankfurt a. M. on 30 May 1938.

The prospects of gas separation in a centrifuge are investigated on the basis of a precise theory. The differential equations obtained are solved using a step-by-step method. According to the calculation, a satisfactory separation can only be expected in particularly favorable cases and with very small quantities. [...]

As early as 1895, *Bredig*³) tried to separate hydrogen and hydrogen iodide by centrifugation and observed a separation of about 2.8% after three hours in a centrifuge of about 42 cm diameter at 2300 rpm. In 1904, *Bredig* and *Haber*⁴) theoretically investigated the seemingly achievable separation effect by centrifugation and also estimated the time required.

Ergebnis

Die entwickelte Theorie bestätigt im wesentlichen die Richtigkeit der Berechnungen von *Bredig* und *Haber*4), wonach sich in einer Zentrifuge im allgemeinen nur mäßige Anreicherungen erzielen lassen, stets aber nur sehr geringe Gasmengen in der Zeiteinheit zerlegt werden können. Nur in Fällen, wie bei CO_2-H_2- oder Benzol-Luft-Gemischen, in denen der Molekulargewichtsunterschied der Bestandteile groß ist, kann man eine weitergehende Zerlegung erwarten. Bei der höchsten heute erreichten Umfangsgeschwindigkeit von fast 600 m/s läßt sich z. B. Benzol in Luft auf etwa 16% anreichern, wenn der Anfangsgehalt 1% beträgt. Bei weiterer Steigerung der Umfangsgeschwindigkeit würde sich dieser Wert sehr rasch erhöhen, so daß man oberhalb 1000 m/s praktisch reines Benzol gewinnen könnte. Hingegen erscheint selbst bei dieser hohen Umfangsgeschwindigkeit eine Zerlegung von O_2-N_2-Gemischen als praktisch aussichtslos.

Die Hauptschwierigkeit besteht aber darin, daß sich in einer Zentrifuge nur sehr geringe Mengen verarbeiten lassen. Nach der entwickelten Theorie kann durch eine Zentrifuge von 1 m axialer Länge stündliche nur etwa 1 m^3 des Gemisches hindurchströmen, wenn nicht die Anreicherung erheblich zurückgehen soll.

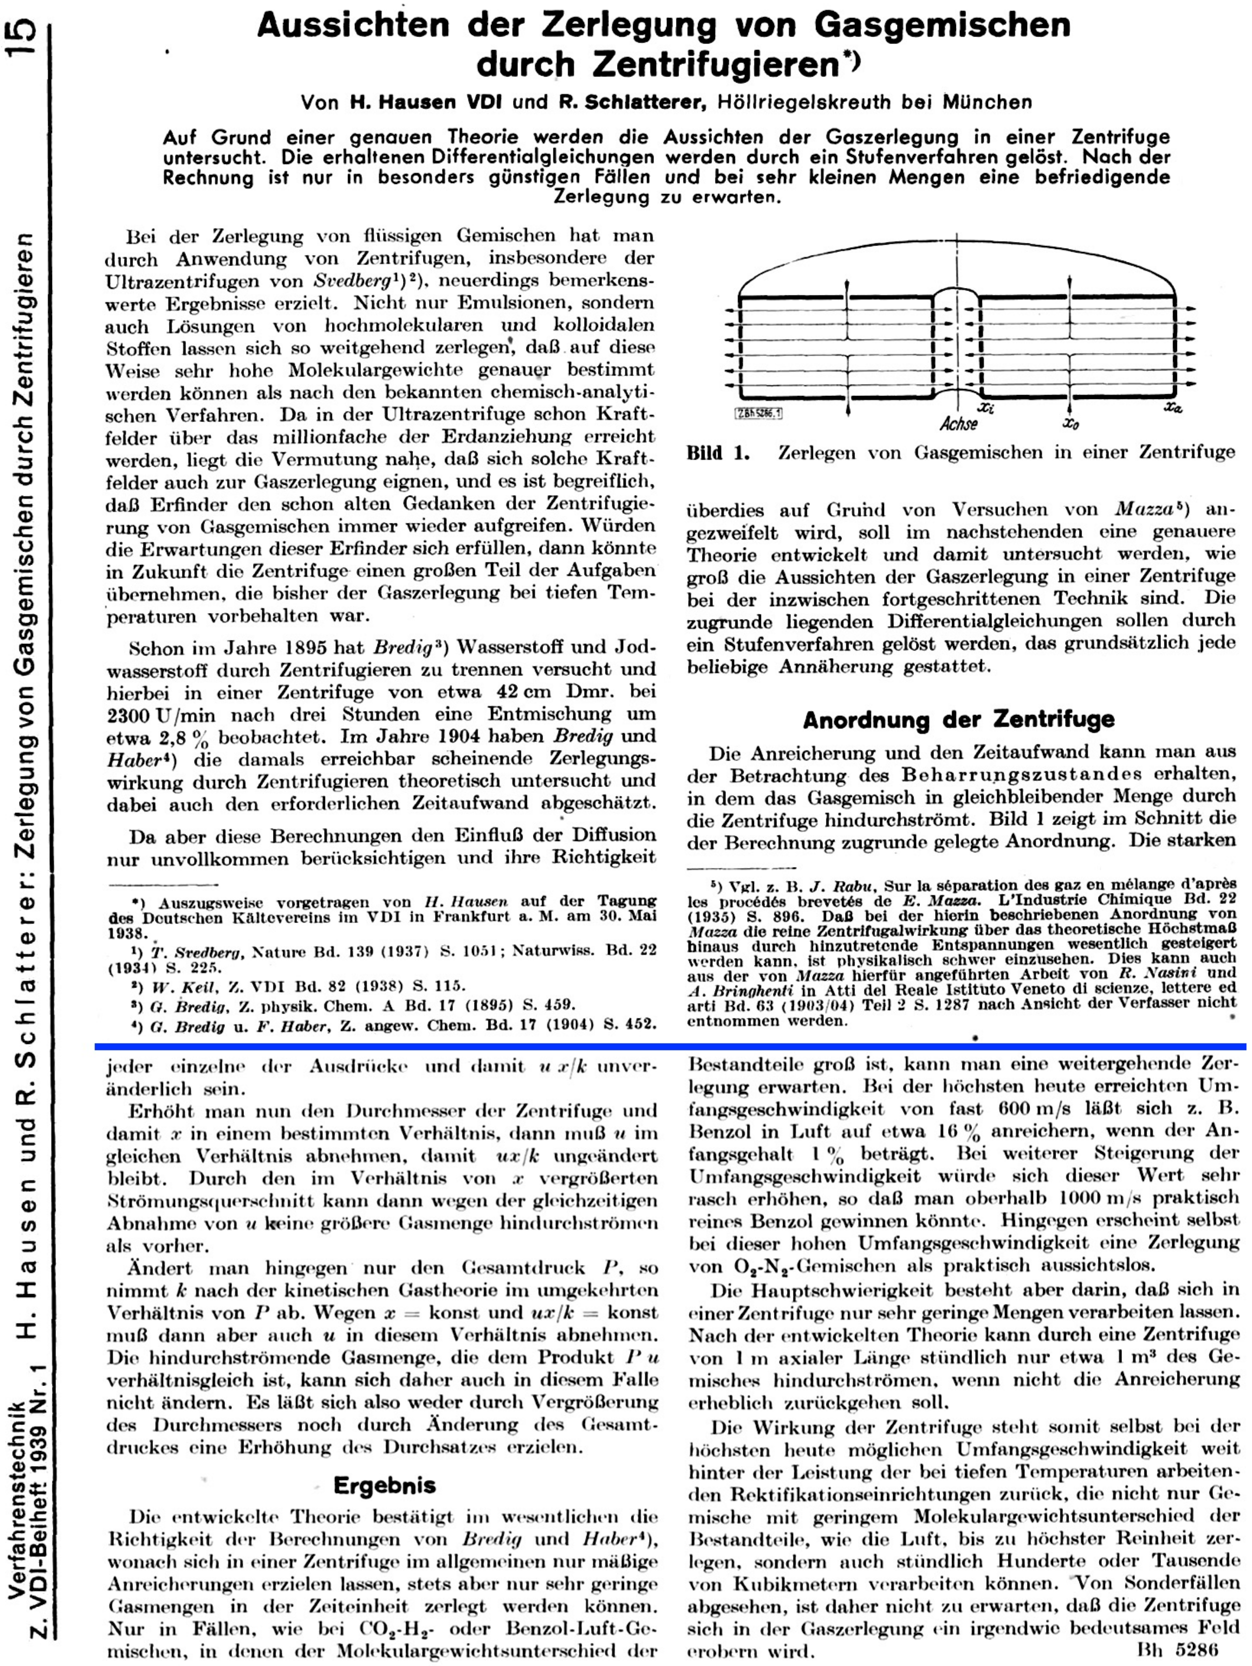
Die Wirkung der Zentrifuge steht somit selbst bei der höchsten heute möglichen Umfangsgeschwindigkeit weit hinter der Leistung der bei tiefen Temperaturen arbeitenden Rektifikationseinrichtungen zurück, die nicht nur Gemische mit geringem Molekulargewichtsunterschied der Bestandteile, wie die Luft, bis zu höchster Reinheit zerlegen, sondern auch stündlich Hunderte oder Tausende von Kubikmetern verarbeiten können. Von Sonderfällen abgesehen, ist daher nicht zu erwarten, daß die Zentrifuge sich in der Gaszerlegung ein irgendwie bedeutsames Feld erobern wird.

Result

The theory developed essentially confirms the correctness of the calculations of *Bredig* and *Haber*4), according to which only moderate enrichments can generally be achieved in a centrifuge, but only very small quantities of gas can always be separated in the time unit. Only in cases such as CO_2-H_2 or benzene-air mixtures, in which the molecular weight difference of the components is large, can further separation be expected. At the highest peripheral speed of almost 600 m/s achieved today, benzene in air, for example, can be enriched to around 16% if the initial content is 1%. If the circumferential speed is increased further, this value would increase very quickly, so that above 1000 m/s practically pure benzene could be obtained. On the other hand, even at this high peripheral speed, the separation of O_2-N_2 mixtures appears to be practically hopeless.

The main difficulty, however, is that only very small quantities can be processed in a centrifuge. According to the theory developed, only about 1 m^3 per hour of the mixture can flow through a centrifuge with an axial length of 1 m if the enrichment is not to be considerably reduced.

Even at the highest peripheral speed possible today, the effect of the centrifuge is therefore far behind the performance of rectification equipment operating at low temperatures, which can not only break down mixtures with a small difference in molecular weight of the components, such as air, to the highest purity, but can also process hundreds or thousands of cubic meters per hour. Apart from special cases, it is therefore unlikely that the centrifuge will conquer any significant field in gas separation.



Aussichten der Zerlegung von Gasgemischen durch Zentrifugieren*)

Von **H. Hausen VDI** und **R. Schlatterer**, Höllriegelskreuth bei München

Auf Grund einer genauen Theorie werden die Aussichten der Gaszerlegung in einer Zentrifuge untersucht. Die erhaltenen Differentialgleichungen werden durch ein Stufenverfahren gelöst. Nach der Rechnung ist nur in besonders günstigen Fällen und bei sehr kleinen Mengen eine befriedigende Zerlegung zu erwarten.

Bei der Zerlegung von flüssigen Gemischen hat man durch Anwendung von Zentrifugen, insbesondere der Ultrazentrifugen von *Svedberg*1)2), neuerdings bemerkenswerte Ergebnisse erzielt. Nicht nur Emulsionen, sondern auch Lösungen von hochmolekularen und kolloidalen Stoffen lassen sich so weitgehend zerlegen, daß auf diese Weise sehr hohe Molekulargewichte genauer bestimmt werden können als nach den bekannten chemisch-analytischen Verfahren. Da in der Ultrazentrifuge schon Kraftfelder über das millionfache der Erdanziehung erreicht werden, liegt die Vermutung nahe, daß sich solche Kraftfelder auch zur Gaszerlegung eignen, und es ist begreiflich, daß Erfinder den schon alten Gedanken der Zentrifugierung von Gasgemischen immer wieder aufgreifen. Würden die Erwartungen dieser Erfinder sich erfüllen, dann könnte in Zukunft die Zentrifuge einen großen Teil der Aufgaben übernehmen, die bisher der Gaszerlegung bei tiefen Temperaturen vorbehalten war.

Schon im Jahre 1895 hat *Bredig*3) Wasserstoff und Jodwasserstoff durch Zentrifugieren zu trennen versucht und hierbei in einer Zentrifuge von etwa 42 cm Dmr. bei 2300 U/min nach drei Stunden eine Entmischung um etwa 2,8 % beobachtet. Im Jahre 1904 haben *Bredig* und *Haber*4) die damals erreichbar scheinende Zerlegungswirkung durch Zentrifugieren theoretisch untersucht und dabei auch den erforderlichen Zeitaufwand abgeschätzt.

Da aber diese Berechnungen den Einfluß der Diffusion nur unvollkommen berücksichtigen und ihre Richtigkeit überdies auf Grund von Versuchen von *Mazza*5) angezweifelt wird, soll im nachstehenden eine genauere Theorie entwickelt und damit untersucht werden, wie groß die Aussichten der Gaszerlegung in einer Zentrifuge bei der inzwischen fortgeschrittenen Technik sind. Die zugrunde liegenden Differentialgleichungen sollen durch ein Stufenverfahren gelöst werden, das grundsätzlich jede beliebige Annäherung gestattet.

5) Vgl. z. B. *J. Rabu*, Sur la séparation des gaz en mélange d'après les procédés brevetés de *E. Mazza*. L'Industrie Chimique Bd. 22 (1935) S. 896. Daß bei der hierin beschriebenen Anordnung von *Mazza* die reine Zentrifugalwirkung über das theoretische Höchstmaß hinaus durch hinzutretende Entspannungen wesentlich gesteigert werden kann, ist physikalisch schwer einzusehen. Dies kann auch aus der von *Mazza* hierfür angeführten Arbeit von *R. Nasini* und *A. Bringhenti* in Atti del Reale Istituto Veneto di scienze, lettere ed arti Bd. 63 (1903/04) Teil 2 S. 1287 nach Ansicht der Verfasser nicht entnommen werden.

---

jeder einzelne der Ausdrücke und damit $u\,x/k$ unveränderlich sein.

Erhöht man nun den Durchmesser der Zentrifuge und damit x in einem bestimmten Verhältnis, dann muß u im gleichen Verhältnis abnehmen, damit ux/k ungeändert bleibt. Durch den im Verhältnis von x vergrößerten Strömungsquerschnitt kann dann wegen der gleichzeitigen Abnahme von u keine größere Gasmenge hindurchströmen als vorher.

Ändert man hingegen nur den Gesamtdruck P, so nimmt k nach der kinetischen Gastheorie im umgekehrten Verhältnis von P ab. Wegen $x =$ konst und $ux/k =$ konst muß dann aber auch u in diesem Verhältnis abnehmen. Die hindurchströmende Gasmenge, die dem Produkt $P\,u$ verhältnisgleich ist, kann sich daher auch in diesem Falle nicht ändern. Es läßt sich also weder durch Vergrößerung des Durchmessers noch durch Änderung des Gesamtdruckes eine Erhöhung des Durchsatzes erzielen.

Ergebnis

Die entwickelte Theorie bestätigt im wesentlichen die Richtigkeit der Berechnungen von *Bredig* und *Haber*4), wonach sich in einer Zentrifuge im allgemeinen nur mäßige Anreicherungen erzielen lassen, stets aber nur sehr geringe Gasmengen in der Zeiteinheit zerlegt werden können. Nur in Fällen, wie bei CO_2-H_2- oder Benzol-Luft-Gemischen, in denen der Molekulargewichtsunterschied der Bestandteile groß ist, kann man eine weitergehende Zerlegung erwarten. Bei der höchsten heute erreichten Umfangsgeschwindigkeit von fast 600 m/s läßt sich z. B. Benzol in Luft auf etwa 16 % anreichern, wenn der Anfangsgehalt 1 % beträgt. Bei weiterer Steigerung der Umfangsgeschwindigkeit würde sich dieser Wert sehr rasch erhöhen, so daß man oberhalb 1000 m/s praktisch reines Benzol gewinnen könnte. Hingegen erscheint selbst bei dieser hohen Umfangsgeschwindigkeit eine Zerlegung von O_2-N_2-Gemischen als praktisch aussichtslos.

Die Hauptschwierigkeit besteht aber darin, daß sich in einer Zentrifuge nur sehr geringe Mengen verarbeiten lassen. Nach der entwickelten Theorie kann durch eine Zentrifuge von 1 m axialer Länge stündlich nur etwa 1 m³ des Gemisches hindurchströmen, wenn nicht die Anreicherung erheblich zurückgehen soll.

Zerlegung von Gasgemischen in einer Zentrifuge mit Gegenstromwirkung

Von **H. Hausen VDI**, Höllriegelskreuth bei München

In einer Zentrifuge mit Gegenstromwirkung läßt sich grundsätzlich ein Gasgemisch beliebig weitgehend zerlegen. Die Vorgänge des Stoffaustausches in derartigen Zentrifugen lassen sich rechnerisch erfassen. Danach zerlegt eine Gegenstromzentrifuge von 2,5 m Höhe im günstigsten Falle eine sehr geringe Luftmenge in 99,7%igen Sauerstoff und 99,7%igen Stickstoff. Schon bei 1 l stündlich zerlegter Luftmenge geht die Reinheit auf 98% zurück. Der äußerst geringen Mengenleistung wegen ist demnach die Gegenstromzentrifuge der Gaszerlegung durch Rektifikation weit unterlegen. Nach Überwindung der technischen Schwierigkeiten wird sie voraussichtlich für die Isotopentrennung und für Laboratoriumszwecke Bedeutung gewinnen.

In einer früheren Arbeit[1]) haben *R. Schlatterer* und der Verfasser gezeigt, daß Gasgemische sich in einer einfachen Zentrifuge nur sehr unvollkommen zerlegen lassen. Die überraschenden Erfolge, die *Clusius*[2]) beim Thermodiffusionsverfahren durch Verbindung mit dem Gegenstromprinzip erzielt hat, brachten mich jedoch gegen Ende des Jahres 1938 auf den Gedanken, daß sich auch in einer Zentrifuge die Reinheit der Zerlegungsprodukte beliebig steigern lassen müsse, wenn man die Gegenstromwirkung zu Hilfe nimmt[3]). Die Richtigkeit dieses Gedankens konnte ich durch noch nicht veröffentlichte theoretische Überlegungen und Berechnungen bestätigen.

Unabhängig hiervon haben neuerdings *Martin* und *Kuhn*[4]) eine Theorie der Zentrifugierung von Gasgemischen unter Gegenstromwirkung veröffentlicht. Die Grundgedanken dieser Theorie sind großenteils ähnlich wie die meiner genannten früheren Berechnungen. In der Art der Durchführung, in der Wahl der als zulässig angesehenen Vernachlässigungen und in den Endgleichungen bestehen jedoch wesentliche Unterschiede. Überdies geht mein Berechnungsverfahren dadurch über die Überlegungen von *Martin* und *Kuhn* hinaus, daß es durchweg für beliebige Konzentrationen des Ausgangsgemisches gilt und die verschiedenen Geschwindigkeiten der in der Zentrifuge auf- und absteigenden Gasströme berücksichtigt. Hierdurch läßt sich auch eingehender zeigen, wie die erzielbaren Reinheiten der Enderzeugnisse von der stündlich zerlegten Menge abhängen. Die Grundlagen und Ergebnisse meiner Berechnungen werden im folgenden erörtert.

Anordnung und Wirkung des Gegenstromes in einer Zentrifuge

Bild 1 stellt einen axialen Schnitt durch eine Gaszentrifuge mit Gegenstromwirkung dar. Die an sich beliebige Lage der Achse sei senkrecht angenommen. Das äußerliche Kennzeichen einer Zentrifuge mit Gegenstromwirkung besteht darin, daß die Länge in axialer Richtung groß gegen den äußeren Durchmesser ist. Durch die zylindrische Außenwand vom Halbmesser r_a, die Innenwand vom Halbmesser r_i und durch die obere und untere Stirnwand wird ein ringförmiger Schacht gebildet, in dem das zu zerlegende Gas wie folgt umläuft: In den inneren Teilen des Schachtes strömt das Gas langsam nach oben, in den äußeren Teilen nach unten, so daß zwei sich berührende Ströme entgegengesetzter Richtung entstehen. Oben und unten kehrt die Stromrichtung um. Die beschriebene Gegenstrombewegung soll so langsam sein, daß sie stets laminar bleibt, damit nirgends Teilchen verschiedener Zusammensetzung durch Turbulenz vermischt werden können. Die verschiedenen Möglichkeiten der Anregung des Gegenstromes werden später besprochen.

Bild 1. Schnitt durch eine Gegenstrom-Zentrifuge

Die erhöhte Trennwirkung des Gegenstromes erhellt aus folgender Überlegung. Dreht sich die Zentrifuge mit hoher Drehzahl, dann sucht sich unter der Einwirkung des Zentrifugalfeldes in jeder Höhe der Zentrifuge ein Gleichgewicht einzustellen, bei dem die äußeren Gasteilchen einen etwas höheren Gehalt am schwereren Bestandteil haben als die inneren Teilchen. Der Unterschied des Gehaltes an der Innen- und Außenwand entpricht hierbei etwa der Trennwirkung einer einfachen Zentrifuge[1]). Da aber die inneren Teilchen mit dem geringeren Gehalt sich nach oben bewegen und am obersten Ende umkehren, beginnt bald auch der Gehalt im Abwärtsstrom sich von oben her zu verringern. Auch mit diesem Abwärtsstrom suchen sich nun weiterhin aufwärts strömende Teilchen unter der Wirkung der Zentrifugalkraft ins Gleichgewicht zu setzen, so daß auch deren Gehalt geringer wird als nach der ersten Gleichgewichtseinstellung. Durch den beschriebenen Vorgang wird somit am oberen Ende der Zentrifuge eine sich selbst mehr und mehr verstärkende Abnahme des Gehaltes am schwereren Bestandteil eingeleitet. Umgekehrt tritt am untersten Ende der Zentrifuge unter Vertauschung der Rollen des Auf- und Abwärtsstromes eine wachsende Erhöhung des Gehaltes am schwereren Bestandteil auf. Da diese Änderungen sich allmählich nach den übrigen Teilen der Zentrifuge fortpflanzen, nimmt im Beharrungszustand der Gehalt am schwereren Bestandteil in der ganzen Zentrifuge stetig von unten nach oben ab. Daß dieser Zustand dauernd bestehen kann, zeigt noch genauer folgende Überlegung: Jedes aufwärts strömende Teilchen, das sich in einer bestimmten Höhe mit dem Abwärtsstrom so weit als möglich ins Gleichgewicht gesetzt hat, wird auf seinem weiteren Wege Teilchen des Abwärtsstroms mit immer geringerem Gehalt begegnen. Indem es sich auch mit diesen ins Gleichgewicht zu setzen sucht, muß sein eigener Gehalt am schwereren Bestandteil auf dem Weg nach oben ständig abnehmen. Umgekehrt muß der Gehalt eines Teilchens des Abwärtsstromes auf dem Weg nach unten immer mehr zunehmen. Denn auch ein solches Teilchen begegnet auf seinem Weg Teilchen des Aufwärtsstromes von immer höherem Gehalt und sucht sich mit diesen ins Gleichgewicht zu setzen.

Die Richtigkeit dieses Gedankens konnte ich durch noch nicht veröffentlichte theoretische Überlegungen und Berechnungen bestätigen.

Separation of gas mixtures in a centrifuge with countercurrent action

In principle, a gas mixture can be separated to any extent in a countercurrent centrifuge. The processes of mass transfer in such centrifuges can be calculated. According to this, a countercurrent centrifuge with a height of 2.5 m separates a very small amount of air into 99.7% oxygen and 99.7% nitrogen in the best case. The purity drops to 98% with just 1 liter of air separated per hour. The countercurrent centrifuge is therefore far inferior to gas separation by rectification due to its extremely low output. Once the technical difficulties have been overcome, it will probably gain importance for isotope separation and for laboratory purposes.

In an earlier work[1]) *R. Schlatterer* and the author showed that gas mixtures can only be very imperfectly separated in a simple centrifuge. However, the surprising successes achieved by *Clusius*[2]) in the thermodiffusion process in combination with the countercurrent principle gave me the idea towards the end of 1938 that the purity of the separation products in a centrifuge should also be able to be increased at will if the countercurrent effect is used[3]). I was able to confirm the correctness of this idea through theoretical considerations and calculations that had not yet been published.

Unabhängig hiervon haben neuerdings *Martin* und *Kuhn*4)) eine Theorie der Zentrifugierung von Gasgemischen unter Gegenstromwirkung veröffentlicht. Die Grundgedanken dieser Theorie sind großenteils ähnlich wie die meiner genannten früheren Berechnungen. In der Art der Durchführung, in der Wahl der als zulässig angesehenen Vernachlässigungen und in den Endgleichungen bestehen jedoch wesentliche Unterschiede. Überdies geht mein Berechnungsverfahren dadurch über die Überlegungen von *Martin* und *Kuhn* hinaus, daß es durchweg für beliebige Konzentrationen des Ausgangsgemisches gilt und die verschiedenen Geschwindigkeiten der in der Zentrifuge auf- und absteigenden Gasströme berücksichtigt. Independently of this, *Martin* and *Kuhn*4) have recently published a theory of the centrifugation of gas mixtures under countercurrent action. The basic ideas of this theory are largely similar to those of my earlier calculations. However, there are significant differences in the way the calculations are carried out, in the choice of neglect considered permissible and in the final equations. In addition, my calculation method goes beyond the considerations of *Martin* and *Kuhn* in that it is valid for any concentration of the initial mixture and takes into account the different velocities of the gas flows ascending and descending in the centrifuge. This also makes it possible to show in more detail how the achievable purities of the end products depend on the quantity separated per hour. The principles and results of my calculations are discussed below.

Hausen, H.
Verfahrenstechnik, Z.V.D.I. 1942, No. 4, p 93-102

Separation of Gas Mixtures in a Centrifuge with Counter current action. Develops theory for calculating height of centrifuge to obtain a desired degree of separation with a given rate of feed of gas mixture. His examples are to the separation of air which has been of interest in blowing blast furnaces with higher concentrations of oxygen than in air. He says one would not separate air in a centrifuge because of the cheaper distillation process. Says that O_2-N_2 in centrifuge shows separating factor 30 times that for thermal diffusion. Quotes Martin and Kuhn as saying that the centrifuge has a much higher energy efficiency than thermal diffusion.

Verfahren und Vorrichtung zur Zerlegung von Gas- und Flüssigkeitsgemischen in Zentrifugen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 18. Juni 1939 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 26. Juli 1951
Patenterteilung bekanntgemacht am 7. Februar 1952

Es hat bisher nicht an Versuchen gefehlt, Gasgemische durch Zentrifugieren zu zerlegen. Ein brauchbares Ergebnis konnte jedoch mit diesen Verfahren nicht erzielt werden, weil die Trennwirkung der bekannten Zentrifugierverfahren verhältnismäßig gering ist. Auch theoretisch läßt sich nachweisen, daß die Zerlegungswirkung einer nach den bekannten Verfahren betriebenen Zentrifuge selbst bei den höchsten heute möglichen Umfangsgeschwindigkeiten und bei Gemischen mit großen Unterschieden im Molekulargewicht nur sehr gering ist.

Nach der vorliegenden Erfindung läßt sich aber der an sich kleine, durch Zentrifugalwirkung erzielbare Trenneffekt dadurch zu größerer Wirkung bringen, daß man ihn durch Gegenstromführung der Gase verstärkt. Eine solche Verstärkung durch Gegenstrom ist z. B. bei der Rektifikation bekannt. Die nur geringe Zerlegungswirkung eines einzelnen Rektifikationsbodens wird dadurch vervielfacht, daß man eine große Zahl von solchen Böden übereinander anordnet und Flüssigkeit und Dampf im Gegenstrom führt. Ebenso läßt sich grundsätzlich die Trennwirkung einer Zentrifuge dadurch verbessern, daß die Gase verschiedener Zusammensetzung im Gegenstrom und in ähnlicher Weise wie z. B. bei den bekannten Gaszerlegungsverfahren durch Thermodiffusion im wesentlichen laminar geführt werden. An jeder Berührungsstelle der beiden Gasströme ändert sich ihre Zusammensetzung durch die Zentrifugalwirkung nur wenig. Die Addition dieser kleinen Wirkungen durch das Gegenstromprinzip gestattet aber, ebenso wie bei der Rektifikation, die Zerlegung grundsätzlich bis zu beliebiger Reinheit beider Bestandteile zu treiben.

Im folgenden wird die Arbeitsweise an Hand eines Ausführungsbeispiels näher erläutert. Zur Erzeugung des Gegenstromes wird beispielsweise die Schwerkraft benutzt. Am einfachsten läßt sich diese Arbeitsweise in einer sehr hoch gebauten Zentrifuge mit senkrechter Welle verwirklichen, wie sie in Abb. 1 dargestellt ist.

Abb. 1 ist eine schematische Darstellung einer zur Ausführung des Verfahrens geeigneten Zentrifuge. Der mit der Hohlwelle 3 rotierende Zentrifugenkörper ist mit 4 bezeichnet. 1 und 2 sind die Stellen, an welchen das zerlegte Gas abgeführt wird, während man das zu trennende Gemisch bei 5 einführt.

Abb. 2 ist ein Schnitt senkrecht zur Rotationsachse einer besonderen Ausführungsform der in Abb. 1 dargestellten Zentrifuge.

Abb. 3 stellt einen Schnitt parallel zur Rotationsachse einer zur Durchführung des Verfahrens geeigneten Zentrifuge dar.

Durch die Wirkung der Zentrifugalkraft tritt in jedem waagerechten Querschnitt eine Zerlegung in dem Sinne ein, daß sich außen der Gehalt am schwereren, innen am leichteren Bestandteil anreichert. Infolge der Schwerkraft haben aber die außen befindlichen schwereren Gase das Bestreben nach abwärts zu sinken, die innen befindlichen leichteren Gase hingegen aufzusteigen, so daß sich neben der durch die Zentrifugalkraft bewirkten Trennung zwei gegeneinandergerichtete senkrechte Konvektionsströme ausbilden. Diese gegeneinandergerichteten Ströme haben folgende Wirkung: Hat sich im Querschnitt *a-a* das Zentrifugalgleichgewicht eingestellt, so begegnet das hierdurch etwas leichter gewordene, innen strömende Gas im Querschnitt *b-b* einem außen nach unten strömenden Gas, das am schwereren Bestandteil noch nicht so stark angereichert ist wie das Gas im äußeren Teil vom Querschnitt *a-a*. Wenn daher in dem höheren Querschnitt wieder angenähert Zentrifugalgleichgewicht erreicht wird, so muß das aufsteigende, leichtere Gas erneut etwas von dem schwereren Bestandteil abgeben und etwas von dem leichteren Bestandteil aufnehmen. Das innen aufsteigende Gas wird sich also auf seinem Weg nach oben immer mehr an dem leichteren Bestandteil anreichern. Umgekehrt muß aus dem gleichen Grunde das außen nach abwärts sinkende Gas von Querschnitt zu Querschnitt an dem schwereren Bestandteil immer reicher werden. Im Beharrungszustand kann daher an dem oberen Ende der Zentrifuge bei 1 der leichtere Bestandteil, am unteren Ende der Zentrifuge bei 2 der schwerere Bestandteil in um so größerer Reinheit entnommen werden, je höher die Zentrifuge ist. Man wird daher der Zentrifuge eine große axiale Länge im Verhältnis zum Durchmesser geben und für dieses Verhältnis mindestens die Zahl 5 wählen.

Am oberen Ende der Zentrifuge wendet sich ein Teil des nach oben gerichteten Gasstromes um und bewegt sich dann außen wieder nach abwärts. Dieser Umkehr entspricht in einer Rektifikationssäule die Erzeugung von Rücklaufflüssigkeit aus den aufsteigenden Dämpfen. Ähnliches gilt für die Umkehr der Strömung am unteren Ende. Das unzerlegte Gemisch führt man zweckmäßig innen an derjenigen Stelle zu, an der das aufwärts strömende Gas dieselbe Zusammensetzung wie das unzerlegte Gas hat.

Zur Erzielung bestimmter Reinheitsgrade der Fraktionen ist es angebracht, die Geschwindigkeit des Auf- und Abwärtsströmens der Gase innerhalb geeigneter Grenzen zu halten, damit die Gase in jedem Querschnitt die richtige Zeit zur Verfügung haben, sich durch Diffusion mehr oder weniger ins Zentrifugalgleichgewicht zu setzen, was, wie alle Diffusionsvorgänge, eine gewisse Zeit beansprucht. Außerdem müssen Wirbel vermieden werden, die einen Teil der erzielten Zerlegung wieder rückgängig machen würden. Die Konvektionsströmung muß also langsam und vollständig laminar erfolgen. Die in Frage kommende Geschwindigkeit des laminaren Gasstromes und die Diffusionsgeschwindigkeit können je nach den besonderen Verhältnissen sehr unterschiedliche Werte haben. Im allgemeinen wird die Diffusionsgeschwindigkeit in der Größenordnung von einigen Millimeter je Sekunde oder Zentimeter je Sekunde liegen, wobei unter Diffusionsgeschwindigkeit der Quotient aus der Diffusionskonstanten D (cm²/sec) und dem mittleren Diffusionsweg Δx (cm) zu verstehen ist. Hierbei bedeutet Δx die radiale Entfernung zwischen dem Kern der aufsteigenden und dem Kern der absteigenden Strömung. Die Geschwindigkeit des laminaren Gasstromes kann kleiner oder größer als die Diffusionsgeschwindigkeit sein. Steigt die Gasgeschwindigkeit über einen optimalen Wert, der etwa gleich $\frac{D}{\Delta x}\sqrt{2}$ ist, oder sinkt sie unter diesen Wert, so wird die Reinheit der Produkte kleiner. Eine zu hohe Gasgeschwindigkeit wird sich im allgemeinen nicht einstellen, weil der Druck in den äußeren Teilen der Zentrifuge wegen der höheren Dichte nach unten hin in stärkerem Maße zunimmt als in den inneren Teilen, und die so entstehenden Druckunterschiede der beschriebenen Wirkung der Schwerkraft mehr oder weniger entgegenwirken. Wenn aber die Geschwindigkeit ausnahmsweise zu groß wird, namentlich unter Mitwirkung der weiter unten beschriebenen Mittel zur Erzeugung des Gegenstromes, dann läßt sich gemäß der Erfindung eine Herabminderung der Geschwindigkeit z. B. dadurch erreichen, daß man den äußeren Durchmesser der Zentrifuge so klein wählt, daß die Wandreibung den Konvektionsstrom genügend abbremst. In den meisten Fällen wird es aber erwünscht sein, den Durchmesser größer zu wählen. Dann kann man nötigenfalls die Gasgeschwindigkeit dadurch verringern, daß man z. B. die Welle der Zentrifuge zur Verminderung des Einflusses der Schwerkraft nicht senkrecht, sondern schräg anordnet. Ferner läßt sich der Konvektionsstrom auch durch geeignete Einbauten abbremsen. Als Einbauten kommen z. B. senkrechte radiale Wände in Frage (Abb. 2), die zugleich dafür sorgen, daß die Winkelgeschwindigkeit des Gases nicht hinter der der Zentrifuge zurückbleibt, oder auch waagerechte oder konische Netze, Gaze, Tücher, gelochte Bleche u. dgl., die den Gasdurchtritt nach oben und unten erschweren. Die konische Form (Abb. 3) wird hierbei vorzuziehen sein, da hierdurch zwischen den einzelnen Lagen dieser Stoffe zusätzliche schädliche Konvektionsströme in radialer Richtung vermieden werden können.

Auch Einbauten, die die Gestalt ein- oder mehrgängiger Schraubenflächen haben, erweisen sich als günstig. Sie verringern die Konvektionsgeschwindigkeit nicht nur durch den verengten Querschnitt, sondern auch dadurch, daß ähnlich wie bei der schräg gestellten Zentrifuge nicht die ganze Schwerkraft, sondern nur eine Komponente in der Strömungsrichtung zur Wirkung kommt. Auch wird der Weg des Konvektionsstromes im Vergleich zur Höhe der Zentrifuge verlängert, so daß diese Anordnung einer höheren Zentrifuge mit senkrechter Strömungsrichtung gleichwertig ist. Die Erzeugende der Schraubenfläche kann gerade oder gekrümmt sein und mit der Drehachse einen beliebigen Winkel einschließen. Durch eine von der Achse aus schräg nach unten gerichtete Erzeugende lassen sich etwaige unerwünschte radiale Konvektionsströme vermeiden.

Außer Gewichtsunterschieden können grundsätzlich auch andere Mittel zur Anregung und Aufrechterhaltung oder unter Umständen auch zur Abbremsung des Gegenstromes herangezogen werden. In diesem Sinne können Temperaturunterschiede wirken, indem man z. B. die Gase im inneren Teil der Zentrifuge beheizt. Es wäre auch denkbar, den Impuls des eintretenden, noch unzerlegten Gasgemisches hierzu zu verwenden, was z. B. bei waagerechter Lagerung der Zentrifuge von Bedeutung sein könnte. Grundsätzlich läßt sich der Gegenstrom auch in entgegengesetzter Richtung des Beispiels durchführen, wobei der äußere Gasstrom sich aufwärts, der innere Gasstrom sich abwärts bewegt. In diesem Falle wird der leichtere Bestandteil am unteren, der schwerere Bestandteil am oberen Zentrifugenende gewonnen. Erzeugen läßt sich ein solcher umgekehrter Gegenstrom z. B. dadurch, daß man die Zentrifuge außen beheizt und innen kühlt. Vielleicht läßt sich auch schon die Tatsache, daß der Teil des frisch eintretenden Gases, der sofort in die äußeren Teile der Zentrifuge gelangt, sich durch adiabatische Verdichtung erwärmt und dadurch einen Auftrieb nach oben erfährt, unter Umständen zur Anregung des Gegenstromes in der umgekehrten Richtung mit ausnutzen.

Ergebnisse, wie sie sich nach der Erfindung erzielen lassen, werden in nachstehendem Vergleichsbeispiel dargestellt. Zugrunde gelegt wird eine Zentrifuge von 2 m Höhe, deren ringkreisförmiger Zentrifugenraum die lichten Abmessungen von 2 cm für den Durchmesser des inneren Zuführungsrohres und von 6 cm für den Mantel hat. Wenn man eine solche Zentrifuge mit der verhältnismäßig leicht zu erreichenden Umfangsgeschwindigkeit von 300 m/sec rotieren läßt, so können beide Komponenten eines 50%igen binären Isotopengemisches oder auch eines entsprechenden Gasgemisches ohne Anwendung des erfindungsgemäßen Gegenstromes von 50 auf 51 % angereichert werden. Bei Anwendung des erfindungsgemäßen Gegenstromes dagegen läßt sich eine Anreicherung von 50 auf 76 % erreichen.

Läßt man eine solche Zentrifuge mit der höchsten bisher bei Zentrifugen erreichten Umfangsgeschwindigkeit von 600 m/sec rotieren, so wird ohne Anwendung des erfindungsgemäßen Gegenstromes eine Anreicherung der Komponenten bis höchstens 53,4 % erreicht. Unter Benutzung des erfindungsgemäßen Gegenstromes dagegen läßt sich eine 99%ige Anreicherung erzielen.

Die vorstehenden Angaben sind das Ergebnis einer Näherungsrechnung. In der Praxis werden die Ergebnisse sowohl beim Arbeiten mit Gegenstrom als auch ohne Gegenstrom voraussichtlich etwas ungünstiger sein.

Das erfundene Verfahren ist nicht nur auf Gasgemische anwendbar, sondern kann in analoger Weise auch zur Trennung schwer zerlegbarer Flüssigkeiten verwendet werden. Es ist zwar bekannt, Emulsionen in Zentrifugen zu trennen; mit einer erfindungsgemäßen Zentrifuge lassen sich dagegen weit höhere Leistungen erzielen, z. B. die Trennung echter Lösungen oder kolloidaler Mischungen, was mit gewöhnlichen Zentrifugen nicht möglich ist.

PATENTANSPRÜCHE:

1. Verfahren zur Zerlegung von Gas- und Flüssigkeitsgemischen in Zentrifugen, dadurch gekennzeichnet, daß ein Kreisstrom als achsparalleler laminarer Gegenstrom geführt wird, wobei Zentrifugen angewendet werden, deren axiale Länge wesentlich größer ist als ihr äußerer Durchmesser und bei denen die Ableitung der Zerlegungsprodukte aus dem Läufer der Zentrifuge an Stellen erfolgt, welche in der Projektion auf die Welle gemessen, weit voneinander entfernt sind.

2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß der Gegenstrom durch die Schwerkraft bewirkt wird.

3. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß der Impuls des mit einer anfänglichen Geschwindigkeit eintretenden unzerlegten Gasgemisches zur Anregung und Aufrechterhaltung oder auch zur Abbremsung des Gegenstromes auf den günstigsten Wert herangezogen wird.

4. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß der Gegenstrom mit Hilfe einer in der Zentrifuge aufrechterhaltenen Temperaturdifferenz erzeugt wird.

5. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1, gekennzeichnet durch Einbauten zur Abbremsung der Geschwindigkeit des Gegenstromes, die vorzüglich aus radialen senkrechten Wänden oder trichterförmigen Netzen, gelochten Blechen oder Tucheinlagen bestehen.

6. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1, gekennzeichnet durch Einbauten, die die Gestalt ein- oder mehrgängiger Schraubenflächen haben.

7. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1 und 2, dadurch gekennzeichnet, daß zur Aufrechterhaltung einer günstigsten Geschwindigkeit des Gegenstromes die Rotationsachse schräg gegen die Richtung der Erdbeschleunigung eingestellt wird.

8. Zentrifuge zur Zerlegung von Gasgemischen, dadurch gekennzeichnet, daß das Verhältnis der axialen Länge zum Durchmesser der Zentrifuge größer als 5 ist.

14. SEPTEMBER 1953

DEUTSCHES PATENTAMT

PATENTSCHRIFT

Nr. 872 936

KLASSE 12e GRUPPE 3 05

G 415 IVb/12e

Dr.-Ing. Hellmuth Hausen, München-Solln und
Dr. Klaus Clusius, München
sind als Erfinder genannt worden

Gesellschaft für Linde's Eismaschinen A. G.,
Höllriegelskreuth bei München

Verfahren und Vorrichtung zur Zerlegung von Gasgemischen in Zentrifugen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 26. Oktober 1940 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 18. Oktober 1951
Patenterteilung bekanntgemacht am 6. August 1953

In der Patentschrift 833 487 ist ein Verfahren zur Zerlegung von flüssigen oder gasförmigen Gemischen durch Zentrifugieren beschrieben, bei dem eine besonders günstige Wirkung dadurch erzielt wird, daß das Gemisch innerhalb der Zentrifuge in einem laminaren Gegenstrom geführt wird. Der laminare Gegenstrom kann auf verschiedene Weise erzeugt werden, z. B. bei senkrecht stehender Zentrifuge durch die Schwerkraft. Er kann dabei durch Heizung verstärkt oder durch Neigung der Zentrifuge geschwächt werden. Der laminare Gegenstrom kann auch durch entsprechende Einbauten bei z. B. horizontaler Anordnung der Zentrifugenachse erzeugt werden.

Bei der Zerlegung von Gasgemischen läßt sich die Zerlegungswirkung einer solchen Zentrifuge dadurch wesentlich steigern, daß zusätzlich die Trennkräfte der Thermodiffusion angewendet werden. Der Unterschied im Vergleich zu der bereits in der Patentschrift 833 487 beschriebenen Beheizung, welche lediglich zur Erzeugung des laminaren Gegenstroms oder zur Verstärkung desselben dienen soll, wobei verhältnismäßig geringe Temperaturdifferenzen ausreichend sind, liegt darin, daß bei der Thermodiffusion sehr viel höhere Temperaturdifferenzen erforderlich sind. Bei einem Gas, welches innerhalb eines geschlossenen Raumes sehr erheblichen Temperaturunterschieden, d. h. solchen von mehreren hundert Grad, ausgesetzt ist, tritt eine Wanderung der leichten Moleküle in das Gebiet der hohen Temperaturen und eine Wanderung der schweren Moleküle in das Gebiet der niederen Temperaturen ein.

Entsprechend dem Vorhergesagten soll also eine Zentrifuge, welche nach den Angaben der Patentschrift 833 487 ausgebildet ist, eine zusätzliche Heizung bzw. Kühlung erfahren, so daß Temperaturdifferenzen von mehreren hundert Grad, z. B. von etwa 300°, erzeugt werden. Da in der Zentrifuge die schweren Moleküle entsprechend der Zentrifugalkraft nach außen, die leichten Moleküle dagegen in Richtung der Achse wandern und infolge des laminaren Gegenstroms sich die leichten Moleküle schließlich am oberen Ende der Zentrifuge und die schweren am unteren Ende der Zentrifuge ansammeln, wo sie entnommen werden sollen, so muß bei der erfindungsgemäßen Anwendung der Thermodiffusion auf die Zentrifuge das Temperaturgefälle derart zur Anwendung kommen, daß die Zerlegungskräfte unter dem Einfluß der Fliehkraft und unter dem Einfluß der Thermodiffusion gleichgerichtet sind. Hieraus ergibt sich, daß die Zentrifuge von der Mitte her, d. h. von der Achse aus oder in der Nähe der Achse geheizt werden muß. Eine zusätzliche Kühlung des Außenmantels wird in vielen Fällen zweckmäßig sein, jedoch kann die Kühlung durch die Außenluft unter Umständen schon ausreichend sein. Man kann auch daran denken, um den Außenmantel herum einen Kühlmantel anzubringen, der nicht einmal mit zu rotieren braucht, sondern fest angeordnet sein kann, wenn er dicht genug zum Außenmantel angeordnet ist.

Die Heizung kann z. B. dadurch erzeugt werden, daß die rotierende Achse hohl ausgebildet und von einem heißen Gas durchströmt wird. Man kann auch in der hohlen Achse einen elektrischen Heizkörper unterbringen oder einen solchen Heizkörper auf der Achse anbringen. Eine weitere Möglichkeit besteht z. B. darin, daß man eine Heizspirale auf die rotierende Achse aufwickelt, welche von einem flüssigen oder gasförmigen Heizstoff durchströmt wird.

Die bisherigen rechnerischen Untersuchungen haben ergeben, daß die Geschwindigkeitssteigerung des laminaren Gegenstroms unter dem Einfluß des bei zusätzlicher Thermodiffusion auftretenden Temperaturgefälles in der Regel nicht so stark ist, daß die zulässige Gasgeschwindigkeit überschritten wird. Sollte dies in Ausnahmefällen doch eintreten, so kann eine Hemmung im Sinne der Patentschrift 833 487, z. B. durch gelochte Bleche, Drahtnetze od. dgl. erfolgen.

In der Patentschrift 833 487 ist bereits gesagt worden, daß im Zentrifugenraum unter Umständen Längsrippen radial angeordnet werden sollen, welche die Richtung und Geschwindigkeit des laminaren Gegenstroms günstig beeinflussen sowie auch die Rotation der Zentrifuge auf den Gasinhalt übertragen sollen.

Im Zusammenhang mit der Erfindung kann diesen Längsrippen die weitere Aufgabe zukommen, von der Achse her auf das Gas die Wärmeübertragung und entsprechend in der Nähe des Außenmantels die Wärmeabfuhr vom Gas auf den Außenmantel zu verbessern. Unzweckmäßig aber wäre es, wenn durchgehende Rippen eine direkte Wärmeleitung zwischen Achse und Außenmantel herstellen würden. Zur Durchführung der Erfindung wird es daher, wenn durchgehende Rippen aus Festigkeitsgründen erforderlich sind, zweckmäßig sein, sie ganz oder teilweise aus solchen Stoffen herzustellen, welche genügend schlechte Wärmeleiter sind.

Die Erfindung ermöglicht eine Steigerung der Leistungsfähigkeit von Gaszentrifugen nach der Patentschrift 833 487 sowohl hinsichtlich des zulässigen Durchsatzes wie hinsichtlich der erzielbaren Trennwirkung, wenn man gleich große Zentrifugen vergleicht. Der Vorteil kann aber auch darin bestehen, daß man eine bestimmte Zerlegungswirkung mit einer kleineren Zentrifuge erreichen kann, als wenn nur die Zentrifugalkraft allein wirksam wäre.

Es wird in manchen Fällen vorteilhaft sein, statt einer verhältnismäßig großen Zentrifuge, mehrere kleinere Zentrifugen zu benutzen, welche derart hintereinandergeschaltet sind, daß das angereicherte Gas in der nächstfolgenden Zentrifuge weiter angereichert wird und das Restgas einer vorhergehenden Zentrifuge nochmals zugeführt wird.

PATENTANSPRÜCHE:

1. Verfahren zur Zerlegung von Gasgemischen in Zentrifugen, in denen ein Kreisstrom als achsparalleler laminarer Gegenstrom geführt wird, wobei Zentrifugen angewendet werden, deren axiale Länge wesentlich größer ist als ihr äußerer Durchmesser und bei denen die Ableitung der Zerlegungsprodukte aus dem Läufer der Zentrifuge an Stellen erfolgt, welche in der Projektion auf die Welle gemessen, weit voneinander entfernt sind, dadurch gekennzeichnet, daß die Zerlegungskräfte durch ein von der Zentrifugenachse zum Zentrifugenumfang gerichtetes, eine zusätzliche Thermodiffusion bedingendes, etwa mehrere hundert Grad betragendes Temperaturgefälle gesteigert werden.

2. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1, dadurch gekennzeichnet, daß die Zentrifuge bei oder in der Nähe der Achse beheizt wird.

3. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1, dadurch gekennzeichnet, daß der Außenmantel der Zentrifuge gekühlt wird.

4. Vorrichtung zur Durchführung des Verfahrens nach Anspruch 1, dadurch gekennzeichnet, daß die Zentrifuge am Außenmantel oder an Achse und Außenmantel Längsrippen hat, die radial in den Zentrifugenraum gerichtet sind.

5. Vorrichtung nach Anspruch 4 mit Längsrippen an der Achse und am Außenmantel, welche miteinander verbunden sind, dadurch gekennzeichnet, daß die Rippen entweder durch schlechte Wärmeleiter miteinander verbunden sind oder ganz aus solchem Material bestehen.

Figure D.141: Another Linde Eismaschinen patent on gas centrifuges, filed by Helmuth Hausen and Klaus Clusius in 1940 [German Patent DE 872,936]. Note the use of countercurrent flow inside the centrifuge to improve the separation efficiency.

[There was a large program spread out among several collaborating groups in the Hamburg-Kiel area to design, build, and operate a series of increasingly sophisticated gas centrifuges for uranium enrichment. That work was conducted by physicists and engineers such as Konrad Beyerle (at Anschütz, a gyroscope company in Kiel that already had decades of experience making high-precision rapidly rotating machinery), K. H. Eldau, Wilhelm Groth, Paul Harteck, Johannes Hans Jensen (who later won a Nobel Prize for the nuclear shell model), Werner Kuhn, Detlof Lyons (who also worked for the Reichspost), Hans Martin, Hans Suess, Albert Suhr, and others.

The U.S. Alsos Mission captured several reports written by this Hamburg-Kiel centrifuge program. Note that these reports do not cover the work of other German centrifuge programs and do not even cover all the work of the Hamburg-Kiel program. The extant reports tend to be from the earlier days of the Hamburg-Kiel program, and to focus on fundamental centrifuge design issues, not mass production or operational use of centrifuges. Unless otherwise indicated, text for G-series captured German nuclear reports cited here consists of the English-language abstracts prepared by U.S. scientists who studied the German reports.]

G-82. Wilhelm Groth. Status of Work on Building an Ultracentrifuge. 1941.

Rotor is 40 cm long and 14.5 cm diameter and operates at 50,000 rpm. On the basis of calculations, with a separation factor of 7.4%, the centrifuge would deliver more than 2 kg of hexafluoride which would be enriched more than 7%. Construction of ultracentrifuge still (Dec. 14, 1941) in progress.

G-83. Wilhelm Groth and Hans Suess. Status of Work on Isotope Separation of Preparation 38 (U_3O_8) at the Institute of Physical Chemistry, University of Hamburg. Separation Column Experiment and Construction of Ultracentrifuge. Analysis of Tests. 1941.

Preparation of UF_6. Corrosion tests showed nickel as only practical construction material, but in separation column the continuous removal of hexafluoride layer from the metal prevented operation of unit at 360^oC (temperature of boiling Hg). 3.7 m separation column was built of nickel. Inner (hot) tube outer diameter was 18 mm, 2 mm wall thickness; outer (cold) tube was 28 mm outside diameter. Separation between two tubes was therefore 3 mm. Separators were provided to reduce convection disturbances. Later a 5.7 m column was built. Tests with xenon and with methane to enrich isotope C^{13} were successful but no success in enriching U^{235} (separation effect less than 1%).

Ultracentrifuge is being built. Rotor to be 400 mm long and 115 mm diameter and to run in a vacuum chamber 625 mm long and 150 mm diameter, air or electric motor drive to be used. Speed up to 120,000 rpm. Lubricant developed consisted of a paste made from apiezon grease and sodium fluoride.

Methods used to check U isotopes separation are outlined.

G-95. Johannes Hans Jensen. The Ultracentrifuge Method for Separating Uranium Isotopes. 1941.

Since the thermal diffusion constants of UF_6 are so very small it was decided to investigate the ultracentrifuge methods of separating the isotopes. On the basis of a theoretical analysis, a 2 meter high centrifuge can enrich to double the value 1.5×10^{-2} grams of hexafluoride per day. This centrifuge is to operate with a laminar countercurrent—"a circulation centrifuge."

Suggest centrifuge divided vertically into chambers to prevent back diffusion. A 12 chamber centrifuge would increase the yield 1.44 times the circulation centrifuge but would require a mechanism so complicated as to be impractical.

Theoretical calculations are given for a centrifuge where the centrifugal forces are so great that the pressure differential between inner and outer wall is very large.

G-107. Hans Martin and K. H. Eldau. Appendix to Report of 15 July 1941 on the Construction of an Ultracentrifuge to Separate Isotopes. The Stability of Some Metals to UF_6 Vapor at Room Temperature and at 50^oC. 1941.

Corrosion tests of UF_6 on various metals and alloys. Description of special apparatus to avoid contamination. Tests run at 20 and 50^oC and at 16 and 55 mm Hg of UF_6 with exposure time varying from 20 to 80 hours. Weight increase of some sample metals in mg/cm^2. Copper = 0.036; lead = 0.25; dural = 0.03; V2A steel = 0.05. Results for other metals tabulated.

G-145. Wilhelm Groth. Report on Conference with Professor Svedberg and Dr. Pedersen of the Institute of Physical Chemistry at the University of Upsala (Sweden). 1942.

Notes on discussions regarding ultracentrifuges, a series of which were planned for Germany.

1. Description of foundations used at Upsala to avoid transmission of shock and reduce bearing loads.

2. Oil and water piping arrangement. Prefer individual piping to each centrifuge in order not to disturb whole series of centrifuges whenever one unit has to be shut down. Position of pumps etc. Use of hydrogen to keep out air and keep uniform temperature.

3. Use of packings. Bearing tolerances (held to .015 mm).

4. Balancing machines developed in Sweden which easily measure rotor unbalance of 0.5 mg cm.

G-146. Wilhelm Groth. Separation of Uranium Isotopes by the Ultracentrifuge. I. Enrichment of the Xenon Isotope in a Single Stage Ultracentrifuge. 1942.

Detailed description of Beams type centrifuge with a rotor 200 mm long and 128 mm outer diameter (58 mm inner diameter) operating in a 10^{-3} mm Hg vacuum. Description how impurities were removed from Xe before centrifuging. Centrifuge operated at 50,000 rpm and with Xe at an average atomic weight of 131.13 the pressure relationship between axis and periphery of rotor was 10.4:1. Separation of Xe isotopes successful. Data presented in tables of sample separations compare favorably with theoretical values. Enrichment obtained was 0.056–0.093. Photographs of centrifuge are included.

G-147. Wilhelm Groth. Separation of the Uranium Isotopes by the Separation Tube and the Ultracentrifuge. 1942.

Attempts to separate U isotopes in separating columns 3.70 meters and 5.70 meters were unsuccessful. Isotope enrichment was less than 1% whereas 8 and 14% enrichments were expected. Columns were built of Ni with the inner tube heated to between 100 and 360^oC and the outer tube kept between 12 and 65^oC. This small separation effect was ascribed to a very small thermodiffusion coefficient. Since experiments seem to prove U isotope separation was not possible with separation column, it was decided to try the ultracentrifuge. Ultracentrifuge on Beams principle was built with a rotor 115 mm inner diameter and 400 mm long. Electric drive used with speeds up to 100,000 rpm. Lubricant was paste of apiezo grease and sodium fluoride. Theoretical separation factors of the ultracentrifuge were determined. With ideal conditions should be able to deliver 2 kg UF_6 with the U^{235} enriched 7%.

G-148. Wilhelm Groth and Hans Suess. Status of Work on Separation of Isotopes of Preparation 38. 1942.

General summary of work done to date (Oct. 1942). Method of preparing UF_6. Corrosion tests with UF_6. Use of Ni with temperature limits at 360^oC in separating columns. (See G-32 and G-83.) Experiments with 3.70 m separating column (18 mm diameter of inner tube, 28 mm diameter outer tube), 3 mm separation with separators to overcome convection (See G-83). Experiments with 5.70 mm separating columns. Separation of U isotopes very small, although tests with Xe and methane (to enrich C^{13}) were successful. This explained by small thermodiffusion coefficient of U. Proposed solution is higher temperature operation of column, but corrosiveness of UF_6 prevents this. Use of ultracentrifuge (See G-147). Proof of separation of U isotopes by measurement of alpha activity with correction for U^{234}.

G-149. Wilhelm Groth and Albert Suhr. Separation of Uranium Isotopes by the Ultracentrifuge. II. Enrichment of Uranium Isotopes U_{234} and U_{235} in a Single Stage Ultracentrifuge. 1942.

Same centrifuge as used in G-146 for Xe now used with UF_6. Use of apiezo grease and sodium fluoride as seal lubricant. In a series of runs, average enrichment of $U^{234} = 3.6\%$ and $U^{235} = 2.7\%$. In another series of runs the following enrichments were achieved $U^{234} = 3.2\%$, $U^{235} = 2.4\%$, and $U^{234} = 5.2\%$, $U^{235} = 3.9\%$. These values are less than theoretically expected and are probably due to contamination which occurs when the samples are drawn off.

G-158. Paul Harteck and Johannes Hans Jensen. Calculation of the Separation Effect and the Yield of Various Arrangements of Centrifuges in Order to Improve the Efficiency of a Single Centrifuge. 1942.

New design gas centrifuge planned which will be a single unit whose rotor will be divided into chambers. The gas flow will go from the axis of one chamber to the periphery of the next chamber. Furthermore there will be a periodic change of direction in the gas stream flowing through the chambers. Calculations are presented for (1) the separation effect of a simple single chamber centrifuge, (2) the separation effect achieved with a multi-chamber centrifuge with undirectional gas flow, (3) the separation effect achieved with a multi-chamber centrifuge with oscillating gas flow, (4) calculations evaluating the pressure differences and thermal effects. Short note on possibilities of a double centrifuge.

G-175. Hans Martin. Spontaneous Gas Convection on Conducting Walls in a High Centrifugal Field. 1942.

Small local temperature changes often disturb the separation in an ultracentrifuge; therefore a mathematical analysis is made of the thermal convection processes within the centrifuge. Gas movements in a high centrifugal field occur close to the wall (hot or cold) but not in the gas filled chamber where the strata are quite stable. Calculations for flow due to temperature differential (flow opposite to the gravitational force). Convection speed. Optimum wall separation in the centrifuge. Convection currents in the ultracentrifuge which are caused by temperature variations are proportionally reduced with higher centrifugal fields, lower gas pressures, and with a reduction in the gas volume which comes in contact with heat conducting walls. Relationship between temperature differentials and velocity of flow.

G-215. Wilhelm Groth, Paul Harteck, and Albert Suhr. Separation of Uranium Isotopes by the Ultracentrifuge. III. Enrichment of Xenon and Uranium Isotopes by the Cascade Method. 1943.

Figs. missing. No illustrations of the equipment described. Progress report on work done in 1943. New type bearing developed and new lubrication system. Use of upper and lower capillary tubes permitted continual operation. Rotor divided into 10 chambers with periphery of one chamber connected to the axis of its neighbor (cascade method). Provisions to prevent temperature differentials. Centrifuge operated on two endurance runs of 100 hours each. Enriched 25 g of hexafluoride 3 1/2 to 7% (U^{234}). Theoretical enrichment value = 14%.

G-234. Hans Martin. Chamber Centrifuge with Axial Temperature Gradient. 1943.

The design of a multi-chambered ultracentrifuge for the enrichment of uranium isotopes in UF_6 is detailed. The unit has a counter-current gas flow based on the thermosiphon principle. The rotor itself is a cylinder about 1 meter long, 10 cm radius, rotating at 66,000 rpm. This rotor is divided into 20 chambers. One end of the unit is heated and the other end is cooled at the same rate. Fins are built into the end chambers to improve heat transmission to the rotor in order to ensure a proper temperature gradient through the individual chambers. This gradient is to be maintained in spite of the heat generated by gas friction. The maximum U^{235} enrichment per chamber is expected to be 5.5% and the daily capacity of the centrifuge 50 g UF_6.

G-276. Detlof Lyons. Theory of Isotope Separation by Ultracentrifuges with Thermal Convection. 1944.

Theoretical equations are derived for gaseous diffusion factors relative to separation of two isotopes and mass-transport through the centrifuge diameter. Thermoconvection is achieved by raising the temperature of an inner cylinder of fluid above that of the outer layer. Equations for computation of optimum values of temperature differences, speed of flow profile, and separation factor are given. A continuous centrifugation process for production purposes is described.

G-330. Konrad Beyerle, Wilhelm Groth, Paul Harteck, et al. Correspondence, Cost Estimates, and Technical Data Concerning the Construction of the Ultracentrifuge by the Anschütz Company. 1944–1945.

Correspondence between Harteck and staff members of the Anschütz Co., cost estimates and reports dated Jan. 1944 to Apr. 1945 are included.

[Includes information on apparently aborted plans to set up multiple centrifuges in Kandern and Freiburg.]

G-331. Konrad Beyerle, Wilhelm Groth, Paul Harteck, et al. Technical Letters Concerning the Ultracentrifuge, Taken from Dr. Groth's File. 1941–1944.

Correspondence between Dr. Groth and K. Beyerle of the Anschütz Co. dated, from 1941 to 1944, makes up most of the file.

G-332. Folder Containing Blueprints for Construction of an Ultracentrifuge.

The 165 blueprints included in this folder are for construction of an ultracentrifuge using the UZ III method of Harteck. A design is included for installation of the gas centrifuge GZA 451 in a building partly underground.

G-333/G-248. Konrad Beyerle. The Gas Centrifuge Setup GZA 451 for the German Federal Research Board. 12 December 1944.

Construction of an improved double ultracentrifuge for isotope separation is considered. An outlet pipe is connected to either top or bottom of each of the two centrifuge cylinders, a pipe connects the opposite sides of the cylinders, and a pipe entering this connecting piece feeds the mixture to be separated into both cylinders. Advantage of this arrangement is that each cylinder is to be provided only with two instead of three pipe connections. Plates with central openings divide the cylinders into a number of chambers. Designs for construction of the centrifuge and all parts are illustrated and described in detail. Advantages and disadvantages of different plans of construction and details of operation are considered.

Report G-248, printed and in more finished form, blueprints of the design, and a report by the Alsos Mission are included in this folder.

G-334. Folder Containing Blueprints for Construction of an Ultracentrifuge.

Seventeen blueprints for construction and operation of an ultracentrifuge using the UZ III method of Harteck, and 5 drawings of pressure-radius curves for different temperatures and rotational speeds of the instrument are included in the folder.

G-335. Folder Containing Drawings, Blueprints and Photographs of the Ultracentrifuge.

Fifteen photographs of the ultracentrifuge setup in Freiburg i/Br., 7 pencil drawings and 8 blueprints for centrifuge construction are included in the folder.

G-336. Folder Containing Blueprints for Construction of an Ultracentrifuge.

Thirteen blueprints and two sketches for construction and operation of the UZ III ultracentrifuge setup are included in this folder.

py No. 2 of 5 copies.

21 April 1945

SUBJECT: Ultra-centrifuge installation in Celle. 17-20 April 1945.

1. At the TA laboratory at Stadtilm information was obtained that the ultra-centrifuge experiments had been recently evacuated to Celle, near Hannover, at a spinning mill. They had evacuated Freiburg in November.

2. The target was investigated by ALSOS as soon as it was available. The director, Harteck, was not present, he is still at the institute in Hamburg. His right hand man, Dr. W. Groth, was in charge at Celle, together with Dr. Suhr and Dr. Faltings. It was originally set up for eight scientists.

3. The equipment is definitely a small scale set up. If working smoothly it may be capable of producing 50 grams per day of enriched material. The enrichment is at best about 15 per cent, which means that the isotope ratio is 1/120 instead of the original 1/137.

4. The separation is done with gaseous UF_6. Groth discovered that it is possible to produce this gas directly from the oxide, without having to make the metal first. He has a patent on this. It is produced this way by I. G. Farben in Leverkusen in rather small quantities, perhaps about 30 pounds a month.

5. The oil used in the centrifuge contained powdered sodium fluoride in suspension so as to saturate it against the effect of UF_6.

6. Groth was very cooperative. He had been strongly anti-Nazi, though formally a party member since 1938, when he was appointed at Hamburg.

7. The correspondence and other papers captured at the place did not give any new information. Most interesting are perhaps the blueprints of the centrifuge.

8. As found at Stadtilm, the centrifuge is built by Anschütz and Co. in Kiel.

9. Some of the correspondence has some interest as confirmation of intelligence obtained before. It is of course gratifying to ALSOS investigators to find how various letters found here dovetail with the correspondence found at Strassburg.

10. The net result is the same as that obtained at other places, namely that the TA effort in Germany is on a very small scale, purely laboratory work, but within view possible large scale developments in the distant future.

Figure D.142: Alsos Mission. 21 April 1945. SUBJECT: Ultra-centrifuge installation in Celle. 17–20 April 1945 [NARA RG 77, Entry UD-22A, Box 166, Folder 32.24-1 GERMANY: Research–Res. Inst. & other Facilities (1943–Apr. 1945)]

[The work described in some of those captured German reports was then summarized in a U.S. report by the American physicist Jesse Beams, who had tried and failed to build useful uranium gas centrifuges in the United States during the war:]

G-344. Jesse W. Beams. Report on the Use of the Centrifuge Method for the Concentration of U^{235} by the Germans. 9 April 1946.

This brief report is based upon a number of captured German reports and letters sent to me by Colonel Peterson. While this list is apparently not complete, it allows one to get an idea of the progress the Germans were able to make.

Immediately after Bohr and other showed that the isotope 235 of Uranium was responsible for the observed Nuclear Fission, the Germans began an intensive search for a suitable method of concentrating it. Their first step was to produce the UF_6 gas in sufficient quantities for use in the Thermal Diffusion Method of Clusius and Dickel. This production was carried out by the I.G. Farben Company under the direction of Dr. Noack. Experiments performed from 1939 to 1941 with the Thermal Diffusion Method using the gas, UF_6, were uniformly unsuccessful although in the meantime the necessary properties of UF_6 such as viscosity and vapor pressure were well established.

In the Summer of 1941 Groth, Harteck, and Jensen in Hamburg and Martin and Kuhn in the University of Kiel focused their attention on the Centrifuge Method for concentrating Uranium 235. They first made a study of the theory and concluded that the method had promise. Accordingly in Sept. 1941 the Firm of Anschütz and Co. in Kiel started construction of a gas centrifuge under the direction of Dr. Beyerle, head of their Research Department. The rotor was 40 cm long with an O.D. of 14.5 cm and was driven electrically up to 60,000 r.p.m. Apparently this first centrifuge was patterned somewhat after some of our early (1936–38) published work on isotope separation by centrifuging. With this apparatus Groth obtained separation of the Xenon isotopes in May 1942 and a concentration increase of 3.9% of Uranium 235 in a small sample in August 1942. During 1943 a large number of technical improvements were made in the centrifuge apparatus, and the workers felt that it was trustworthy for long period operation.

At the suggestion of Harteck a continuous method of operation was adopted, called the “Rocking Method” and designated as UZ III. It was assembled and tested in Freiburg by the Firm of Hellige and Co. Two identical centrifuges were used, one for stripping and the other for concentrating the U 235. Each centrifuge rotor was divided into 10 chambers in such a way that the periphery of one chamber connected through a baffle system to the axis of the next chamber. The bottom ends of the two rotors were connected together and the gas was made to oscillate or flow back and forth in such a manner as to produce enriched U 235 at the top of one rotor and the stripped material at the top of the other rotor. The first experiments with this method gave 40% of the theoretical value and in May 1944 Groth in writing to Gerlach said: “The experiments of the last week have produced a separation of 70% of the theoretical value which is more than had been hoped for.” In the meantime Anschütz and Co. had developed a rotor 70 cm long and 15 cm O.D. which weighed 15 kg. Their rotors were made either of an aluminum alloy, “Bondur,” or of steel and had an inside peripheral speed of about 3.9×10^4 cm/sec.

As an alternate to Harteck's "Rocking Method" Martin and Kuhn at Kiel worked out the theory for a so-called "Thermal Siphon Method" which consisted of cooling the outer walls of the centrifuge and heating along the axis. This was supposed to produce circulation in the manner of the Clusius-Dickel experiment, and the enriched fraction would be drawn off at the top of the rotor. The method apparently was never tried although experiments were planned.

From the reports one gathers that as early as 1942 the Germans arrived at the conclusion that the centrifuge method, even though expensive, probably stood the best chance of success of all of the methods for separating U 235. They placed an ever growing emphasis on the problem but it never reached beyond the experimental stage.

It was abundantly clear that the air war was primarily responsible for a production plant not getting much further than the planning stage. The Anschütz Co. was badly bombed in Kiel and development was slowed down by the difficulty of getting materials from Essen, Vienna, etc. At the end of the war they were planning to put a factory underground near Kandern.

In comparing the progress with the Centrifuge Method of separation made by the Germans and by ourselves it is clear that at the end of the war they were far behind where we were in this country at the end of 1943 when support of the centrifuge project was effectively cut off. However, they made some headway both with the theory and experiment.

[Beams's final editorial comments appear to be countered by the facts that:

- German work on gas centrifuges for a variety of applications began sometime before 1895 (p. 3495), many decades before Beams's work.
- Beams's centrifuge experiments were considered but abandoned by the U.S. Manhattan Project because of their poor performance.
- An enormous amount of the German work on gas centrifuges was not mentioned in these captured G-reports and Beams's analysis of them (as illustrated by other documents in this section).
- The German-developed gas centrifuges became the basis of uranium enrichment worldwide after the war, since they were more efficient than any of the uranium enrichment methods (Beams-type centrifuges, calutrons, gaseous thermal diffusion, and liquid thermal diffusion) developed by the Manhattan Project.]

Hans Martin and Werner Kuhn. 1941. Multiplikationsverfahren zur Trennung von Gasgemischen, insbesondere bei Anwendung von Schwerefeldern. *Zeitschrift für Physikalische Chemie A* 189:219–316. See p. 3525.

Es wird ein Multiplikationsverfahren angegeben, mit dessen Hilfe es allgemein möglich ist, in Gasgemischen (Isotopengemischen) auftretende schwache Entmischungseffekte, wie sie beispielsweise bei Einwirkung eines Gravitationsfeldes oder eines Temperaturgefälles beobachtet werden (Einzeleffekte), grundsätzlich beliebig stark zu vervielfachen und damit eine im Einzeleffekt nur unvollkommene Zerlegung eines Gemisches in beliebigem Maße zu vervollständigen. Es ist ein wesentlicher Bestandteil des Verfahrens, daß das Gemisch innerhalb des Hohlraumes, in welchen es eingeschlossen ist, in bestimmter Weise zirkuliert.

Den überwiegenden Raum in der vorliegenden Mitteilung nimmt die Besprechung der Grundlagen eines Gastrennverfahrens (I. bis III. Kapitel) ein, bei welchem der Einzeleffekt (der vervielfacht werden soll) durch ein starkes künstliches Schwerefeld (I. Kapitel) hervorgerufen wird. Das Schwerefeld wird in einem rasch umlaufenden Zentrifugenkörper erzeugt. Es ergibt sich dabei als zufällige Besonderheit dieses Verfahrens, daß außer dem die Gastrennung verursachenden Einzeleffekt auch der für die Multiplikation dieses Effektes erforderliche Gasumlauf durch dasselbe Schwerefeld hervorgebracht werden kann (Thermokonvektion).

A multiplication method is given by means of which it is generally possible to multiply weak demixing effects occurring in gas mixtures (isotope mixtures), such as those observed, for example, under the influence of a gravitational field or a temperature gradient (single effects), to any desired extent and thus to complete a decomposition of a mixture which is only imperfect in the single effect to any desired extent. It is an essential part of the process that the mixture circulates in a certain way within the cavity in which it is enclosed.

Most of the present communication deals with the fundamentals of a gas separation process (Chapters I to III) in which the single effect (which is to be multiplied) is caused by a strong artificial gravitational field (Chapter I). The gravitational field is generated in a rapidly rotating centrifuge body. An incidental feature of this process is that, in addition to the single effect causing the gas separation, the gas circulation required for the multiplication of this effect can also be produced by the same gravitational field (thermoconvection).

Der Frage nach einer zweckmäßigen Erzeugung der Gaszirkulation kommt nur mittelbare Bedeutung zu. Von grundlegender Bedeutung sind demgegenüber die Vorgänge, die sich als Folge dieser Gaszirkulation ergeben. Ihre Verfolgung an Hand des mitgeteilten Zentrifugenverfahrens führt auf ein Multiplikationsprinzip, welches allgemeinerer Anwendung fähig ist. Die Wirkungsweise dieses Prinzipes wird daher (im II. und III. Kapitel) besonders eingehend behandelt. Daneben werden auch speziellere Fragestellungen diskutiert, sofern diese einen wesentlichen Beitrag zur Lösung des Problems einer wirksamen Gastrennung im Schwerefeld darstellen. Hierher gehört außer der schon erwähnten Frage nach der Hervorbringung der Gaszirkulation insbesondere die Diskussion des Einflusses spezieller (zylindersymmetrischer) Hohlraumformen, wie sie durch die Notwendigkeit der Unterbringung des Gasgemisches in einem rasch rotierenden Zentrifugenkörper nahegelegt werden.

Das Multiplikationsprinzip läßt sich auf zweierlei Weise realisieren, und zwar entweder dadurch, daß der Gesamthohlraum durch Zwischenwände, die geeignete Öffnungen für die Gaszirkulation tragen, in eine größere Anzahl von Einzelkammern unterteilt wird (II. Kapitel), oder dadurch, daß dem Hohlraum eine besonders langgestreckte Form erteilt wird (III. Kapitel). Für den Trennvorgang bei jeder dieser Methoden wird eine einfache, durch Übersichtlichkeit ausgezeichnete Theorie entwickelt, aus welcher sich eine Reihe von quantitativen Ergebnissen ableitet, die die Leistungsfähigkeit der Methode hinsichtlich Trenngüte und Mengenumsatz in Abhängigkeit von den Arbeitsbedingungen und Apparatdimensionierungen zu beurteilen gestatten. Die gemeinsamen und unterscheidenden Merkmale der beiden Methoden werden besprochen.

The question of the appropriate generation of gas circulation is only of indirect importance. In contrast, the processes that occur as a result of this gas circulation are of fundamental importance. Tracing them on the basis of the centrifuge process described leads to a multiplication principle which is capable of more general application. The mode of operation of this principle is therefore dealt with in particular detail (in Chapters II and III). In addition, more specific questions are also discussed, provided that they make a significant contribution to solving the problem of effective gas separation in the gravitational field. In addition to the aforementioned question of how gas circulation is brought about, this includes in particular the discussion of the influence of special (cylindrically symmetrical) cavity shapes, as suggested by the need to accommodate the gas mixture in a rapidly rotating centrifuge body.

The multiplication principle can be realized in two ways, either by subdividing the total cavity into a larger number of individual chambers by means of partitions with suitable openings for gas circulation (Chapter II), or by giving the cavity a particularly elongated shape (Chapter III). For the separation process in each of these methods, a simple theory is developed which is characterized by clarity and from which a series of quantitative results are derived which allow the efficiency of the method to be assessed in terms of separation quality and volume conversion as a function of the working conditions and apparatus dimensions. The common and distinguishing features of the two methods are discussed.

Zum Schlusse (IV. Kapitel) werden die gewonnenen Ergebnisse, soweit sie nicht ausdrücklich den besonderen Verhältnissen auf Zentrifugenkörpern Rechnung tragen, auf das CLUSIUSsche Gastrennverfahren, bei welchem der Einzeleffekt durch Thermodiffusion anstatt Gravitationsdiffusion hervorgerufen wird, übertragen. Im Anschluß an eine vergleichende Diskussion, als deren Ergebnis unter anderem namentlich der im Vergleich zum Zentrifugenverfahren äußerst geringe (theoretische) Nutzeffekt des thermischen Verfahrens zu nennen ist, wird an Hand einer Reihe von in Frage kommenden Maßnahmen eingehend untersucht, ob sich der Nutzeffekt des Thermodiffusionsverfahrens unter Umständen erhöhen läßt. Eine solche Möglichkeit besteht grundsätzlich nicht.

Die verschiedenen zum Zwecke der Trennung von Gasgemischen möglichen Kombinationen eines Schwerefeldes mit einem Temperaturgefälle werden diskutiert.

Finally (Chapter IV), the results obtained are transferred to the CLUSIUS gas separation process, in which the individual effect is caused by thermal diffusion instead of gravitational diffusion, insofar as they do not expressly take into account the special conditions on centrifuge bodies. Following a comparative discussion, one of the results of which is the extremely low (theoretical) efficiency of the thermal process compared to the centrifuge process, a series of possible measures are used to examine in detail whether the efficiency of the thermal diffusion process can be increased under certain circumstances. In principle, there is no such possibility.

The various possible combinations of a gravity field with a temperature gradient for the purpose of separating gas mixtures are discussed.

Werner Kuhn and Hans Martin. 1941. Temperaturabhängigkeit der Adsorbierbarkeit als Mittel zur laufenden Fraktionierung oder Konzentrierung von Lösungen. *Zeitschrift für Physikalische Chemie A* 189:317–326. See p. 3526.

In Verallgemeinerung eines bisher in Spezialfällen angewandten Prinzips wird gezeigt: wenn sich in einem homogenen oder heterogenen System unter bestimmten, stationär aufrecht erhaltbaren Bedingungen (Kraftfelder, Temperaturgradienten usw.) ein Zustand herausbildet, bei welchem an den im Abstand $a/2$ (Abb. 1) befindlichen Punkten P_1 und P_2 ein Unterschied $(1 + \delta)$ in er relativen Konzentration eines in dem System vorhandenen Bestandteiles auftritt, so läßt sich der zunächst vorhandene Unterschied durch eine in dem System hervorgerufene und aufrecht gehaltene Bewegung in grundsätzlich beliebigem Maße steigern. Die anzuwendenden Geschwindigkeiten lassen sich in Abhängigkeit von den gewählten Dimensionierungen des Systems sowie in Abhängigkeit von dem im System maßgebenden Diffusionskoeffizienten angeben.

Als Beispiel wird besprochen die Racemattrennung, durchgeführt auf Grund davon, daß der Temperaturkoeffizient der Adsorbierbarkeit der d-Form eines aktiven gelösten Stoffes sich von Temperaturkoeffizienten der l-Form unterscheidet, falls als Adsorptionsmittel ein optisch aktiver fester Stoff gewählt wird.

Es werden ein Apparat und Versuche beschrieben, bei welchen eine teilweise Spaltung racemischer Mandelsäure unter Verwendung von Wolle als Adsorptionsmittel durchgeführt wird.

Generalizing a principle previously applied in special cases, the following is shown: if a state develops in a homogeneous or heterogeneous system under certain conditions (force fields, temperature gradients, etc.) that can be maintained in a stationary state, in which a difference $(1 + \delta)$ in the relative concentration of a component present in the system occurs at the points P_1 and P_2 located at $a/2$ (Fig. 1), the initially existing difference can be increased to any extent by a movement caused and maintained in the system. The velocities to be applied can be specified as a function of the selected dimensions of the system and as a function of the decisive diffusion coefficient in the system.

As an example, racemate separation is discussed, carried out on the basis that the temperature coefficient of adsorbability of the d-form of an active solute differs from temperature coefficients of the l-form if an optically active solid is chosen as adsorbent.

An apparatus and experiments are described in which partial cleavage of racemic mandelic acid is carried out using wool as the adsorbent.

Vorrichtung und Verfahren zur Trennung von Gasgemischen durch Anwendung von künstlich erzeugten Schwerefeldern

Patentiert im Gebiet der Bundesrepublik Deutschland vom 12. Juli 1938 an
Der Zeitraum vom 8. Mai 1945 bis einschließlich 7. Mai 1950 wird auf die Patentdauer nicht angerechnet
(Ges. v. 15. 7. 51)
Patentanmeldung bekanntgemacht am 12. März 1953
Patenterteilung bekanntgemacht am 28. Januar 1954

Es ist bekannt, daß man eine teilweise Trennung von Gas- oder Dampfgemischen, welche sich aus verschieden schweren Bestandteilen zusammensetzen, dadurch erreichen kann, daß man das Gasgemisch in einen Hohlkörper bringt und denselben mit hoher Umlaufzahl um eine Achse rotieren läßt. Durch das bei der hohen Umlaufzahl auftretende Schwerefeld wird eine Anreicherung der schwereren Bestandteile in den peripheren Teilen, eine verhältnismäßige Anreicherung der leichteren Bestandteile in den der Achse benachbarten Teilen des Hohlkörpers hervorgebracht. Es ist indessen bekannt, daß eine solche Trennung nur in recht geringem Ausmaße erfolgt und daß sie nur dann merkliche Beträge annimmt, wenn das Molekulargewicht der in dem Gemische vorliegenden Bestandteile große Unterschiede aufweist.

Um auch bei kleinen Unterschieden im Molekulargewicht, wie sie z. B. bei Luft oder bei Isotopengemischen vorliegen, eine weitgehende Trennung herbeizuführen, ist es notwendig, die bei der Zentrifugierung anfallenden Gasfraktionen wiederholt zu zentrifugieren. Es ist dabei naheliegend, anstatt einer einzigen eine Reihe von Zentrifugen vorzusehen und diese durch Rohrleitungen derart zu verbinden, daß die zweite Zentrifuge mit der in der ersten anfallenden schweren Fraktion gespeist wird, die dritte Zentrifuge mit der in der zweiten anfallenden noch schwereren Fraktion usf. Auf diese Weise können Fraktionen erhalten werden, in welchen der schwere Bestandteil stark angereichert ist. In entsprechender Weise kann selbstverständlich auch der leichte Bestandteil stark angereichert werden, wenn anstatt der schweren immer die leichte Fraktion in die nächstfolgende Zentrifuge übergeleitet wird.

Indessen ist die Ausbeute, die auf solche Weise erzielt wird, recht gering, wie das folgende einfache Zahlenbeispiel zeigt. Es handelt sich darum, den Sauerstoffgehalt der Luft von 20 auf 25 % zu erhöhen. Da bei einmaliger Zentrifugierung (wegen der begrenzten Festigkeit des Materials, aus welchem der rotierende Hohlkörper gefertigt ist) nur Fraktionen erhalten werden können, die im Prozentgehalt um rund zwei Einheiten auseinanderliegen, muß fünfmal hintereinander zentrifugiert werden. Zu diesem Zwecke seien also fünf Zentrifugen vorgesehen. In der ersten Zentrifuge wird die zugeführte Luft hälftig in zwei Fraktionen mit 19 und 21 % Sauerstoff zerlegt. Die 21 %ige Luft wird in die zweite Zentrifuge geleitet, wo wiederum eine hälftige Zerlegung in Fraktionen mit 20 und 22 % Sauerstoff stattfindet usw. Die fünfte Zentrifuge liefert schließlich Luft mit 23 und 25 % Sauerstoff. Bei jeder Zentrifugierung geht die Hälfte der jeweils zugeführten Luftmenge verloren. Wenn die in der ersten Zentrifuge verarbeitbare Luftmenge beispielsweise gleich 1 l/min ist, so kann dieser Zentrifuge (an 21 %iger Luft) nur $^1/_2$ l/min, der zweiten Zentrifuge nur $^1/_4$ l/min (an 22 %iger Luft), der fünften Zentrifuge schließlich nur noch $^1/_{32}$ l/min (an 25 %iger Luft) entnommen werden. Der weitaus größte Teil der anfänglich zugeführten Luft wird also in mehr oder weniger wertlose Zwischenfraktionen verwandelt, die entweder verworfen oder in einem umständlichen Verfahren gesondert aufgearbeitet werden müssen.

Im vorliegenden wird nun ein Verfahren mitgeteilt, bei welchem durch eine besondere Art der Führung der Fraktionen bei gleichem Aufwand an rotierenden Hohlkörpern eine erhöhte Ausbeute an hochangereicherten Fraktionen erzielt wird. Das Prinzip wird nachfolgend durch ein Beispiel an Hand von Fig. 1 erläutert. In diesem Beispiel sind wie in dem soeben besprochenen Zahlenbeispiel wiederum fünf Hohlkörper vorgesehen, die mit I bis V bezeichnet sind. Einem jeden dieser Hohlkörper entspricht eine Zentrifuge in dem vorigen Zahlenbeispiel. Daß die Hohlkörper in dem jetzt betrachteten Beispiel zu einer Einheit zusammengefaßt, d. h. anstatt auf getrennten Achsen auf ein und derselben Drehachse o gelagert sind, ist, wie im voraus bemerkt sei, belanglos. Wesentlich ist die Art der Führung der Gasfraktionen, die nun im folgenden beschrieben werden soll.

Wie Fig. 1 erkennen läßt, ist jeder Hohlkörper mit dem jeweils benachbarten bzw. mit den beiden benachbarten Hohlkörpern durch zwei Leitungen verbunden. So sind die Hohlkörper I und II durch die Leitungen s_I einerseits, i_I-k_I-w_{II}-h_{II} andererseits verbunden; die Hohlkörper II und III sind durch die beiden Leitungen s_{II} und i_{II}-k_{II}-w_{III}-h_{III} verbunden usw. Die Leitungen s_I, s_{II}, s_{III} … dienen der Ableitung der in den einzelnen Hohlkörpern am Außenrand anfallenden schweren Gasfraktionen; die Ausgangspunkte dieser Leitungen sind demgemäß in der aus der Figur ersichtlichen Weise möglichst weit von der Drehachse entfernt, d. h. auf möglichst großem Radius angeordnet. Die Leitungen i_I-k_I-w_{II}-h_{II}, i_{II}-k_{II}-w_{III}-h_{III} … andererseits dienen in entsprechender Weise der Ableitung der in den der Drehachse benachbarten Bezirken der einzelnen Hohlkörper anfallenden leichten Fraktionen; die Ausgangspunkte h_{II}, h_{III}, h_{IV} … dieser Leitungen sind demgemäß auf einem möglichst kleinen Radius angeordnet.

Für die Erläuterung der Wirkungsweise der Vorrichtung ist es belanglos, daß die inneren Rohrverbindungen i_I-k_I-w_{II}-h_{II} usw., wie aus Fig. 1 ersichtlich ist, gegenüber den äußeren s_I, s_{II} usw. besonders lang und schleifenförmig gebogen sind. Diese Rohrschleifen stellen nämlich, wie an späterer Stelle erläutert wird, lediglich eine besondere Art einer Fördervorrichtung dar. Die Fördervorrichtung bewirkt, daß das in den Hohlkörpern I bis V befindliche Gasgemisch in der durch Pfeile angedeuteten Weise in Zirkulation gehalten wird.

Die Zirkulation selbst ist wie folgt gekennzeichnet: Das Gemisch strömt aus dem Randbezirk des Hohlkörpers I durch Leitung s_I in den Hohlkörper II über, aus dem Randbezirk des Hohlkörpers durch s_{II} in den Hohlkörper III usw., bis es in den Hohlkörper V gelangt, in welchem es in Richtung auf die Drehachse strömt. Es gelangt dann durch die Leitung h_V-w_V-k_{IV}-i_{IV} wieder in den Hohlkörper IV zurück; aus dem der Drehachse benachbarten Bezirk dieses Hohlkörpers strömt es weiter durch die Leitung h_{IV}-w_{IV}-k_{III}-i_{III} nach Hohlkörper III usw., bis es schließlich durch die Leitung i_I wieder in den Hohlkörper I zurückgelangt, in welchem es nach außen strömt und dann den Kreislauf durch das ganze Hohlkörpersystem von neuem beginnt.

Der soeben beschriebene Kreislauf des Gasgemisches hat zur Folge, daß in den endständigen Hohlkörpern I und V alsbald Gasfraktionen auftreten, die in der prozentischen Zusammensetzung stark verschieden sind. Welche Trennungsgrade auf solche Weise erreichbar sind, soll nunmehr durch ein Zahlenbeispiel gezeigt werden.

Es sei wiederum der Fall betrachtet, daß Luft mit 20 % Sauerstoffgehalt zentrifugiert werden soll. Die Umlaufzahl der Zentrifuge sowie die geometrischen Abmessungen der einzelnen Hohlkörper I, II … seien dieselben wie bei dem eingangs betrachteten Zahlenbeispiel, und zwar Umlaufzahl 35 000 Umdr./min, Höhe des Hohlraums 7 cm, größter Radius 10 cm, kleinster Radius 3 cm, Rauminhalt des Hohlkörpers also etwa 2 l. Entsprechend dem früher angewandten Durchsatz von 1 l/min durch den ersten Hohlkörper wird jetzt mit einer Zirkulationsgeschwindigkeit von 1 l/min gearbeitet (bei höherer Strömungsgeschwindigkeit würde die Trennwirkung des einzelnen Hohlkörpers durch die Strömung gestört, d. h. herabgesetzt werden).

Der Trennprozeß beginnt damit, daß in allen Hohlkörpern in den äußeren Bezirken Fraktionen mit 21 %, in den zentralen Bezirken Fraktionen mit 19 % Sauerstoff auftreten. Durch den Kreislauf werden die sauerstoffreichen Fraktionen fortlaufend nach Hohlkörper V, die sauerstoffarmen nach Hohlkörper I geschafft. Dies führt allmählich zu einer Anreicherung des Sauerstoffs in V und einer entsprechenden Verarmung an Sauerstoff in I. Es zeigt sich, daß sich dieser Prozeß so lange fortsetzt, bis im Innenbezirk des Hohlkörpers I Luft mit 15 %, im Außenbezirk des Hohlkörpers V Luft mit 25 % Sauerstoff vorhanden ist. An den übrigen Stellen des Hohlkörpersystems treten Zwischenfraktionen auf, deren Sauerstoffgehalt zwischen 15 und 25 % schwankt.

Dieser Endzustand, der auch bei beliebig langer Fortsetzung des Kreislaufs unverändert bleibt, ist in Fig. 1 für den allgemeinen Fall, daß pro Hohlkörper eine Verschiebung des Prozentgehalts an schwerem Bestandteil um $\pm\,\delta$ Einheiten erzielt wird, durch Eintragung der Zahlen -5δ, -3δ, $-\delta$, $+\delta$ usw. gekennzeichnet. In dem betrachteten Beispiel ist also $\delta = 1$, und man liest dann aus Fig. 1 ab, daß beispielsweise in IV an der Außen- und Innenbegrenzung dieses Hohlkörpers im Endzustand Zwischenfraktionen mit $20 + 3 = 23$ % bzw. $20 + 1 = 21$ % Sauerstoffgehalt auftreten. Die in den endständigen Hohlkörpern I und V auftretenden schwersten und leichtesten Fraktionen (mit $20 + 5 = 25$ und $20 - 5 = 15$ % Sauerstoffgehalt) liegen, wie man ebenfalls sofort an der Figur abliest, im Prozentgehalt fünfmal weiter auseinander als die Fraktionen, die man durch Anwendung eines einzigen Hohlkörpers herstellen kann. Der durch einmalige Zentrifugierung erzielbare Trennungsgrad wird also in der beschriebenen Vorrichtung um einen Faktor, der gleich der Anzahl der Hohlräume ist, vervielfacht.

Falls die schwerste und leichteste Gasfraktion laufend während des Betriebes entnommen werden soll, muß an den endständigen Hohlkörpern je eine Ableitung angebracht werden, die es gestattet, die betreffende Fraktion nach einem ruhenden Behälter abzuleiten. In diesem Falle ist es dann zweckmäßig, an einem der Hohlkörper außerdem eine Zuleitung vorzusehen, damit die in dem Hohlkörpersystem befindliche Gasmenge laufend durch frisches, ungetrenntes Gasgemisch von außen ergänzt werden kann. Bei dieser voll kontinuierlichen Arbeitsweise überlagert sich der bereits beschriebenen Kreislaufströmung eine weitere Strömung, deren relativer Anteil mit dem Gasdurchsatz, d. h. mit der Gasmenge, die dem System laufend in der Minute ungetrennt zugeführt und getrennt wieder entnommen wird, anwächst. Der Durchsatz darf (ähnlich wie die Zirkulationsgeschwindigkeit) nicht beliebig gesteigert werden, da sonst die erzielbaren Entmischungsgrade hinter den oben angegebenen zurückbleiben.

Es zeigt sich, daß bei dem betrachteten Beispiel (Zirkulationsgeschwindigkeit 1 l/min) der Durchsatz auf etwa $^1/_5$ l/min gesteigert werden darf. Wenn also (etwa dem mittleren Hohlkörper III) pro Minute $^1/_5$ l 20 %ige Luft zugeführt wird, so kann aus den Hohlkörpern I und V je $^1/_{10}$ l Luft von 15 bzw. 25 % Sauerstoffgehalt pro Minute entnommen werden, d. h. die Vorrichtung gestattet es, in 1 Minute $^1/_5$ l 20 %ige Luft in $^1/_{10}$ l 25 %ige und $^1/_{10}$ l 15 %ige Luft zu verwandeln.

Vergleicht man dieses Ergebnis mit dem eingangs angeführten Verfahren, bei welchem bei gleicher Anzahl und Dimensionierung der Hohlkörper und bei gleicher Umlaufzahl in 1 Minute aus 1 l 20 %iger Luft neben zahlreichen gesondert aufzuarbeitenden Zwischenfraktionen nur $^1/_{32}$ l 25 %ige Luft gewonnen wird, so erkennt man sofort, daß das hier mitgeteilte Verfahren unvergleichlich vorteilhafter arbeitet: Es arbeitet mit einem Minimum an Ausgangsmaterial und liefert in einem Arbeitsgang sofort die stärkst angereicherten bzw. verarmten Fraktionen, ohne daß es notwendig wäre, Zwischenfraktionen zu entnehmen. Die genannten Vorteile wirken sich um so stärker aus, je zahlreicher die Hohlräume sind, die für die Erzielung eines bestimmten Trennungsgrades in Anwendung genommen werden müssen.

Mit der bisherigen Beschreibung an Hand der Vorrichtung Fig. 1 und des Zahlenbeispiels ist das Hauptkennzeichen des mitzuteilenden Trennverfahrens, nämlich der Kreislauf des Gemisches im Innern des Hohlkörpersystems, in den wesentlichsten Zügen erläutert. Die Geschwindigkeit, mit welcher das Gemisch dabei in Kreislauf zu halten ist, damit tatsächlich jeweils die günstigste Trennwirkung erzielt wird, wird von Fall zu Fall recht verschieden sein. Das rührt namentlich daher, daß die durch das Schwerefeld verursachte teilweise Entmischung im Einzelhohlkörper, die zu der Anreicherung des schweren bzw. leichten Gasbestandteils in den äußeren bzw. zentralen Hohlraumbezirken führt, durch Diffusion erfolgt; der Ablauf dieses Diffusionsvorganges erfordert aber einen gewissen Zeitaufwand, dessen Größe von den Abmessungen des Hohlkörpers und von der Diffusionsgeschwindigkeit, also von der speziellen Natur des Gasgemisches und von dessen Druck abhängig ist. Die Zeitdauer des Diffusionsvorganges und die Größe der Hohlkörper bestimmen die zulässige Zirkulationsgeschwindigkeit. Diese wird zweckmäßig so gewählt, daß die Verweilzeit des Gemisches in einem Hohlkörper gerade noch für den Ablauf des Diffusionsvorganges in diesem Hohlkörper ausreichend ist. Wird mit höherer Zirkulationsgeschwindigkeit gearbeitet, so werden die einzelnen Fraktionen zu rasch aus dem Hohlkörper ausgespült, was zur Folge hat, daß die Trennwirkung des einzelnen Hohlkörpers hinter der maximal möglichen Wirkung (Größe δ in Fig. 1) zurückbleibt.

Entsprechend der unterschiedlichen Zirkulationsgeschwindigkeit ist auch der erzielbare Durchsatz durch das Hohlkörpersystem, d. h. die bei kontinuierlicher Arbeitsweise pro Minute in stark angereicherte Fraktionen zerlegbare Gasmenge von Fall zu Fall recht verschieden. Wie das Zahlenbeispiel zeigte, macht der Durchsatz einen bestimmten Bruchteil der Zirkulationsgeschwindigkeit aus, der zahlenmäßig annähernd gleich der reziproken Anzahl der vorgesehenen Hohlkörper ist. Bei einer gegebenen Vorrichtung kann daher der Durchsatz durch Erhöhung der Zirkulationsgeschwindigkeit erhöht werden. Wird dabei jedoch die vorhin gekennzeichnete Normalgeschwindigkeit der Zirkulation überschritten, so kann die so erzielbare Umsatzsteigerung, wie gesagt, nur auf Kosten der Trenngüte erkauft werden.

Im Gegensatz zu den vorhin genannten Diffusionsvorgängen im Schwerefeld sind Diffusionsvorgänge, die durch die verschiedene Zusammensetzung der Gasgemische an den Enden der die Hohlkörper verbindenden Leitungen in diesen Leitungen ausgelöst und unter Umständen, nämlich bei besonders weiten und kurzen Rohrverbindungen, im Sinne eines Rückausgleichs der bereits erzielten Anreicherungsgrade wirksam werden können, selbstverständlich unerwünscht. Aus diesem Grunde wird die Dimensionierung der Leitungen zweckmäßigerweise so gewählt, daß in den Leitungen der Gastransport infolge Strömung den Transport infolge Diffusion stark überwiegt und auf diese Weise eine Rückdiffusion durch die Leitungen hindurch praktisch ausgeschlossen ist.

Andererseits ist es selbstverständlich notwendig, durch geeignete Anordnung oder Form der Ein- und Ausmündungsöffnungen der Leitungen dafür zu sorgen, daß das in einen Hohlkörper einströmende Gas nicht Gelegenheit hat, diesen sofort durch eine unmittelbar benachbarte Öffnung wieder zu verlassen, ohne zuvor an dem Trennprozeß im Hohlkörper teilgenommen zu haben. In andern Worten: Es muß dafür gesorgt sein, daß in den Hohlräumen keine toten Winkel auftreten, die von den die Hohlkörper durchsetzenden Gasströmen überhaupt nicht erfaßt werden. Im Falle des Beispiels Fig. 1, bei welchem besonders flache Hohlkörper vorgesehen sind, ist dem besagten Punkte in der Weise Rechnung getragen, daß die Einmündungen und Ausmündungen jeweils um 180° auf dem Umfang versetzt angebracht sind (vgl. z. B. Einmündung i_{II} und Ausmündung h_{II}). Falls die Hohlkörper sehr hoch (lang) oder mehrere Öffnungen auf den ganzen Umfang verteilt sind, ist diese Versetzung auf dem Umfang natürlich nicht nötig.

Das Verfahren ist im übrigen, wie im folgenden gezeigt werden soll, der verschiedensten Abwandlungen fähig.

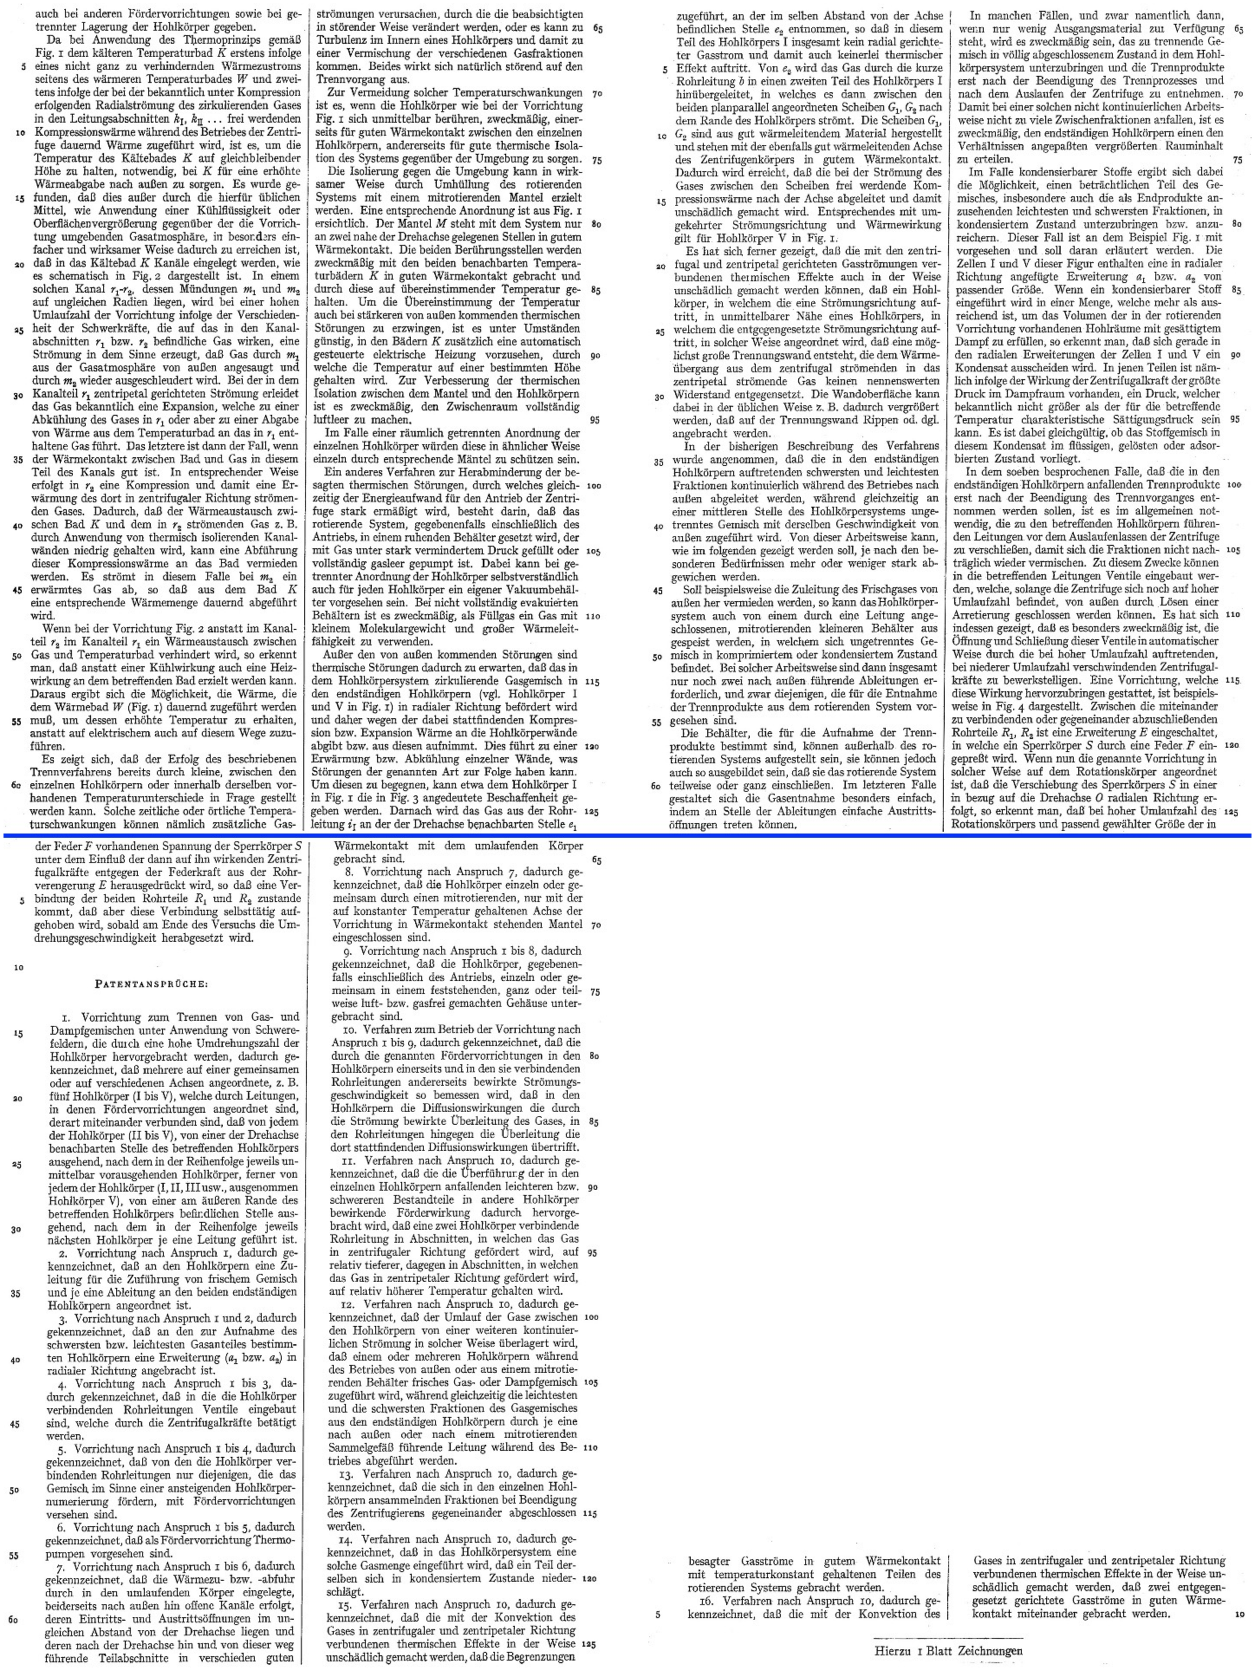
Es wurde bereits erwähnt, daß die Hohlkörper anstatt wie in Fig. 1 zu einer Einheit zusammengefaßt auch selbständig ausgebildet, d. h. auf getrennten Lagern gelagert werden können. In solchem Falle sind dann die verschiedenen Leitungen, die für die beschriebene Überleitung der in den einzelnen Hohlkörpern anfallenden Fraktionen bestimmt sind, passend, z. B. in den Zentrifugenachsen zu verlegen und durch gasdichte Durchführungen miteinander in Verbindung zu bringen. Hierbei ist dann die Möglichkeit gegeben, die einzelnen Hohlkörper mit unterschiedlichen Umlaufzahlen laufen zu lassen, was z. B. bei unterschiedlichen Außenabmessungen der Hohlkörper von Interesse sein kann. Ob dabei die Drehachse für alle Hohlkörper gemeinsam ist oder nicht, ist für die erzielbare Wirkung selbstverständlich belanglos.

Die für die Förderung des Gases in den die einzelnen Hohlkörper verbindenden Leitungen erforderlichen Fördervorrichtungen können ebenfalls sehr verschieden sein. In dem Falle, daß die Hohlkörper einzeln gelagert und die Leitungen daher streckenweise außerhalb des rotierenden Systems geführt sind, kann die Gasförderung durch beliebige der bekannten Pump- oder Ventilationsvorrichtungen (Kreislaufpumpen), die in die nicht mitrotierenden Leitungsabschnitte einzubauen sind, bewerkstelligt werden. In dem Falle, daß die Hohlkörper wie in Fig. 1 ein starres Ganzes bilden und die einzelnen Leitungen nicht nach außen geführt sind, ist es selbstverständlich notwendig, die Fördervorrichtungen in das rotierende System selber einzubauen. Hierfür ist ein Teil der bekannten Fördervorrichtungen, und zwar namentlich diejenigen, die durch Drehen einer Antriebswelle in Betrieb zu setzen sind, durchaus geeignet. Wenn dabei die betreffenden Fördervorrichtungen so angeordnet werden, daß deren Antriebswellen in die Drehachse der Zentrifuge zu liegen kommen, so kann das Drehen der Antriebswellen (relativ zum Zentrifugenkörper) dadurch bewerkstelligt werden, daß auf diese Antriebswellen von außen her, z. B. auf mechanischem oder magnetischem Wege, eine Bremswirkung ausgeübt wird; ein besonderer Antrieb für die Fördervorrichtung auf dem Zentrifugenkörper ist dann nicht erforderlich.

In besonders einfacher Weise läßt sich jedoch der erforderliche Gaskreislauf, wie an Hand des Beispiels Fig. 1 erläutert werden soll, durch eine sog. Thermosiphonwirkung hervorbringen. Diese wird dadurch hervorgebracht, daß eine zwei Hohlkörper, z. B. I und II, verbindende Leitung i_I-k_I-w_{II}-h_{II} in einem Abschnitt k_I, in welchem das Gas in zentrifugaler Richtung befördert werden soll, auf relativ tieferer Temperatur, in einem Abschnitt w_{II}, in welchem das Gas in zentripetaler Richtung befördert werden soll, auf relativ höherer Temperatur gehalten wird. Zu diesem Zwecke sind bei dem Zentrifugenkörper Fig. 1 zwei bzw. zwei mal zwei thermisch voneinander abisolierte Temperaturbäder K und W (Kupferblöcke, Flüssigkeitsbehälter od. dgl.) vorgesehen, in welche die Leitungen in der aus der Figur ersichtlichen Weise eingelegt sind und deren eines, W, durch eine beispielsweise elektrische Heizung bei einer etwas erhöhten Temperatur gehalten wird. Eine solche Vorrichtung wirkt, wenn der Zentrifugenkörper um die Achse O rotiert, als Thermopumpe, die das Gas in der durch Pfeile angedeuteten Richtung in Bewegung setzt. Die Förderwirkung kommt dabei dadurch zustande, daß das Gas in dem wärmeren Leitungsabschnitt, z. B. w_{II}, eine geringere Dichte annimmt als in dem damit kommunizierenden kälteren Leitungsabschnitt k_I, was dann weiter zur Folge hat, daß das Gas unter der Wirkung der starken Zentrifugalkräfte einen kräftigen Antrieb in der angegebenen Richtung erfährt. Die Größe der Antriebskraft läßt sich in bekannter Weise ermitteln und damit auch, wenn die Abmessungen der Leitungen gegeben sind, die Fördergeschwindigkeit.

Fig. 1 läßt erkennen, daß die Einschaltung von Fördervorrichtungen allein in diejenigen Leitungen, die für die Überleitung des Gasgemisches von Hohlkörper zu Hohlkörper in der Richtung einer abnehmenden Hohlkörpernumerierung vorgesehen sind, bereits ausreichend ist, um auch den (zur Vollendung des früher beschriebenen Kreislaufs) erforderlichen Gasstrom in der Richtung einer ansteigenden Hohlkörpernumerierung hervorzubringen. Das rührt daher, daß Fördervorrichtungen, die gemäß Fig. 1 eingeschaltet sind, von Hohlkörper V bis Hohlkörper I stufenweise ansteigende Gasdrücke hervorrufen, unter deren Wirkung das Gas dann von selbst durch die Leitungen s_I, s_{II} … von Hohlkörper I nach II, von II nach III usw. wieder zurückströmt. In den Leitungen s_I bis s_{IV} sind daher besondere Fördervorrichtungen entbehrlich. Diese Vereinfachungsmöglichkeit ist in gleicher Weise

Figure D.143: Patent on gas centrifuges filed by Werner Kuhn and Hans Martin in 1938 [German Patent DE 906,094].



auch bei anderen Fördervorrichtungen sowie bei getrennter Lagerung der Hohlkörper gegeben.

Da bei Anwendung des Thermoprinzips gemäß Fig. 1 dem kälteren Temperaturbad K erstens infolge eines nicht ganz zu verhindernden Wärmezustroms seitens des wärmeren Temperaturbades W und zweitens infolge der bei der bekanntlich unter Kompression erfolgenden Radialströmung des zirkulierenden Gases in den Leitungsabschnitten k_{I}, k_{II} ... frei werdenden Kompressionswärme während des Betriebes der Zentrifuge dauernd Wärme zugeführt wird, ist es, um die Temperatur des Kältebades K auf gleichbleibender Höhe zu halten, notwendig, bei K für eine erhöhte Wärmeabgabe nach außen zu sorgen. Es wurde gefunden, daß dies außer durch die hierfür üblichen Mittel, wie Anwendung einer Kühlflüssigkeit oder Oberflächenvergrößerung gegenüber der die Vorrichtung umgebenden Gasatmosphäre, in besonders einfacher und wirksamer Weise dadurch zu erreichen ist, daß in das Kältebad K Kanäle eingelegt werden, wie es schematisch in Fig. 2 dargestellt ist. In einem solchen Kanal r_1-r_2, dessen Mündungen m_1 und m_2 auf ungleichen Radien liegen, wird bei einer hohen Umlaufzahl der Vorrichtung infolge der Verschiedenheit der Schwerkräfte, die auf das in den Kanalabschnitten r_1 bzw. r_2 befindliche Gas wirken, eine Strömung in dem Sinne erzeugt, daß Gas durch m_1 aus der Gasatmosphäre von außen angesaugt und durch m_2 wieder ausgeschleudert wird. Bei der in dem Kanalteil r_1 zentripetal gerichteten Strömung erleidet das Gas bekanntlich eine Expansion, welche zu einer Abkühlung des Gases in r_1 oder aber zu einer Abgabe von Wärme aus dem Temperaturbad an das in r_1 enthaltene Gas führt. Das letztere ist dann der Fall, wenn der Wärmekontakt zwischen Bad und Gas in diesem Teil des Kanals gut ist. In entsprechender Weise erfolgt in r_2 eine Kompression und damit eine Erwärmung des dort in zentrifugaler Richtung strömenden Gases. Dadurch, daß der Wärmeaustausch zwischen Bad K und dem in r_2 strömenden Gas z. B. durch Anwendung von thermisch isolierenden Kanalwänden niedrig gehalten wird, kann eine Abführung dieser Kompressionswärme an das Bad vermieden werden. Es strömt in diesem Falle bei m_2 ein erwärmtes Gas ab, so daß aus dem Bad K eine entsprechende Wärmemenge dauernd abgeführt wird.

Wenn bei der Vorrichtung Fig. 2 anstatt im Kanalteil r_2 im Kanalteil r_1 ein Wärmeaustausch zwischen Gas und Temperaturbad verhindert wird, so erkennt man, daß anstatt einer Kühlwirkung auch eine Heizwirkung an dem betreffenden Bad erzielt werden kann. Daraus ergibt sich die Möglichkeit, die Wärme, die dem Wärmebad W (Fig. 1) dauernd zugeführt werden muß, um dessen erhöhte Temperatur zu erhalten, anstatt auf elektrischem auch auf diesem Wege zuzuführen.

Es zeigt sich, daß der Erfolg des beschriebenen Trennverfahrens bereits durch kleine, zwischen den einzelnen Hohlkörpern oder innerhalb derselben vorhandenen Temperaturunterschiede in Frage gestellt werden kann. Solche zeitliche oder örtliche Temperaturschwankungen können nämlich zusätzliche Gasströmungen verursachen, durch die die beabsichtigten in störender Weise verändert werden, oder es kann zu Turbulenz im Innern eines Hohlkörpers und damit zu einer Vermischung der verschiedenen Gasfraktionen kommen. Beides wirkt sich natürlich störend auf den Trennvorgang aus.

Zur Vermeidung solcher Temperaturschwankungen ist es, wenn die Hohlkörper wie bei der Vorrichtung Fig. 1 sich unmittelbar berühren, zweckmäßig, einerseits für guten Wärmekontakt zwischen den einzelnen Hohlkörpern, andererseits für gute thermische Isolation des Systems gegenüber der Umgebung zu sorgen.

Die Isolierung gegen die Umgebung kann in wirksamer Weise durch Umhüllung des rotierenden Systems mit einem mitrotierenden Mantel erzielt werden. Eine entsprechende Anordnung ist aus Fig. 1 ersichtlich. Der Mantel M steht mit dem System nur an zwei nahe der Drehachse gelegenen Stellen in gutem Wärmekontakt. Die beiden Berührungsstellen werden zweckmäßig mit den beiden benachbarten Temperaturbädern K in guten Wärmekontakt gebracht und durch diese auf übereinstimmender Temperatur gehalten. Um die Übereinstimmung der Temperatur auch bei stärkeren von außen kommenden thermischen Störungen zu erzwingen, ist es unter Umständen günstig, in den Bädern K zusätzlich eine automatisch gesteuerte elektrische Heizung vorzusehen, durch welche die Temperatur auf einer bestimmten Höhe gehalten wird. Zur Verbesserung der thermischen Isolation zwischen dem Mantel und den Hohlkörpern ist es zweckmäßig, den Zwischenraum vollständig luftleer zu machen.

Im Falle einer räumlich getrennten Anordnung der einzelnen Hohlkörper würden diese in ähnlicher Weise einzeln durch entsprechende Mäntel zu schützen sein.

Ein anderes Verfahren zur Herabminderung der besagten thermischen Störungen, durch welches gleichzeitig der Energieaufwand für den Antrieb der Zentrifuge stark ermäßigt wird, besteht darin, daß das rotierende System, gegebenenfalls einschließlich des Antriebs, in einem ruhenden Behälter gesetzt wird, der mit Gas unter stark vermindertem Druck gefüllt oder vollständig gasleer gepumpt ist. Dabei kann bei getrennter Anordnung der Hohlkörper selbstverständlich auch für jeden Hohlkörper ein eigener Vakuumbehälter vorgesehen sein. Bei nicht vollständig evakuierten Behältern ist es zweckmäßig, als Füllgas ein Gas mit kleinem Molekulargewicht und großer Wärmeleitfähigkeit zu verwenden.

Außer den von außen kommenden Störungen sind thermische Störungen dadurch zu erwarten, daß das in dem Hohlkörpersystem zirkulierende Gasgemisch in den endständigen Hohlkörpern (vgl. Hohlkörper I und V in Fig. 1) in radialer Richtung befördert wird und daher wegen der dabei stattfindenden Kompression bzw. Expansion Wärme an die Hohlkörperwände abgibt bzw. aus diesen aufnimmt. Dies führt zu einer Erwärmung bzw. Abkühlung einzelner Wände, was Störungen der genannten Art zur Folge haben kann. Um diesen zu begegnen, kann etwa dem Hohlkörper I in Fig. 1 die in Fig. 3 angedeutete Beschaffenheit gegeben werden. Darnach wird das Gas aus der Rohrleitung i_{I} an der der Drehachse benachbarten Stelle e_1 zugeführt, an der im selben Abstand von der Achse befindlichen Stelle e_2 entnommen, so daß in diesem Teil des Hohlkörpers I insgesamt kein radial gerichteter Gasstrom und damit auch keinerlei thermischer Effekt auftritt. Von e_2 wird das Gas durch die kurze Rohrleitung b in einen zweiten Teil des Hohlkörpers I hinübergeleitet, in welches es dann zwischen den beiden planparallel angeordneten Scheiben G_1, G_2 nach dem Rande des Hohlkörpers strömt. Die Scheiben G_1, G_2 sind aus gut wärmeleitendem Material hergestellt und stehen mit der ebenfalls gut wärmeleitenden Achse des Zentrifugenkörpers in gutem Wärmekontakt. Dadurch wird erreicht, daß die bei der Strömung des Gases zwischen den Scheiben frei werdende Kompressionswärme nach der Achse abgeleitet und damit unschädlich gemacht wird. Entsprechendes mit umgekehrter Strömungsrichtung und Wärmewirkung gilt für Hohlkörper V in Fig. 1.

Es hat sich ferner gezeigt, daß die mit den zentrifugal und zentripetal gerichteten Gasströmungen verbundenen thermischen Effekte auch in der Weise unschädlich gemacht werden können, daß ein Hohlkörper, in welchem die eine Strömungsrichtung auftritt, in unmittelbarer Nähe eines Hohlkörpers, in welchem die entgegengesetzte Strömungsrichtung auftritt, in solcher Weise angeordnet wird, daß eine möglichst große Trennungswand entsteht, die dem Wärmeübergang aus dem zentrifugal strömenden in das zentripetal strömende Gas keinen nennenswerten Widerstand entgegensetzt. Die Wandoberfläche kann dabei in der üblichen Weise z. B. dadurch vergrößert werden, daß auf der Trennungswand Rippen od. dgl. angebracht werden.

In der bisherigen Beschreibung des Verfahrens wurde angenommen, daß die in den endständigen Hohlkörpern auftretenden schwersten und leichtesten Fraktionen kontinuierlich während des Betriebes nach außen abgeleitet werden, während gleichzeitig an einer mittleren Stelle des Hohlkörpersystems ungetrenntes Gemisch mit derselben Geschwindigkeit von außen zugeführt wird. Von dieser Arbeitsweise kann, wie im folgenden gezeigt werden soll, je nach den besonderen Bedürfnissen mehr oder weniger stark abgewichen werden.

Soll beispielsweise die Zuleitung des Frischgases von außen her vermieden werden, so kann das Hohlkörpersystem auch von einem durch eine Leitung angeschlossenen, mitrotierenden kleineren Behälter aus gespeist werden, in welchem sich ungetrenntes Gemisch in komprimiertem oder kondensiertem Zustand befindet. Bei solcher Arbeitsweise sind dann insgesamt nur noch zwei nach außen führende Ableitungen erforderlich, und zwar diejenigen, die für die Entnahme der Trennprodukte aus dem rotierenden System vorgesehen sind.

Die Behälter, die für die Aufnahme der Trennprodukte bestimmt sind, können außerhalb des rotierenden Systems aufgestellt sein, sie können jedoch auch so ausgebildet sein, daß sie das rotierende System teilweise oder ganz einschließen. Im letzteren Falle gestaltet sich die Gasentnahme besonders einfach, indem an Stelle der Ableitungen einfache Austrittsöffnungen treten können.

In manchen Fällen, und zwar namentlich dann, wenn nur wenig Ausgangsmaterial zur Verfügung steht, wird es zweckmäßig sein, das zu trennende Gemisch in völlig abgeschlossenem Zustand in dem Hohlkörpersystem unterzubringen und die Trennprodukte erst nach der Beendigung des Trennprozesses und nach dem Auslaufen der Zentrifuge zu entnehmen. Damit bei einer solchen nicht kontinuierlichen Arbeitsweise nicht zu viele Zwischenfraktionen anfallen, ist es zweckmäßig, den endständigen Hohlkörpern einen den Verhältnissen angepaßten vergrößerten Rauminhalt zu erteilen.

Im Falle kondensierbarer Stoffe ergibt sich dabei die Möglichkeit, einen beträchtlichen Teil des Gemisches, insbesondere auch die als Endprodukte anzusehenden leichtesten und schwersten Fraktionen, in kondensiertem Zustand unterzubringen bzw. anzureichern. Dieser Fall ist an dem Beispiel Fig. 1 mit vorgesehen und soll daran erläutert werden. Die Zellen I und V dieser Figur enthalten eine in radialer Richtung angefügte Erweiterung a_1 bzw. a_2 von passender Größe. Wenn ein kondensierbarer Stoff eingeführt wird in einer Menge, welche mehr als ausreichend ist, um das Volumen der in der rotierenden Vorrichtung vorhandenen Hohlräume mit gesättigtem Dampf zu erfüllen, so erkennt man, daß sich gerade in den radialen Erweiterungen der Zellen I und V ein Kondensat ausscheiden wird. In jenen Teilen ist nämlich infolge der Wirkung der Zentrifugalkraft der größte Druck im Dampfraum vorhanden, ein Druck, welcher bekanntlich nicht größer als der für die betreffende Temperatur charakteristische Sättigungsdruck sein kann. Es ist dabei gleichgültig, ob das Stoffgemisch in diesem Kondensat im flüssigen, gelösten oder adsorbierten Zustand vorliegt.

In dem soeben besprochenen Falle, daß die in den endständigen Hohlkörpern anfallenden Trennprodukte erst nach der Beendigung des Trennvorganges entnommen werden sollen, ist es im allgemeinen notwendig, die zu den betreffenden Hohlkörpern führenden Leitungen vor dem Auslaufenlassen der Zentrifuge zu verschließen, damit sich die Fraktionen nicht nachträglich wieder vermischen. Zu diesem Zwecke können in die betreffenden Leitungen Ventile eingebaut werden, welche, solange die Zentrifuge sich noch auf hoher Umlaufzahl befindet, von außen durch Lösen einer Arretierung geschlossen werden können. Es hat sich indessen gezeigt, daß es besonders zweckmäßig ist, die Öffnung und Schließung dieser Ventile in automatischer Weise durch die bei hoher Umlaufzahl auftretenden, bei niederer Umlaufzahl verschwindenden Zentrifugalkräfte zu bewerkstelligen. Eine Vorrichtung, welche diese Wirkung hervorzubringen gestattet, ist beispielsweise in Fig. 4 dargestellt. Zwischen die miteinander zu verbindenden oder gegeneinander abzuschließenden Rohrteile R_1, R_2 ist eine Erweiterung E eingeschaltet, in welche ein Sperrkörper S durch eine Feder F eingepreßt wird. Wenn nun die genannte Vorrichtung in solcher Weise auf dem Rotationskörper angeordnet ist, daß die Verschiebung des Sperrkörpers S in einer in bezug auf die Drehachse O radialen Richtung erfolgt, so erkennt man, daß bei hoher Umlaufzahl des Rotationskörpers und passend gewählter Größe der in der Feder F vorhandenen Spannung der Sperrkörper S unter dem Einfluß der dann auf ihn wirkenden Zentrifugalkräfte entgegen der Federkraft aus der Rohrverengerung E herausgedrückt wird, so daß eine Verbindung der beiden Rohrteile R_1 und R_2 zustande kommt, daß aber diese Verbindung selbsttätig aufgehoben wird, sobald am Ende des Versuchs die Umdrehungsgeschwindigkeit herabgesetzt wird.

PATENTANSPRÜCHE:

1. Vorrichtung zum Trennen von Gas- und Dampfgemischen unter Anwendung von Schwerefeldern, die durch eine hohe Umdrehungszahl der Hohlkörper hervorgebracht werden, dadurch gekennzeichnet, daß mehrere auf einer gemeinsamen oder auf verschiedenen Achsen angeordnete, z. B. fünf Hohlkörper (I bis V), welche durch Leitungen, in denen Fördervorrichtungen angeordnet sind, derart miteinander verbunden sind, daß von jedem der Hohlkörper (II bis V), von einer der Drehachse benachbarten Stelle des betreffenden Hohlkörpers ausgehend, nach dem in der Reihenfolge jeweils unmittelbar vorausgehenden Hohlkörper, ferner von jedem der Hohlkörper (I, II, III usw., ausgenommen Hohlkörper V), von einer am äußeren Rande des betreffenden Hohlkörpers befindlichen Stelle ausgehend, nach dem in der Reihenfolge jeweils nächsten Hohlkörper je eine Leitung geführt ist.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß an den Hohlkörpern eine Zuleitung für die Zuführung von frischem Gemisch und je eine Ableitung an den beiden endständigen Hohlkörpern angeordnet ist.

3. Vorrichtung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß an den zur Aufnahme des schwersten bzw. leichtesten Gasanteiles bestimmten Hohlkörpern eine Erweiterung (a_1 bzw. a_2) in radialer Richtung angebracht ist.

4. Vorrichtung nach Anspruch 1 bis 3, dadurch gekennzeichnet, daß in die die Hohlkörper verbindenden Rohrleitungen Ventile eingebaut sind, welche durch die Zentrifugalkräfte betätigt werden.

5. Vorrichtung nach Anspruch 1 bis 4, dadurch gekennzeichnet, daß von den die Hohlkörper verbindenden Rohrleitungen nur diejenigen, die das Gemisch im Sinne einer ansteigenden Hohlkörpernumerierung fördern, mit Fördervorrichtungen versehen sind.

6. Vorrichtung nach Anspruch 1 bis 5, dadurch gekennzeichnet, daß als Fördervorrichtung Thermopumpen vorgesehen sind.

7. Vorrichtung nach Anspruch 1 bis 6, dadurch gekennzeichnet, daß die Wärmezu- bzw. -abfuhr durch in den umlaufenden Körper eingelegte, beiderseits nach außen hin offene Kanäle erfolgt, deren Eintritts- und Austrittsöffnungen im ungleichen Abstand von der Drehachse liegen und deren nach der Drehachse hin und von dieser weg führende Teilabschnitte in verschieden guten Wärmekontakt mit dem umlaufenden Körper gebracht sind.

8. Vorrichtung nach Anspruch 7, dadurch gekennzeichnet, daß die Hohlkörper einzeln oder gemeinsam durch einen mitrotierenden, nur mit der auf konstanter Temperatur gehaltenen Achse der Vorrichtung in Wärmekontakt stehenden Mantel eingeschlossen sind.

9. Vorrichtung nach Anspruch 1 bis 8, dadurch gekennzeichnet, daß die Hohlkörper, gegebenenfalls einschließlich des Antriebs, einzeln oder gemeinsam in einem feststehenden, ganz oder teilweise luft- bzw. gasfrei gemachten Gehäuse untergebracht sind.

10. Verfahren zum Betrieb der Vorrichtung nach Anspruch 1 bis 9, dadurch gekennzeichnet, daß die durch die genannten Fördervorrichtungen in den Hohlkörpern einerseits und in den sie verbindenden Rohrleitungen andererseits bewirkte Strömungsgeschwindigkeit so bemessen wird, daß in den Hohlkörpern die Diffusionswirkungen die durch die Strömung bewirkte Überleitung des Gases, in den Rohrleitungen hingegen die Überleitung die dort stattfindenden Diffusionswirkungen übertrifft.

11. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß die die Überführung der in den einzelnen Hohlkörpern anfallenden leichteren bzw. schwereren Bestandteile in andere Hohlkörper bewirkende Förderwirkung dadurch hervorgebracht wird, daß eine zwei Hohlkörper verbindende Rohrleitung in Abschnitten, in welchen das Gas in zentrifugaler Richtung gefördert wird, auf relativ tieferer, dagegen in Abschnitten, in welchen das Gas in zentripetaler Richtung gefördert wird, auf relativ höherer Temperatur gehalten wird.

12. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß der Umlauf der Gase zwischen den Hohlkörpern von einer weiteren kontinuierlichen Strömung in solcher Weise überlagert wird, daß einem oder mehreren Hohlkörpern während des Betriebes von außen oder aus einem mitrotierenden Behälter frisches Gas- oder Dampfgemisch zugeführt wird, während gleichzeitig die leichtesten und die schwersten Fraktionen des Gasgemisches aus den endständigen Hohlkörpern durch je eine nach außen oder nach einem mitrotierenden Sammelgefäß führende Leitung während des Betriebes abgeführt werden.

13. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß die sich in den einzelnen Hohlkörpern ansammelnden Fraktionen bei Beendigung des Zentrifugierens gegeneinander abgeschlossen werden.

14. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß in das Hohlkörpersystem eine solche Gasmenge eingeführt wird, daß ein Teil derselben sich in kondensiertem Zustande niederschlägt.

15. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß die mit der Konvektion des Gases in zentrifugaler und zentripetaler Richtung verbundenen thermischen Effekte in der Weise unschädlich gemacht werden, daß die Begrenzungen besagter Gasströme in gutem Wärmekontakt mit temperaturkonstant gehaltenen Teilen des rotierenden Systems gebracht werden.

16. Verfahren nach Anspruch 10, dadurch gekennzeichnet, daß die mit der Konvektion des Gases in zentrifugaler und zentripetaler Richtung verbundenen thermischen Effekte in der Weise unschädlich gemacht werden, daß zwei entgegengesetzt gerichtete Gasströme in guten Wärmekontakt miteinander gebracht werden.

Multiplikationsverfahren zur Trennung von Gasgemischen, insbesondere bei Anwendung von Schwerefeldern.

Von

Hans Martin und **Werner Kuhn.**

(Mit 16 Abbildungen im Text.)

(Eingegangen am 2. 5. 41.)

Es wird ein Multiplikationsverfahren angegeben, mit dessen Hilfe es allgemein möglich ist, in Gasgemischen (Isotopengemischen) auftretende schwache Entmischungseffekte, wie sie beispielsweise bei Einwirkung eines Gravitationsfeldes oder eines Temperaturgefälles beobachtet werden (Einzeleffekte), grundsätzlich beliebig stark zu vervielfachen und damit eine im Einzeleffekt nur unvollkommene Zerlegung eines Gemisches in beliebigem Maße zu vervollständigen. Es ist ein wesentlicher Bestandteil des Verfahrens, daß das Gemisch innerhalb des Hohlraumes, in welchen es eingeschlossen ist, in bestimmter Weise zirkuliert.

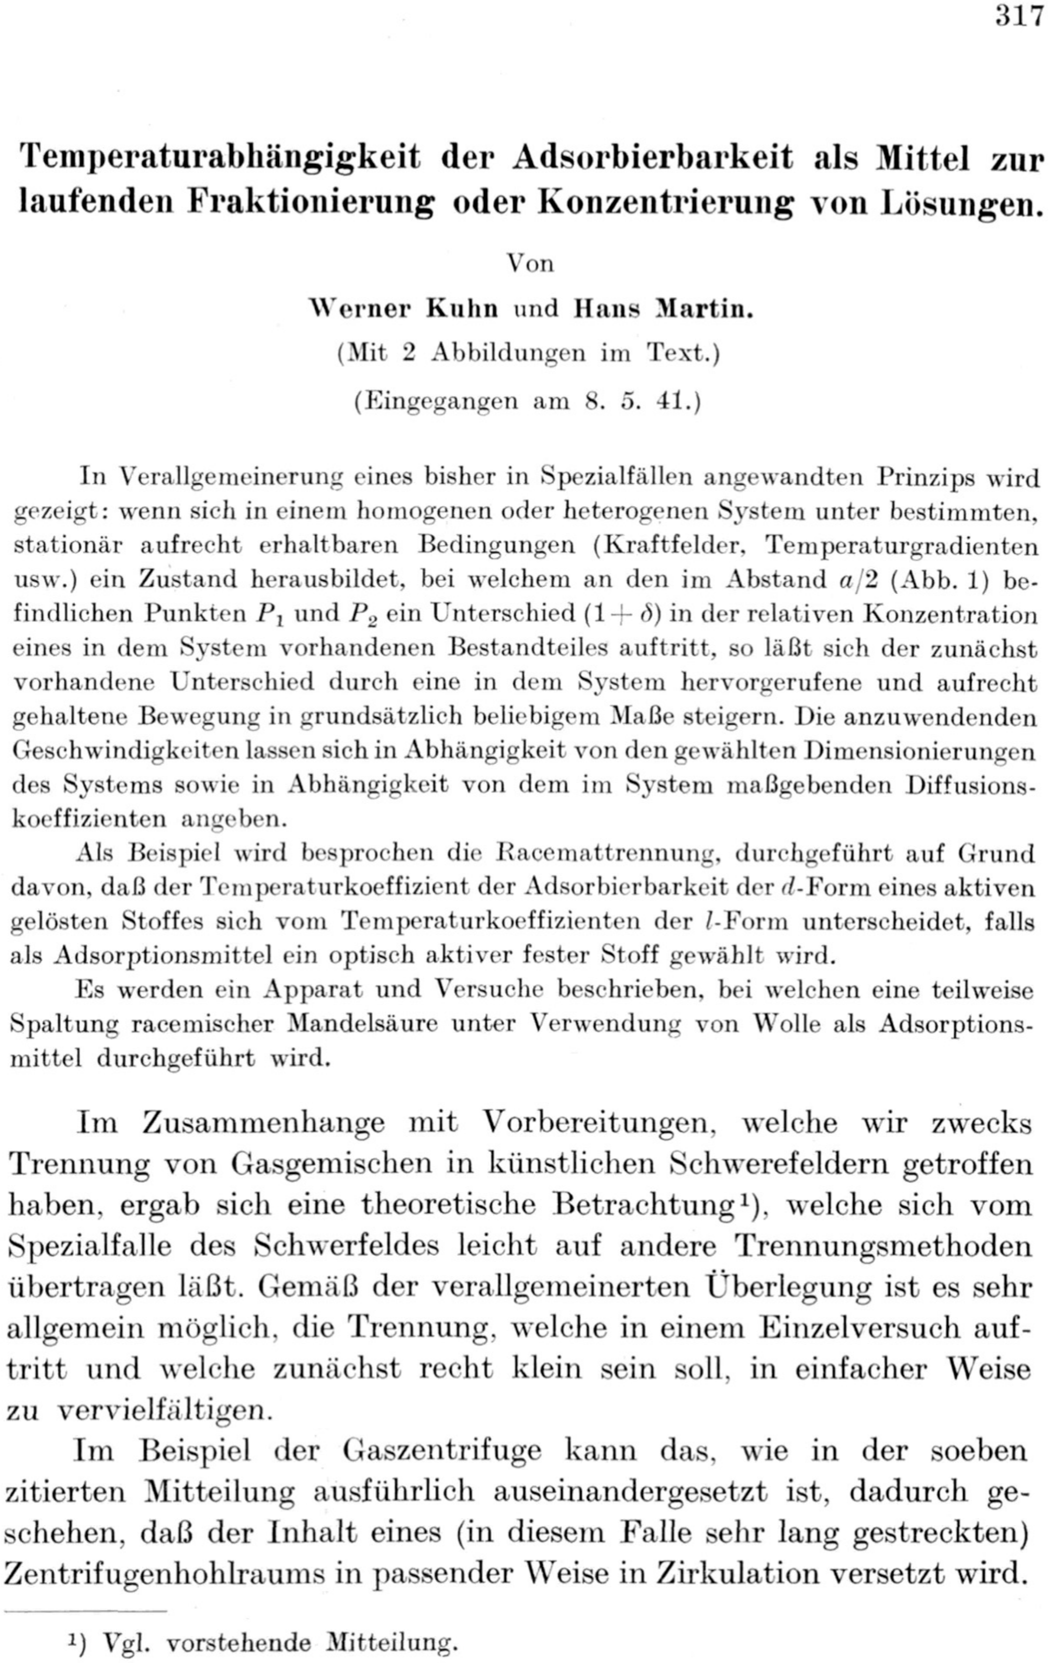
Den überwiegenden Raum in der vorliegenden Mitteilung nimmt die Besprechung der Grundlagen eines Gastrennverfahrens (I. bis III. Kapitel) ein, bei welchem der Einzeleffekt (der vervielfacht werden soll) durch ein starkes künstliches Schwerefeld (I. Kapitel) hervorgerufen wird. Das Schwerefeld wird in einem rasch umlaufenden Zentrifugenkörper erzeugt. Es ergibt sich dabei als zufällige Besonderheit dieses Verfahrens, daß außer dem die Gastrennung verursachenden Einzeleffekt auch der für die Multiplikation dieses Effektes erforderliche Gasumlauf durch dasselbe Schwerefeld hervorgebracht werden kann (Thermokonvektion).

Der Frage nach einer zweckmäßigen Erzeugung der Gaszirkulation kommt nur mittelbare Bedeutung zu. Von grundlegender Bedeutung sind demgegenüber die Vorgänge, die sich als Folge dieser Gaszirkulation ergeben. Ihre Verfolgung an Hand des mitgeteilten Zentrifugenverfahrens führt auf ein Multiplikationsprinzip, welches allgemeinerer Anwendung fähig ist. Die Wirkungsweise dieses Prinzipes wird daher (im II. und III. Kapitel) besonders eingehend behandelt. Daneben werden auch speziellere Fragestellungen diskutiert, sofern diese einen wesentlichen Beitrag zur Lösung des Problems einer wirksamen Gastrennung im Schwerefeld darstellen. Hierher gehört außer der schon erwähnten Frage nach der Hervorbringung der Gaszirkulation insbesondere die Diskussion des Einflusses spezieller (zylindersymmetrischer) Hohlraumformen, wie sie durch die Notwendigkeit der Unterbringung des Gasgemisches in einem rasch rotierenden Zentrifugenkörper nahegelegt werden.

Das Multiplikationsprinzip läßt sich auf zweierlei Weise realisieren, und zwar entweder dadurch, daß der Gesamthohlraum durch Zwischenwände, die geeignete Öffnungen für die Gaszirkulation tragen, in eine größere Anzahl von Einzelkammern unterteilt wird (II. Kapitel), oder dadurch, daß dem Hohlraum eine besonders langgestreckte Form erteilt wird (III. Kapitel). Für den Trennvorgang

Z. physikal. Chem. Abt. A. Bd. 189, Heft 4|5. 16

Figure D.147: Hans Martin and Werner Kuhn. 1941. Multiplikationsverfahren zur Trennung von Gasgemischen, insbesondere bei Anwendung von Schwerefeldern. *Zeitschrift für Physikalische Chemie A* 189:219–316. First page is shown.



Temperaturabhängigkeit der Adsorbierbarkeit als Mittel zur laufenden Fraktionierung oder Konzentrierung von Lösungen.

Von

Werner Kuhn und **Hans Martin.**

(Mit 2 Abbildungen im Text.)

(Eingegangen am 8. 5. 41.)

In Verallgemeinerung eines bisher in Spezialfällen angewandten Prinzips wird gezeigt: wenn sich in einem homogenen oder heterogenen System unter bestimmten, stationär aufrecht erhaltbaren Bedingungen (Kraftfelder, Temperaturgradienten usw.) ein Zustand herausbildet, bei welchem an den im Abstand $a/2$ (Abb. 1) befindlichen Punkten P_1 und P_2 ein Unterschied $(1+\delta)$ in der relativen Konzentration eines in dem System vorhandenen Bestandteiles auftritt, so läßt sich der zunächst vorhandene Unterschied durch eine in dem System hervorgerufene und aufrecht gehaltene Bewegung in grundsätzlich beliebigem Maße steigern. Die anzuwendenden Geschwindigkeiten lassen sich in Abhängigkeit von den gewählten Dimensionierungen des Systems sowie in Abhängigkeit von dem im System maßgebenden Diffusionskoeffizienten angeben.

Als Beispiel wird besprochen die Racemattrennung, durchgeführt auf Grund davon, daß der Temperaturkoeffizient der Adsorbierbarkeit der d-Form eines aktiven gelösten Stoffes sich vom Temperaturkoeffizienten der l-Form unterscheidet, falls als Adsorptionsmittel ein optisch aktiver fester Stoff gewählt wird.

Es werden ein Apparat und Versuche beschrieben, bei welchen eine teilweise Spaltung racemischer Mandelsäure unter Verwendung von Wolle als Adsorptionsmittel durchgeführt wird.

Im Zusammenhange mit Vorbereitungen, welche wir zwecks Trennung von Gasgemischen in künstlichen Schwerefeldern getroffen haben, ergab sich eine theoretische Betrachtung¹), welche sich vom Spezialfalle des Schwerfeldes leicht auf andere Trennungsmethoden übertragen läßt. Gemäß der verallgemeinerten Überlegung ist es sehr allgemein möglich, die Trennung, welche in einem Einzelversuch auftritt und welche zunächst recht klein sein soll, in einfacher Weise zu vervielfältigen.

Im Beispiel der Gaszentrifuge kann das, wie in der soeben zitierten Mitteilung ausführlich auseinandergesetzt ist, dadurch geschehen, daß der Inhalt eines (in diesem Falle sehr lang gestreckten) Zentrifugenhohlraums in passender Weise in Zirkulation versetzt wird.

#4795-96. AZUSA. For Dix. With reference to your #2096.

With reference to the above message we shall do all we can to secure more information on this. We will be given considerable assistance when Hoyt reaches here. Hans Martin took over Kuhn's centrifuge projects at the University of Kiel. Kuhn says he believes this work is nearly finished, but no tests have yet been made. In June of this year the Kiel laboratories were still unharmed. Kuhn's centrifuge machine for the separation of isotopes attains a periferal velocity of approximately 300 meters per second. The resulting heat generated at such a speed was the main problem with which he was confronted. To overcome this difficulty he has encased the centrifuge in hydrogen at a pressure lower than that of the atmosphere which acts as a heat reducing agent.

SUBJECT: Status of Centrifuge Work at Kiel University.

[in Switzerland]

Following is answer of Kuhn to question concerning status of work on centrifuges at Kiel University:

entire

"Centrifuge projects at the University of Kiel have been taken over by Hans Martin. No tests have been made as yet but the work is just about through. There had been no damage to the Kiel laboratories as of June of this year. The centrifuge machine for the separation of isotopes reaches a periferal velocity of approximately 300 meters per second. The main problem to be solved in this project was the heat which this speed generated. This problem was met by encasing the centrifuge in hydrogen at a pressure lower than that of the atmosphere which acts as a heat reducing agent."

a Firma Anschütz u.Co,Kiel

1) Der Ihnen am 11.8.1941 erteilte Auftrag auf
Herstellung einer Ultrazentrifuge
zur Wehrmachtsauftragsnummer Wa F/I S Ho/071.1.3320/41/H
gehörig,ist ein

„Auftrag der Sonderstufe SS II/41 "

2) Wir bestätigen Ihnen ohne Einschränkung und Vorbehalt,dass die vorbezeichneten Gegenstände dazu bestimmt sind,unmittelbar oder in entsprechend weiter verarbeiteter Form als Bestandteil in ein Gerät einzugehen,das in der Sonderstufe geführt wird.

Eine gleichlautende Bestätigung unseres Auftraggebers besitzen wir in unseren Akten.

3) Wir bestätigen Ihnen,dass die in unserem Auftragsschreiben genannten Mengen und Liefertermine richtig sind,d.h. dass wir keine grösseren Mengen gefordert und keine kürzeren Termine gesetzt haben,als zur Durchführung unserer Produktiojsaufgabe unbedingt erforderlich sind.

4) Wir bestätigen ausserdem,dass die in den Ausführungsbestimmungen ADFW vom 31.12.40. enthaltenen Anordnungen bei der Weitergabe dieser Bestätigung eingehalten worden sind.
Wir sind uns bewusst,dass auf Grund des Straferlasses des Reichsmarschslls vom 20.9.40 falsche Angaben unter 1.bis 4. nach Massgabe der Ziffer II der 2. Verordnung zur Durchführung des Vierjahresplanes vom 5.11.36 mit Gefängnis bestraft werden und übernehmen Ihnen gegenüber die volle strafrechtliche Verantwortung,dass die unter Ziffer 1.bis 4. gemachten Angaben zu Recht bestehen.

9.12.1941.

Anschütz & Co. G.m.b.H.,
Kiel.
Postschliessfach

Ihre Zeichen: E.A.Dr.Bey/Rw. 80010.
Betr.: Herstellung einer Ultrazentrifuge, Oelkreislauf.

Sehr geehrter Herr Dr. Beyerle,

für Ihr Schreiben vom 5.12.d.Js. und die beigefügte Zeichnung danken wir Ihnen vielmals.

Soeben habe ich an die Fa. Leybold in Köln geschrieben um zu erfahren, ob das zu verwendene Apiezon-Oel in den von Ihnen vorgeschlagenen Pumpen verwendet werden kann und im Laufe der nächsten Wochen in grösseren Mengen lieferbar ist. Ausserdem habe ich mich auf Ihren Vorschlag an die Fa. Bosch in Stuttgart mit der Bitte um Beschleunigung Ihres Auftrages gewandt und darauf hingewiesen, dass die Lieferung der bestellten Luftpumpe und des zugehörigen Oelabscheiders für die Herstellung der Apparatur zeitbestimmend ist.

Im übrigen bin ich davon überzeugt, dass das Bosch-Material zweifellos die grösste Betriebssicherheit für den Oelkreislauf gewährleistet und mit Ihren Vorschlägen vollkommen einverstanden. Ich hoffe, dass die fehlenden Teile, auch die Leichtmetallegierung, auf deren Lieferung wir eigentlich warten, in nächster Zeit eintreffen werden, damit die Herstellung der Zentrifuge gute Fortschritte machen kann.

Mit ergebenen Grüssen und

Heil Hitler
Ihr

BETREFF

Herstellung einer Ultrazentrifuge, Oelkreislauf.

Für Ihr Schreiben vom 9.12.41 danken wir Ihnen bestens.

Die Firma Bosch G.m.b.H. teilt uns soeben mit, dass der in unserem Schema 03 21 02 - 1 /Schem.1 bei 3) vorgesehene Einzylinder-Luftpresser nicht geliefert werden kann, dass aber Verdichter der Type SV/DRB 160 R 12 4 Wochen nach Auftragseingang erhältlich seien.

Wir haben unsere frühere Bestellung Nr. 82 11 vom 23.11.41 zurückgezogen und anstelle dessen 2 Stück Verdichter der letztgenannten Type soeben mit der Bitte in Auftrag gegeben, die angegebene Lieferzeit von 4 Wochen einzuhalten. Gleichzeitig haben wir darauf hingewiesen, dass es sich dabei um ein Bauteil handelt, für dessen schnelle Lieferung Sie sich bereits an die Firma Bosch gewandt hatten.

Heil Hitler !

13.November 1941.

Betr.: Arbeitsbesprechung zum
Ultrazentrifugenbau in Hamburg
am 12. und 13.November 1941.

Anwesend : Harteck,Jensen,Martin,Groth,Suess,Knauer.

Auf der Sitzung in Berlin-Dahlem am 5.XI.41 war beschlossen worden,die Kieler und die Hamburger Arbeiten zum Zentrifugenbau zwecks Anreicherung der Isotopen des Präparats 38 nach einem gemeinsamen Plan auszurichten.Zu diesem Zwecke fanden in Hamburg am 12. und 13.November 1941 Arbeitsbesprechungen statt,die zur Beschlussfassung über folgende Punkte führten :

1) Die Antriebsvorrichtungen sollen von der Firma Anschütz und Co in Kiel gebaut werden.Die schon vorhandenen Konstruktionspläne sind sowohl für die Hamburger als auch für die Kieler Zwecke verwendbar.
2) Es wird vorgesehen,in Hamburg mit Zentrifugen ohne Kaskadenanordnung zu arbeiten,die bei gut nachweisbarem Trenneffekt (etwa 10 %) grosse Mengen liefern (einige 100 g pro Tag).
3) In Kiel sollen in der Zwischenzeit Rotoren vorbereitet werden, die bei einem Anreicherungsgrad von 50 % bis zu Verdoppelung mässige Mengen (einige g pro Tag) liefern,und bei denen unter
4) Verzicht auf grössere Trennwirkungen die Konstruktion möglichst vereinfacht wird.Diese Rotoren sollen so bemessen sein,dass sie unmittelbat an die vorgesehenen Antriebsvorrichtungen angschlossen werden können.
4)Der Antrieb ist anfänglich als Luftturbine vorgesehen.Inzwischen hat die Firma Anschütz bereits mit der Entwicklung des später zu verwendenden elektrischen Antriebs begonnen.Es ist zu hoffen, dass diese Entwicklungsarbeit so beschleunigt werden kann,dass die Kieler Zentrifuge von vornherein elektrisch angetrieben werden wird.
5) Der Zentrifugenbau bei der Firma Phywe,Göttingen soll vorläufig nicht mehr in Betracht gezogen werden.
6) Da die Lieferzeiten der Firma Anschütz mit etwa 3 Monaten angegeben werden,hängt die Fertigstellung der Zentrifuge wesentlich von der Liefergeschwindigkeit des Materials für die Rotorenkörper ab.Da anscheinend die Liefertermine der Firma Krupp,Essen, für Spezialstähle ungewöhnlich lang sind,wird die Herstellung aus Leichtmetallen in Betracht gezogen.

Herr Dr.Groth wird in den nächsten Tagen nach Berlin fahren,um die Materialfrage für die Rotoren zu regeln.

Wellenlagerung für Gaszentrifugen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 30. März 1949 an
Patenterteilung bekanntgemacht am 13. September 1951

Sowohl bei der Bestimmung des Molekulargewichtes von Eiweißkörpern, Viren und ähnlicher Großmoleküle durch Beobachtung ihrer Sedimentation in Flüssigkeiten bei Einwirkung starker Zentrifugalfelder als auch bei der Veränderung des Partialdruckverhältnisses von Gasgemischen durch Zentrifugieren ist die thermische Stabilisierung des rotierenden Systems ein wichtiger Teil der apparatebaulichen Aufgabe. In beiden Fällen kommt es nicht nur darauf an, das zu zentrifugierende Gut in gewissen Temperaturgrenzen zu halten, sondern auch darauf, daß die Sedimentation nicht durch Konvektionsströme gestört wird, die von Temperaturunterschieden herrühren. Die Erfüllung dieser Forderungen wird erschwert durch die an schnell rotierenden Körpern durch Lager- und Gasreibung erzeugte Wärme. Um die Wärmeentwicklung durch Gasreibung möglichst klein zu halten, füllt man den Raum, in dem sich das rotierende System befindet, mit einem unter geringem Druck stehenden Gas möglichst kleiner Zähigkeit und möglichst großer Wärmeleitfähigkeit, vorzugsweise Wasserstoff, oder man evakuiert ihn möglichst vollständig. Der letzte Weg wird weniger gern beschritten, weil die Erzeugung des erforderlichen Hochvakuums mit Umständen verbunden ist und weil man auf diese Weise nicht willkürlich bestimmte Temperaturen einstellen kann. Dies gelingt aber leicht bei Füllung des Rotorraumes mit Wasserstoff von geringem Druck. Dabei stellt sich nach einiger Zeit eine stabile Übertemperatur des Rotors gegenüber den Wandungen des Rotorraumes ein, nämlich diejenige Übertemperatur, bei der durch Wärmeleitung die vom Wasserstoff am Rotor erzeugte Reibungswärme nach den Wänden

Rotierendes System für Beobachtungszentrifugen zur Molekulargewichtsbestimmung

Patentiert im Gebiet der Bundesrepublik Deutschland vom 2. März 1950 an
Patentanmeldung bekanntgemacht am 6. November 1952
Patenterteilung bekanntgemacht am 28. Mai 1953

Die Erfindung betrifft ein rotierendes System für Beobachtungszentrifugen zur Bestimmung von Molekulargewichten. Die der Sedimentation großer Moleküle in starken Zentrifugalfeldern zu analytischen Zwecken zukommende Bedeutung führte zur Entwicklung von Zentrifugen, die mit optischen Mitteln zur Beobachtung der Sedimentation ausgestattet sind. Solche Beobachtungszentrifugen erlauben entweder die Geschwindigkeit der Sedimentation oder die sich nach längerer Einwirkung eines bestimmten Zentrifugalfeldes einstellende Konzentrationsverteilung zu messen; demgemäß unterscheidet man dynamische und statische Meßverfahren.

Bei der üblichen Konstruktion des rotierenden Systems sind die inneren Teile der das Präparat enthaltenden Zelle von einer zylindrischen Zellenhülse umgeben, die in einem bestimmten radialen Abstand parallel zur Drehachse der Zentrifuge angeordnet wird. Zwecks Schleuderung schiebt man die Zellenhülse in eine Bohrung in der Nähe des Umfanges eines scheibenförmigen Rotors aus möglichst festem Werkstoff.

Für wissenschaftliche Zwecke wird ein Trennvermögen verlangt, bei dem die Masse der bisher verwendeten Zellen Zentrifugalkräfte hervorruft, die die Rotoren der bekannten Geräte bis an die Grenze der Festigkeit beansprucht. Dabei sind gelegentliche Rotorbrüche unvermeidlich, was das Arbeiten mit den Geräten gefährlich und kostspielig macht. Was durch Wahl bester Werkstoffe für die hoch beanspruchten Teile gegen diese Gefahren unternommen werden konnte, ist längst geschehen. Fortschritte sind also nur noch durch Verbesserungen der Formgebung denkbar und durch das hier beschriebene rotierende System in der Tat möglich.

Erfindungsgemäß wird die Zentrifugalkraft der Zelle von einem starkwandigen, länglichen, röhren-

Radialrohrzentrifuge

Patentiert im Gebiet der Bundesrepublik Deutschland vom 5. August 1950 an
Patentanmeldung bekanntgemacht am 2. Oktober 1952
Patenterteilung bekanntgemacht am 11. Juni 1953

Die Erfindung betrifft eine Radialrohrzentrifuge. Für präparative Arbeiten mit höchsten Normalbeschleunigungen verwendet man bisher die sogenannten Schrägrohrzentrifugen. Der Läufer dieser Zentrifugen hat äußerlich die Gestalt eines abgestumpften Kreiskegels und wird am äußeren Umfang mit einer größeren Zahl von schrägen Bohrungen ausgestattet. Er rotiert um seine Figurenachse. Die mechanische Festigkeit dieses Läufers erreicht nach praktischen Erfahrungen ein Maximum im Verhältnis zum Fassungsvermögen dann, wenn man eine größere Zahl von Bohrungen, mindestens 8 bis 12 Stück, am Umfang anordnet. Besteht der Wunsch, auf höchste Normalbeschleunigungen zu kommen, so könnte man den Schrägrohrläufer ähnlich verkleinern. Dabei würde man aber zu so kleinen Zellen gelangen, daß die Unterteilung der gesamten Stoffmenge für die praktische Handhabung infolge immer größer werdender prozentualer Stoffverluste nachteilig wird. Auch die Handhabung der vielen kleinen Zellen ist mühsam.

Schließlich müssen bei einer Schrägrohrzentrifuge sehr große Materialmassen des Läufers an der Rotation teilnehmen, die für die Aufnahme der Zentrifugalkräfte des Präparates selbst nicht unmittelbar beitragen und zusätzliche Gefahren für die Umgebung mit sich bringen bzw. kostspieligere Schutzvorrichtungen erfordern.

Demgegenüber kennzeichnet sich die Radialrohrzentrifuge gemäß der Erfindung darin, daß der den Stoff aufnehmende Körper als ein an einem Ende geschlossenes Hohlrohr ausgebildet ist, das, mit seiner Achse senkrecht zur Rotationsachse der Zentrifuge stehend, so in den rotierenden Träger eingeschoben ist, daß es durch die Zentrifugalkräfte

Temperieranlage für Ultrazentrifugen

Patentiert im Gebiet der Bundesrepublik Deutschland vom 7. September 1951 an
Patentanmeldung bekanntgemacht am 6. November 1952
Patenterteilung bekanntgemacht am 11. Juni 1953

Die Erfindung betrifft eine Temperieranlage für Ultrazentrifugen. Eine bei allen bekannten Konstruktionen von Ultrazentrifugen bisher nur mangelhaft gelöste Aufgabe besteht darin, den Läufer während des Betriebes auf einer bestimmten Temperatur zu halten. Grundsätzlich kann dies auf zweierlei Weise erfolgen, und zwar durch das Wärmeträgheitsverfahren oder durch das Übertemperaturverfahren. Das erste besteht darin, die Läuferkammer, das ist der Raum, in dem der Läufer rotiert, so weit wie möglich zu evakuieren, um auf diese Weise alle Gasreibung, aber auch jeden Wärmeaustausch mit der Umgebung bis auf die bei den fraglichen Temperaturen vernachlässigbare Wärmestrahlung, fortzuschaffen. Der Läufer behält bei diesem Verfahren dank seiner Wärmeträgheit die Anfangstemperatur bei. Das zweite Verfahren besteht darin, zwischen dem Läufer und der ihn umgebenden ruhenden Wand eine Gasatmosphäre bestimmter Zusammensetzung und bestimmten Druckes zu schaffen und der umgebenden Wand zwangsläufig eine Temperatur zu erteilen, die so weit unter der Temperatur des Läufers liegt, daß durch Wärmeleitung der Gasatmosphäre gerade so viel Wärme vom Läufer zur umgebenden Wand übertragen wird, wie durch Gasreibung am Läufer entsteht. Der Läufer behält also bei diesem Verfahren seine Temperatur dank des Temperaturunterschiedes gegen die Umgebung, das ist die Übertemperatur, bei.

Die Erfindung betrifft eine nach dem zuletzt genannten Übertemperaturverfahren arbeitende Temperieranlage für Ultrazentrifugen. Gemäß der Erfindung wird die Läuferkammer hinsichtlich der

DEUTSCHES PATENTAMT

AUSLEGESCHRIFT 1 014 348

B 18577 IX/42 l
ANMELDETAG: 8. JANUAR 1952
BEKANNTMACHUNG DER ANMELDUNG UND AUSGABE DER AUSLEGESCHRIFT: 22. AUGUST 1957

1

Die Erfindung betrifft eine Radialrohrzentrifuge. Sie gehört zu der Gruppe von Radialrohrzentrifugen, die mit einer das Präparat aufnehmenden becherförmigen Zelle ausgestattet sind, deren Inneres durch einen Verschlußkörper abgeschlossen werden kann. Diese Zellen stehen senkrecht zur Rotationsachse. In das Innere wird das zu zentrifugierende Präparat eingesetzt.

Es sind Zentrifugenröhrchen bekannt, die an ihrem einen Ende durch ein Verschlußglied verschließbar sind, wobei das zu zentrifugierende Präparat sich in einem Röhrchen vor dem Abschlußglied ansammelt. Weiterhin kennt man Zentrifugenröhrchen, in die ein Einsatzkörper zum Sammeln des zu gewinnenden Präparates eingesetzt ist. Der Einsatz hängt an einem Halter, mit welchem er aus dem Röhrchen herausnehmbar ist. Eine derartige Anordnung gestattet nicht das Verschließen des Röhrchens an dem dem Einsatz entgegengesetzten Ende. Außerdem besteht die Gefahr, daß der Halter für den Einsatz durch die Zentrifugalkräfte bei den hohen Tourenzahlen nach außen gedrückt wird.

Die Erfindung verwendet eine um die Rotationsachse umlaufende, becherförmige Zelle mit einem Verschlußkörper am Boden. Am Boden ist ein herausnehmbarer Einsatz in Form eines Napfes eingebracht, der zur Aufnahme des Sedimentes dient. Der Einsatz trägt auf der Innenseite Rasten als Ansätze für die Enden einer zum Einsetzen und Herausnehmen des Einsatzes dienenden Zange. Das Einsatzstück kann auch zwei Höhlungen tragen, die durch einen axialen kurzen Kanal miteinander verbunden sind. Die dem Boden der Zelle zugekehrte Höhlung des Einsatzstückes kann durch eine aufsetzbare Kappe bzw. eine aufschraubbare Haube besonders abgeschlossen sein.

Es können mehrere napfartig gestaltete Einsatzstücke mit je einem axialen kurzen Kanal im Boden der Zelle in radialer Richtung hintereinander eingesetzt sein, so daß in den einzelnen Einsätzen Sedimente mit verschiedenen Zusammensetzungen sich anreichern können. Die verschiedenen, in radialer Richtung hintereinanderliegenden Einsatzstücke können durch gegenseitiges Verschrauben auch zu einem einzigen Aggregat vereinigt sein. Dann können die Einsätze gemeinsam aus der Zelle herausgenommen werden.

Erfindungsgemäß kann neben einem napfartigen Einsatz zum Sammeln des Sedimentes am Boden der Zelle in einem Abstand von dieser nach der Rotationsachse zu ein weiterer gegensätzlich gerichteter napfartiger Einsatz mit Sammelkammer vorgesehen sein. Von dieser Sammelkammer führt dann ein Gasausgleichskanal zu dem dieses Einsatzstück umgebenden Vorratsraum für das Präparat. Die beiden einander

Radialrohrzentrifuge

Kiel-Wik, Mecklenburger Str. 32/36

Dr.-Ing. Konrad Beyerle, Göttingen,
ist als Erfinder genannt worden

2

gegenüberliegenden Einsatzstücke können durch ein mit Durchbrechungen versehenes Rohrstück miteinander verbunden sein.

Das in Richtung auf die Rotationsachse gelegene Einsatzstück kann auch am inneren Ende des Verschlußkörpers für die Zelle ausgebildet sein. Ferner kann in diesem Einsatzstück ein Ventil vorgesehen werden, welches sich bei der Rotation durch die Zentrifugalkraft selbsttätig öffnet.

Mit den Mitteln der Erfindung kann in der Zelle eine Anreicherung der schweren Korpuskeln an dem am Boden der Zelle angeordneten Einsatz und eine Anreicherung der leichten Korpuskeln an dem in Richtung auf die Rotationsachse gelegenen Einsatzstück erreicht werden. Durch das Herausnehmen der Einsatzstücke mit den durch diese gebildeten Präparatkammern ist die Möglichkeit gegeben, das sedimentierte Präparat nach Beendigung des Rotationsvorganges gut aus der Zelle herauszunehmen, um es weiterhin zu untersuchen.

Unter schweren und leichten Teilchen werden im Rahmen der Erfindung Partikel verstanden, die schwerer bzw. leichter sind als das Lösungsmittel, in welchem sie sich befinden.

Die Verwendung eines am Boden der Zelle eingesetzten Einsatzstückes ergibt den Vorteil eines besonders bequemen Abpipettierens der Präparatlösung. Auch können spezielle präparative Techniken durch die erfinderische Lösung durchgeführt werden.

Die Erfindung ist in mehreren Ausführungsbeispielen in den Zeichnungen jeweils im Längsschnitt durch eine Zelle dargestellt. Es zeigt

Fig. 1 die Anordnung zweier Sedimentsammler für schwere und leichte Korpuskeln,

Fig. 2 das Herausnehmen des äußeren Sedimentsammlers durch eine Zange,

Fig. 3 die Anordnung eines Sedimentsammlers mit einer dahintergeschalteten Sedimentkammer,

COMBINED INTELLIGENCE OBJECTIVES SUBCOMMITTEE
EVALUATION REPORT 318 (13th August 1945)

FRITZ HELLIGE & CO.
FREIBURG - BREISGAU
MANUFACTURERS OF ULTRAZENTRIFUGE

Source: JOLLES, Friedrich Wolfgang (44, non Aryan, never in Party)
Stecklenbergerstr. 34
Thals/Harz
Source was drafted for service with the Wirtschaftsgruppe
Feinmechanik & Optik, working for the civilian sector of the Group.

1. Fritz Hellige & Co., were the makers of an ULTRAZENTRIFUGE (ultra-centrifuge) which was designed to be used in the manufacture of a new explosive ten million times more destructive and powerful than any heretofore known.

2. The raw material used was pitchblende. The end product was a liquid which had to be charged in order to become an explosive.

3. Only a few grams of the liquid had been produced by the spring of this year, which explains why the new explosive was never used against the Allies.

4. In November 1944, the plant, originally located in a suburb of Freiburg/Breisgau, was completely bombed out. According to a Pruefungsbericht which Jolles saw, the plant was evacuated to Kandern, south of Freiburg, where the Ultracentrifuge was set up in a little house about 300 meters from the main factory building.

5. Betriebsleiter FRITZENSCHAFT, who may be located in the suburb of Freiburg where the plant was originally located, or at Kandern, knows everything about the Ultracentrifuge and the new product.

6. Sourve also stated that the new explosive had important peacetime uses, since a quantity about the size of a match box contained enough energy to drive a motor car for twenty years.

7. Source believed that the new explosive was in some way related to the splitting of the atom.

CARDED

E.L. Deuss H.R. Habicht

9th U.S. Army

Figure D.163: CIOS ER 318 [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA—(1943–June 1946)].

[Whereas conventional histories only acknowledge the existence of one wartime uranium gas centrifuge program conducted by Beyerle, Groth, Harteck, and collaborators in the Hamburg/Kiel area, there is evidence demonstrating that additional centrifuge programs existed.

For example, Günter Nagel found German documentation of a previously unknown but apparently quite significant uranium gas centrifuge program that was conducted for at least three or four years under the Army Ordnance Office [Karlsch and Petermann 2007, pp. 249–251]:]

Schumann und Diebner waren sich offenkundig schon früh darüber im Klaren, dass die Isotopentrennung eines der zentralen Probleme des Uranprogramms ist. Deshalb wurden auch Kräfte des II. PI dafür herangezogen. So legten Werner Holtz und Werner Schwietzke Anfang 1942 ein zwei Seiten umfassendes Dokument “Ultrazentrifuge zur Trennung von Gasgemischen (Vorbericht)” vor. [...]

Auf die Beteiligung von Holtz und Schwietzke an der Entwicklung einer Ultrazentrifuge wies auch Dr. Herbert Kunz hin. [...]

Einen weiteren Beleg für die Beteiligung von Holtz und Schwietzke an der Zentrifugenentwicklung lieferte Frau Ursula Schulze, die zu ihrer Flucht 1945 in die “neue Verlagerungsstelle des II. Physikalischen Instituts” im Schloss Zandt bei Cham im Bayerischen Wald berichtete: “Auch Holtz und Schwietzke waren dort angelangt. Dann mussten wir alle schriftlichen Unterlagen der Kernzentrifugenforschung, an der auch Ortwin [Schulze] bei Schwietzke mitgearbeitet hatte, verbrennen. Dabei wussten wir noch nicht, dass Schwietzke Duplikate besaß, was ihn durch unsere Hilfe nach Australien weiterhalf.”

Schumann and Diebner were obviously already aware that isotope separation is one of the central problems of the uranium program. For this reason, resources of the Second Physics Institute were used for this. Thus in early 1942, Werner Holtz and Werner Schwietzke presented a two-page document entitled “Ultracentrifuge for the Separation of Gas Mixtures (Preliminary Report).” [...]

The involvement of Holtz and Schwietzke in the development of an ultracentrifuge was also emphasized by Dr. Ing. Herbert Kunz. [...]

Further evidence of the involvement of Holtz and Schwietzke in centrifuge development was provided by Ms. Ursula Schulze, who reported on her escape in 1945 to the “new relocation office of the Second Physics Institute” in Zandt Castle near Cham in the Bavarian Forest: “Holtz and Schwietzke had arrived there, too, and then we had to burn all the written records of the nuclear centrifuge research, on which also Ortwin [Schulze] had worked with Schwietzke. We did not yet know that Schwietzke possessed duplicates, which helped him in Australia.”

[In the National Archives of Australia, Gernot Eilers found postwar documentation on Werner Schwietzke and his gas centrifuge designs, from the time period during which he emigrated to Australia.]

File on Werner Schwietzke. 1947–1951. National Archives of Australia. Series number MT105/8, control symbol 1/6/3094, barcode 934755. Note: pages are numbered in reverse order in red pencil in upper right corner. https://recordsearch.naa.gov.au/SearchNRetrieve/NAAMedia/ShowImage.aspx?B=934755&T=PDF

[p. 41] Schwietzke was checked closely on his party activities. [...] I enquired from Czerny on his political past and was informed I could be sure he had not dabbled in politics any more than was necessary by his profession. Czerny did not hesitate to say he could vouch for him. This was also the opinion I formed. Schwietzke is the type who is interested in academic not political problems.

As requested I attempted to get details of the laboratory centrifuge.

The position is that due to bombing no existing centrifuge or drawings are available to Dr. Schwietzke. He does however feel he has the capacity to design a similar machine quite easily. [...]

The Centrifuge was made by PHYWE (Trade name of Physicalische Werkstatte) of Göttingen from sketches and instructions. No special drawings, and unlikely that PHYNE have useful data there he feels. [...]

As soon as the centrifuge details submitted by Dr. Schwietzke are received they will be transmitted to Australia.

H. P. Matthews.

[pp. 20–19, the end of a detailed 14-page paper written by Schwietzke in German after the war giving an apparently selective account of his early centrifuge experiments during the war:]

Da die theoretischen Berechnungen der Spannungsverteilung des mit hoher Geschwindigkeit umlaufenden Rotors nur mit einer gewissen Annäherung vorgenommen werden können, war es empfehlenswert, den genau ausgewuchteten Rotor einen Probelauf unterhalb der als kritisch errechneten Umlaufhöchstgeschwindigkeit von 65 000 U/Min. ausführen zu lassen und durch Präzisionsmessungen nach dem Lauf die evt. auftretenden Veränderungen des Rotors genauestens zu bestimmen. Nach einer beträchtlichen Anzahl von Versuchsreihen über mehrere Stunden bei 60 000 U/Min. konnte eine Verformung des Rotors niemals festgestellt werden, so dass eine ständige Betriebsdrehzahl von 56 000 U/Min. bei den vorgesehenen Versuchen ohne Gefahr gewählt werden konnte.	Since the theoretical calculations of the stress distribution of the rotor rotating at high speed can only be carried out with a certain approximation, it was recommended that the precisely balanced rotor be subjected to a test run below the maximum rotational speed of 65,000 rpm, which was calculated as critical, and that any changes in the rotor be precisely determined by precision measurements after the run. After a considerable number of test series over several hours at 60,000 rpm a deformation of the rotor never could be detected, so that a constant operating speed of 56,000 rpm could be selected for the intended tests without danger.
Diese wenig Platz und Aufwand erfordernde Ultrazentrifuge hat sich in der Praxis ausserordentlich gut bewährt.	This ultracentrifuge, which requires little space and effort, has proven itself extraordinarily good in practice.

[Werner Schwietzke and his uranium gas centrifuges clearly existed, as shown by the German and Australian evidence, yet they had been completely forgotten by history. The fact that Werner Grothmann mentioned the importance of Schwietzke and his wartime work [p. 3709] strongly supports both the authenticity and the usefulness of the Werner Grothmann interview transcript.

In contrast, the fact that Erich Schumann neglected to mention Schwietzke and his centrifuges in his postwar writings, even though most of that work was conducted directly under Schumann, suggests that Schumann deliberately omitted major people and programs from his writings to make the wartime German program appear much smaller and much less advanced than it actually was.

German gas centrifuges were produced by:

- Anschütz in Kiel (pp. 3494–3515), which had decades of experience making advanced gyroscopes (p. 1500).
- PHYWE (Physicalische Werkstatte) in Göttingen (p. 3543), which also made extremely advanced liquid centrifuges for biochemical research (pp. 2397–2399).
- Linde Eismaschinen in Munich (pp. 3498–3507), which had decades of experience with gas handling and rotating compressor machinery.
- Hellige in Freiburg (pp. 3512–3540).
- Hellige in Breslau/Wrocław (p. 4522).
- One or more factories in Switzerland for export to Germany (pp. 3545–3548). This was reported by Constantin Chilowsky (Russian/French/Swiss, 1880–1958), a distinguished scientist with decades of experience working on sonar and a wide variety of other technologies, who said he had personally seen the factory and the uranium centrifuges.
- Quite possibly other locations as well.

How many uranium gas centrifuges were produced by or for Germany during the war? At what sites were they installed and operated? How much enriched uranium did they produce in total, and how highly enriched was it? Can files that would answer these questions be located in various national archives and declassified?

Centrifugation proved so superior to the U.S. Manhattan Project's enrichment methods that the German gas centrifuge designs are now the worldwide standard for uranium enrichment. The evidence clearly demonstrates that the technology was developed and demonstrated over the course of the war by German scientists and engineers, and spread by German scientists and engineers (as well as the prototypes and documentation they had produced) to other countries after the war. The Soviet Union was one of those countries to which the technology spread (via scientists such as Max Steenbeck and Gernot Zippe), but not the origin of the technology [Helmbold 2016; Kemp 2009, 2012, 2017; NYT 2004-03-23].

Just as most of these German centrifuge programs were kept so quiet during World War II and in all the decades afterward, it is entirely possible that other major wartime programs on advanced nuclear or other technologies are still unknown or poorly understood.]

H. T. Wensel to Robert Furman. 14 March 1944. See document photos on pp. 3546–3548. [NARA RG 227, Microfilm M1392, Bush-Conant File Relating to the Development of the Atomic Bomb, https://downloads.paperlessarchives.com, pp. 6084–6089.]

March 14, 1944

MEMORANDUM

TO: Major R. R. Furman

FROM: H. T. Wensel

This memorandum will put on record the information which I gave you orally yesterday.

Dr. H. C. Urey of Columbia University was approached through a Professor Perrin, who was then an exchange Professor in the Chemistry Department at Columbia University, on behalf of one Constantin Chilowsky. Chilowsky was desirous of selling an invention, the exact method never disclosed to us, for accomplishing the same purpose which the Manhattan District is seeking to. Professor Urey indicated that he was not interested in the matter but passed the information on to the OSRD, and I was asked to interview Chilowsky by Dr. Conant to see what I could find out. I used my credentials as a member of the National Bureau of Standards and indicated to Chilowsky and Professor Perrin that I had no other government connection.

Chilowsky was a Swiss and refused to divulge even the approximate nature of his method but, inasmuch as I indicated that the government would be apathetic to the idea until shown that something practical was involved, in order to "sell" me on the importance of the job, he indicated to me that the Germans were actively engaged on the same objective. In particular, he told me he had personally seen in a factory in Switzerland centrifuges which were being produced to be sent to Germany for the Germans' work on this field.

Chilowsky also told me that he had a moral and financial obligation to offer first crack at his invention to the British group of Halban. It seems that Halban and his group had some part in developing the invention in question. Halban is at present with the British team in Montreal, and it may be that Chilowsky's whereabouts can be traced through Halban if no other means of approach is available.

[A Swiss factory was producing uranium centrifuges and sending them to Germany, apparently in 1942 or 1943; details are still classified.

Constantin Chilowsky (Russian/French/Swiss, 1880–1958) was a distinguished scientist with decades of experience working on a wide variety of technologies ranging from sonar to fission reactors:

> Constantin Chilowsky [obituary]. *New York Daily News*, 1 July 1958, p. 386.
> https://www.newspapers.com/article/daily-news-death-of-constantin-chilowsky/114034053/
>
> *Technology Mobilization: Hearings Before a Subcommittee of the Committee on Military Affairs. United States Senate.* 1942. December 12, 14, 17-19. Washington, DC: U.S. Government Printing Office. p. 631: Constantin Chilowsky.
> https://books.google.com/books?id=LzoTAAAAIAAJ&pg=PA631

Thus Chilowsky was a thoroughly qualified and highly reputable source, and he said that he had personally seen the factory and the uranium centrifuges. His story was considered credible and important by French nuclear physicist Francis Perrin and Manhattan Project scientists Harold C. Urey and H. T. Wensel.]

Gas Centrifuge

June 9, 1965

[redacted]

Der Spiegel

A fence as high as a man in the Stetternich Forest near Julich hides Bonn's most recent monument to scientific political initiative: the federally owned Company for Nuclear Process Engineering (GKT)

Four research buildings and barracks equipped with modern instruments and built with almost 3 million Marks of taxpayers money, idly await their users:

> Instead of the expected 35 scientists and engineers so far only 4 have moved into the buildings over the newly built access road.
>
> Of 19 technicians transferred to Julich at the end of 1964 by the Frankfurt metallurgic enterprise, Degussa, 16 have in the meantime deserted.

Thus the first and up to now only West German attempt to combine atomic scientific development groups at one location, as per the American example, is threatened with failure.

In the USA the usefulness of such combined effort has proved itself because the concentration of scientists with its attendant continuous exchange of experimental results avoided expensive parallel development and thereby also accelerated the research.

Granted in West Germany another motive led to the Julich co-op plan. One of the gas centrifuges developed by Bonn's Professor Wilhelm Groth was declared a state secret at the behest of Washington. With this centrifuge it is possible to separate the highly radioactive uranium 235, which is contained in natural uranium metal only to an extent of 0.714% from the isotopes 234 and 238 and thereby obtain the intensive radiation needed for commercially useful nuclear fuel. (sic!)

But while the scientific officials and the professorial nuclear researcher Groth thought only of the cheap nuclear power of the future, the Americans suspected something terrible. They feared that this knowledge of the German researchers, which is just as useful in making atom bombs - spread out in many locations, its security classification poorly protected - would

-2-

lead to an undesired enlargement of the Atomic Club (USA, Great Britain, France, USSR, and Red China). Washington therefore welcomed the 3 million project in Julich.

On top of this the Americans asked the federal government to withhold many of the results of the Groth experiment from the European Atomic Community (Euratom). Otherwise - according to Washington - the tempo of General de Gaulle's nuclear arming could be undesirably accelerated. (sic!)

Professor Groth found it flattering to have his centrifuge declared the first scientific state secret of West Germany. Since security measures could not be guaranteed at the Bonn University, even he promoted the construction of a nuclear process research center to which all associates could be called who were experimenting either in isotope separation or related processes.

After nuclear professor Hans Martin from Kiel, Diploma Engineer Dr. Beyerle from Aachen, and Scientist Zippe from the Frankfurt Degussa company all indicated their willingness to join in the task the federal government approved the construction.

But before the centrifugal forces in Julich could be mobilized to separate isotopes, they were applied to the organization itself.

> It took the Science Ministry 3½ years, until the Fall of 1964, to set up the Company for Nuclear Process Engineering as a federal corporation, because the Finance Minister opposed to setting up any new federal enterprises.
>
> Professor Martin from Kiel indicated that he would only decide how many of his people he would release to Julich during 1965.
>
> Of the 19 Degussa technicians 16 returned to Frankfurt because they could only obtain short term leases to house their families.
>
> Professor Groth recently surprised the Federal constructors with the statement that since security measures in his Bonn Institute had proved sufficient, the move to Julich was no longer necessary.

The responsible official of Bonn's Scientific Ministry, Ministerial Advisor Haase, feels he has been betrayed by Groth. Despite the fact that he was satisfied with the security measures

-3-

at the University "very early", he (Groth) silently let the construction work continue. According to Haase he even demanded, as late as the middle of last year, that a roomy front office for himself plus seven rooms for his staff be included in the plans.

Binding contracts, with which the Scientific Ministerial-Advisor could still set the independently-minded Professors into motion toward Julich, don't exist.

Diploma Engineer Beyerle, who, as scientific supplier to the Groth group, now too will remain where he is in Aachen, opines that, "People in government often start things from the rear and then afterwards wonder why the front end doesn't fit."

Figure D.168: Samuel Goudsmit's personal copy of an English translation of *Der Spiegel*, 8 June 1965, Kernforschung von hinten [NARA RG GOUDS, Entry UD-7420, Box 8, Folder Haycock/Brown/Tape AEC; https://www.spiegel.de/politik/von-hinten-a-359489f2-0002-0001-0000-000046272934]. R. Scott Kemp. 2009. Gas Centrifuge Theory and Development: A Review of U.S. Programs. ***Science and Global Security*** **17:1–19.**

When the Manhattan Project began, centrifuges of this kind were considered as a candidate technology for concentrating uranium-235 for the first nuclear weapon. [Jesse] Beams was asked to oversee the centrifuge project and led a design team at the University of Virginia. The Westinghouse Research Laboratory was charged with building the first production machines, and testing was done at the Standard Oil Development Company in Bayway, New Jersey. The team at the University of Virginia designed a supercritical machine, 7.35 in diameter and 136 in long, which operated at 270 m/s in a four-stream mode. Westinghouse built a slightly smaller version, 7.2 in diameter by 132 in long, as well as a subcritical machine, 7.2 in diameter by 42 in long. Separation tests began with the subcritical unit in August 1943 and continued for 93 of 99 days before the oil gland developed a leak and caused the centrifuge to crash at 215 m/s in December of 1943. The program was terminated by enrichment-project manager Harold Urey a few weeks later in favor of gaseous diffusion. [...]

In December 1951, the Committee on Isotope Separation of the Division of Research strongly advised against a post-war centrifuge revival, noting that centrifuges could not compete economically with existing gaseous diffusion technology. That would change in 1953 when German groups led by Wilhelm Groth and Konrad Beyerle, and a Dutch group led by Jacob Kistemaker, began asserting that their centrifuges would soon be more economical than American-style diffusion. Fearing a loss of their uranium-enrichment monopoly, the U.S. Atomic Energy Commission decided to revive centrifuge research in September 1954. But the revival was desultory: No machines were built because the AEC was confident that it would have full access to German technology, which was at that time the most advanced in the West. [...]

In the summer of 1956, the Soviet Union began repatriating captive German scientists who had been working on uranium enrichment at Institutes A and G at Sukhumi on the Black Sea. Oswald Francis ("Mike") Schuette of the U.S. Office of Naval Intelligence had the task of interrogating the returning Germans. By chance, one of his subjects was the Austrian scientist Gernot Zippe, who wound up in Germany only because he could not afford rail fare back to his native Austria. Zippe had become a flight instructor for the Luftwaffe after he finished his Ph.D. He was captured by Soviet forces and sent to the Krasnogorsk detention camp, but when the Soviets learned of his technical background he was transferred to Institute A, where he was put in charge of mechanical developments for the Soviet centrifuge program.

Schutte's report of Zippe's activities attracted the interest of the Intelligence Division of the U.S. Atomic Energy Commission. They arranged to bring Zippe to the United States in 1957 under a false passport and the assumed name of "Dr. Schubert." AEC scientists and intelligence officials interrogated Zippe in an all-day session at the Shoreham Hotel in Washington, D.C. This was followed by a more collegial debriefing several days later at the University of Virginia. Zippe revealed that he and the Soviets had worked out a completely novel design that did away with the thrust bearings and oil glands that had been so problematic in the U.S. centrifuge. The AEC arranged to have Zippe return to the United States on contract to the University of Virginia, where he would replicate the Soviet machine in exchange for a $10,000 salary. In August 1958, Zippe returned to Virginia, and less than a year later he produced a working replica of the Soviet machine.

Karl Cohen, whose theoretical contributions appear later in this article, was asked to assess Zippe's work for the Atomic Energy Commission. He was so impressed that he advised the commission to expand its centrifuge efforts in the direction of the Soviet design. By April 1960 the Division of Research approved a program to be housed at the Oak Ridge Gaseous Diffusion Plant under the management of Union Carbide Corporation, Nuclear Division. Work was begun 1 November 1960, and included the construction of a cascade based on the Soviet design, as well as improvements to centrifuge theory, and a continuation of the study on novel materials. [...]

In the late 1970s, the U.S. Department of Energy predicted that the demand for nuclear power, and thus enriched uranium, would grow dramatically in the coming decade. Saddled with only aging gaseous-diffusion plants, the DOE proposed a commercial-scale centrifuge facility to meet future enrichment demand. In 1977, Congress authorized an 8.8 million SWU/yr plant at Portsmouth, Ohio. The first stages of the plant were based on Set III centrifuges, 24 in diameter, 40 feet long, at 200 SWU/yr per machine. In time, however, it became apparent that the demand for enriched uranium had not increased as predicted; competing lifetime-extension programs on sunk-cost gaseous diffusion plants obviated the need for a new plant; and claims of economic mismanagement plagued the centrifuge program. The entire centrifuge effort was cancelled on June 5, 1985. Only 3000 machines had been installed at the Portsmouth facility at a total cost of $2.6 billion.

Despite War, Paying Russia For Uranium. ***New York Times.*** **15 June 2023, p. A1.**

The United States' reliance on nuclear power is primed to grow as the country aims to decrease reliance on fossil fuels. But no American-owned company enriches uranium. The United States once dominated the market, until a swirl of historical factors, including an enriched-uranium-buying deal between Russia and the United States designed to promote Russia's peaceful nuclear program after the Soviet Union's collapse, enabled Russia to corner half the global market. The United States ceased enriching uranium entirely. [...]

Roughly a third of enriched uranium used in the United States is now imported from Russia, the world's cheapest producer [8]. Most of the rest is imported from Europe [9]. A final, smaller portion is produced by a British-Dutch-German consortium operating in the United States [10]. [...]

In the 1950s, as the nuclear era began in earnest, Piketon became the site of one of two enormous enrichment facilities in the Ohio River Valley region, where a process called gaseous diffusion was used.

Meanwhile, the Soviet Union developed centrifuges in a secret program, relying on a team of German physicists and engineers captured toward the end of World War II. Its centrifuges proved to be 20 times as energy efficient as gaseous diffusion. By the end of the Cold War, the United States and Russia had roughly equal enrichment capacities, but huge differences in the cost of production.

In 1993, Washington and Moscow signed an agreement, dubbed Megatons to Megawatts, in which the United States purchased and imported much of Russia's enormous glut of weapons-grade uranium, which it then downgraded to use in power plants. This provided the U.S. with cheap fuel and Moscow with cash, and was seen as a de-escalatory gesture.

But it also destroyed the profitability of America's inefficient enrichment facilities, which were eventually shuttered. Then, instead of investing in upgraded centrifuges in the United States, successive administrations kept buying from Russia.

D.4.3 Uranium-235 Enrichment via Electromagnetic Separation

[German reports captured by the U.S. Alsos Mission also show that there was extensive work throughout the war on electromagnetic systems for uranium enrichment (similar to the U.S. calutrons at Oak Ridge). That work was conducted by physicists and engineers such as Manfred von Ardenne, Heinz Ewald, Richard Herzog, Hans Kopfermann, and Wilhelm Walcher. Unless otherwise noted, text for G-series captured German nuclear reports cited here consists of the English-language abstracts prepared by American scientists who studied the German reports.]

G-375. Richard Herzog. Report on the Status of the Work Towards Construction of a Large New Mass Spectrometer. 1943. Vienna.

Construction principles are outlined as they were patented in 1943 and details of the design are described. The manifold ways of focusing (direction focusing in both planes, energy focusing over great regions, radiation focusing of the ion source and the acceleration field) assure great intensity of the mass spectrometer even with great resolution, such intensities as are needed for separation of isotopes. The instrument will enable scientists to detect and determine smallest quantities of elements produced by nuclear reactions and relative abundance of isotopes.

G-256. Mass Spectrograph Construction Planned by the German Post Office Department Research Institution. [Über den Aufbau eines Massenspektrographen bei der Forschungsanstalt der Deutschen Reichspost.] 1944.

Construction is planned of a mass spectrograph equipped with a single lens and with the electric field installed between the pole faces of the magnets. With improved lens correction a very high resolving power is provided and high intensity of beam if the diaphragm is wide open. The instrument is planned to serve as a precision tool for determination of mass defects when the spectrometer slit is narrowed or for isotope separation when the slit is widened. The mass scale is planned to be M/M–8%. Magnet and magnet corrections needed are described in detail.

G-196. Wilhelm Walcher. Report on the Status of Mass Spectroscope Work at Kiel. The Effect of Space Charge on Focussing Properties of Magnetic Sector Fields. 1942.

Mass spectrograph built in Kiel to separate U isotopes. On the basis of tests made with Ag, can expect daily separation of from 2 to 6×10^{-8} moles of U^{235}. Mathematical determination of the effect of electrostatic repulsion of the particles on the cross section of an ion beam.

G-291. Wilhelm Walcher. Report on Investigations of Ion Sources for High Power Installations. 12 October 1944.

Requirements for an ion source best suited for use with high power installations are postulated and a table is given that compares capacity and current characteristics of 8 known ion sources. Experiments are described investigating electron-optical beam characteristics of the pendulum ion source of Heil and of a magnetron ion source, the resulting characteristics of the ion currents are illustrated.

Wilhelm Walcher. 1943. Über die Verwendungsmöglichkeiten von Glühanoden zur massenspektroskopischen Isotopentrennung. [About the Possible uses of Anodes for Mass Spectroscopic Isotope Separation.] *Zeitschrift für Physik* 121:604–613.

Aus der Kenntnis des Emissionsvorganges der Kunsman-Koch-Anode wird geschlossen, daß Elemente mit einer Ionisierungsarbeit, die kleiner als die Austrittsarbeit der Trägersubstanz (Wolfram mit adsorbiertem Sauerstoff, maximal etwa 9 eV) ist, in einer solchen Anode in Ionenform erzeugt werden können. Es zeigt sich jedoch, daß diese Möglichkeit außer bei den Alkalien nur bei der In-, Ga-, Tl-Gruppe besteht, während z. B. die Erdalkalien für eine Ionisierung nach dieser Methode ungeeignet sind. Gründe hierfür werden angegeben. — Die Ausbeute der Alkalianoden wird zu fast 100% des auf der inneren Oberfläche des W-Pulvers adsorbierten Alkalimetalls gefunden, und zwar ist die in Amperestunden gemessene Kapazität konstant und weitgehend unabhängig vom Emissionsstrom, der bei einer Rubidiumanode bis zu 0,7 mA/cm^2 dauernd gesteigert werden kann. Die Ausbeute einer Indiumanode hingegen beträgt nur etwa 5%. — Es wird gezeigt, daß sich die Anoden regenerieren lassen.

From the knowledge of the emission process of the Kunsman-Koch anode it is concluded that elements with an ionization energy which is smaller than the output energy of the carrier substance (tungsten with adsorbed oxygen, maximum about 9 eV) can be produced in such an anode in ion form. However, it has been shown that this possibility exists only for the in-, Ga-, Tl-group except for the alkalis, whereas the alkaline earths are unsuitable for ionization according to this method. Reasons for this are given.—The yield of the alkali anodes is found to almost 100% of the alkali metal adsorbed on the inner surface of the W powder, namely the capacity measured in ampere hours is constant and largely independent of the emission current, which can be continuously increased up to 0.7 mA/cm^2 with a rubidium anode. The yield of an indium anode on the other hand is only about 5%.—It is shown that the anodes can be regenerated.

Wilhelm Walcher. 1943. Der Einfluß der Raumladung auf die Abbildungseigenschaften magnetischer Sektorfelder. [The Influence of Space Charge on the Resolving Power of Sector-Shaped Magnetic Fields.] *Zeitschrift für Physik* 121:719–728.

Es wird gezeigt, daß ein Bündel geladener Teilchen, das auf eine Brennlinie zielt, trotz des abstoßenden Einflusses der Raumladung in einer anderen Brennlinie fokussiert werden kann. Die Fokussierungsbedingungen werden für den feldfreien Raum und für magnetische Sektorfelder angegeben, die Erweiterung der Theorie auf allgemeine Sektorfelder an einem Beispiel besprochen. Folgerungen für den Bau von Massenspektrographen, insbesondere solchen für Isotopentrennung, werden gezogen.

It is shown that a bundle of charged particles aiming at a focal line can be focused in another focal line despite the repulsive influence of space charge. The focusing conditions are given for the field-free space and for magnetic sector fields, the extension of the theory to general sector fields is discussed with an example. Conclusions for the construction of mass spectrographs, especially those for isotope separation, are drawn.

BIOS 1487. *Chemical Laboratory Instrumentation in Germany.* pp. 5–15.

The estimation of stable isotopes for most of the research teams in Germany using them was done on a mass spectrometer designed and made by Dr. W. Paul of the Second Physics Institute Göttingen. A second similar instrument was made at Göttingen for Professor Heisenberg's Institute but was only completed late in the War and was not much used. [...]

The results given by Dr. Paul in his description of the instrument (loc. cit) showed that its resolution was just sufficient to bring the deflection to zero between the two thallium isotopes of mass 203 and 205, whilst its sensitivity could be made sufficient to demonstrate the existence of the radio active potassium isotope K^{40} which is present in the proportion of 0.012%[...] The results of measurements of the relative concentration of the isotopes of rubidium, thallium, potassium, neon, silver and nitrogen are given showing an accuracy of 1% or better.

The instrument was operated by Dr. Paul during our visit. It was clear from this demonstration that the resolving power was as good as was claimed—the isotopes of mercury masses 198–202, from the diffusion pump used to evacuate the apparatus, being shown readily, whilst the sensitivity was ample to show the presence of the rare neon isotope.

[...] It is the more remarkable that apparently most of the workers in Germany doing work with stable isotopes during the War, relied on this instrument for their analyses.

1994. Obituaries: Wolfgang Paul. *Physics Today* 47:7:76. [https://pubs.aip.org/physicstoday/article/47/7/76/407994/Wolfgang-Paul]

[...] After two years with the Technische Hochschule Munich, he went in 1934 to the Technische Hochschule Berlin, where he joined Hans Kopfermann's research group and earned the diploma (1937) and doctorate (1939) degrees. In 1937 he moved with that team and set out to participate in pioneering studies at the universities of Kiel and later Göttingen on the hyperfine structure of atomic spectra and—with Wilhelm Walcher—on mass spectrometry. In 1944 he became a faculty member at Göttingen, where he worked with the legendary 6-MeV betatron, the first of its kind on the European continent.

[Wolfgang Paul (German, 1913–1993) won a Nobel Prize in Physics in 1989 for his experimental physics work on the electromagnetic manipulation and trapping of ions, of which the invention described in BIOS 1487 was just one example. Wolfgang Paul should not be confused with Wolfgang Pauli (Austrian, 1900–1958), who won a Nobel Prize in Physics in 1945 for his work on theoretical physics.

Paul's mass spectrometer from BIOS 1487 (or similar instruments) would have been ideal for monitoring the progress of uranium isotope enrichment by providing a rapid and reliable analysis of the uranium isotope ratios at various points in the enrichment process. If the instrument could readily separate isotopes of thallium or mercury with slightly different masses around 200, it could distinguish between uranium isotopes of masses 235 and 238.

Please see figures of Paul's mass spectrometer from BIOS 1487 on the following pages.

In fact, if this design were scaled up, given some modifications, and mass-produced, those mass-produced versions could have been used like calutrons to actually enrich significant amounts of weapons-grade uranium.

From publicly available references, it is unclear just how much nuclear-weapons-related work Wolfgang Paul may have done during the war.]

G-139. Heinz Ewald. Eine neue Methode zur Magnetischen Isotopentrennung. [A New Method of Magnetic Isotope Separation.] 3 March 1942.

Reviews use of mass spectrograph to separate isotopes. Limitations of methods used heretofore. Principle of new separation method. Ions of homogeneous energy enter slit B' at angle E into homogeneous magnetic field with limits *bb*, *cc*. Field strength is so regulated that the heavy masses M_2 just leave the magnetic whereas the light masses M_1 cannot quite leave the magnetic field and are bent back toward *b*. Various applications of this principle are illustrated and discussed: (1) Annular magnetic field with ion source in the center. (2) Linear arrangement with rectangular magnetic field. (3) Annular magnetic field with ion source on the outside and target for heavy particles in the center. Calculations are included to demonstrate practicability of this method.

[See pp. 3563–3570. Ewald's design is closely related to Manfred von Ardenne's design below, and both were apparently part of the same project.]

Manfred von Ardenne. Über eine neuen magnetischen Isotopentrenner für hohen Massentransport. April 1942. [From Moscow archive, courtesy of Rainer Karlsch]

[See pp. 3571–3592. In this report, Manfred von Ardenne gave a detailed design for the electromagnetic isotope separator concept that was described in Ewald's report. In particular, he showed how to use a large number of ion beams with only one set of magnets, thereby greatly increasing the production rate of U-235. Von Ardenne's report even included a photograph of a prototype that he had built for experiments (p. 3590).]

Samuel A. Goudsmit. 16 June 1945. SUBJECT: Baron von Ardenne's Isotope Separation. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA—(1943–June 1946)]

1. Among the Reichsforschungsrat papers, we have found the research report of the work which von Ardenne did for the Reichspost. The report is dated April 1942 and describes a magnetic isotope separator in detail. It was sent to the RFR by Esau.

2. Attached is also an interesting commentary by von Ardenne himself. In this, he states that isotope separation is essential to decrease the amount of uranium necessary for the uranium machine. He claims that indications regarding developments, especially in the U.S.A., which aim at a decrease of the uranium quantity in the U-machine, have recently seeped through. Further down, he claims that the method invented by him is new and that, by keeping the development work very secret, an important advantage can be gained over the high level of experimental nuclear physics in the U.S.A.

[For much more information on Manfred von Ardenne's calutron-like electromagnetic isotope separators, see the following pages, as well as pp. 4183–4184.]

Eine neue Methode zur magnetischen Isotopentrennung.

ET. 22003

von Heinz Ewald.

This document has been declassified by author y of issuing installation. Le... dated 4/4/5? Noted by ...

I. Die bisherige Entwicklung der massenspektrographischen Isotopentrennung.

Massenspektrographen sind ihrer ersten Bestimmung nach für die genaue Messung von Isotopengewichten und von relativen Häufigkeiten gebaut worden und hierfür im Verlaufe der nun zwei Jahrzehnte dauernden Entwicklung zu hoher Vollkommenheit gebracht.

Der Gedanke ihrer Verwendung für das Problem der Trennung von Isotopen in wägbaren Mengen ist sehr naheliegend und in einer ganzen Reihe von Arbeiten praktisch erprobt. So ist versucht worden, die bekannten Spektrographentypen mit geringen zweckentsprechenden Abänderungen hierfür zu verwenden. Wegen des geringen Massentransportes in diesen Apparaten konnten jedoch von vornherein auf diesem Wege nur sehr geringe Gewichtsmengen getrennter Isotope erhofft werden. Praktisch sind dann auch nicht mehr als einige $1o^{-5}$g erzielt worden.1)

Die Gründe für diese Begrenzung der Ausbeute sind prinzipieller Natur. Die Schwierigkeiten sind kurz folgende :

---

1) (a) M. Morand, Ann. de physiqué(1o) 7, 1o3, 1927.($1o^{-5}$g Li)
   (b) K.P.Jakowlew, Z. Phys. 64, 378, 193o (Ne-Trennung in einer Aston-Apparatur, $1o^{-7}$–$1o^{-6}$g).
   (c) M.L.Oliphant, E.S.Shire, B.M.Crowther, Proc.Roy.Soc. Lond. 146, 922, 1934.(Li^6 und Li^7, Grössenordnung $1o^{-7}$g).
   (d) E.L.Yates, Proc.Roy.Soc.Lond.,168, 148, 1938. ($3\cdot1o^{-5}$g Li^7, $2\cdot1o^{-6}$g B^{10}und B^{11} und einige $1o^{-6}$g C^{12}).
   (e) A.O.Nier, E.T.Booth, J.R.Dunning, A.V.Grosse, Phys. Rev. 57, 546, 194o.(Einige $1o^{-7}$g U^{238}).
   (f) Dieselben, Phys. Rev. 57, 748, 194o ($4\cdot1o^{-6}$g U^{238}).
   (g) K.H.Kingdon, H.C.Pollock, E.T.Booth, J.R.Dunning, Phys. Rev. 57, 749, 194o,($1,8\cdot1o^{-6}$g U^{238}).

Allen üblichen Massenspektrographen gemeinsam ist die Verwendung eines eng gebündelten Ionenstrahles, der nach Durchtritt durch einen relativ engen Eintrittsspalt durch eine im Einzelfall verschiedene Feldanordnung in ein "Massenspektrum" zerlegt wird. Das zur Trennung benachbarter Masseneinheiten notwendige Auflösungsvermögen verbietet es, dass die Breite des Eintrittspaltes grössenordnungsmässig Millimeter übersteigt. Hieraus folgt von vornherein eine sehr unerwünschte Begrenzung des Ionenstromes.

Bei dem Versuch, die Stromdichte und damit den Massentransport in dem notwendigerweise so engen Ionenbündel möglichst gross zu machen, steht man bald an praktischen Grenzen. Die Ionen emittierende Zone der Quelle kann bei den üblichen Spektrographen nicht wesentlich grösser als die Fläche des Eintrittsspaltes sein. Die starke Raumladung in der Ionenquelle selber, also dort wo die Ionen ihre relativ geringste Geschwindigkeit haben und am längsten verweilen, hindert eine entsprechende Steigerung der Emissionsdichte der Quelle. Als weitere Folge der auftretenden Raumladungen macht sich bei steigender Stromdichte die elektrostatische Abstossung der Ionen im Strahlengang in zunehmendem Masse störend bemerkbar. Dadurch kann die Fokussierung bzw. die Auflösung so verschlechtert werden, dass eine hinreichende Trennung nicht mehr gelingt.

In der Erkenntnis, dass die Raumladungen in erster Linie die Ausbeuten begrenzen, suchte man nach Anordnungen, die einmal die Verwendung ausgedehnterer Ionenquellen gestatten und weiter auf die bisherige enge Bündelung der Ionen im Strahlengang verzichten können. Dieses Ziel verfolgten die Arbeiten von Smythe-Rumbaugh-West u.a. und von Walcher 1) zum Teil mit recht gutem Erfolg.

---

1) (a) W.R.Smythe, L.H.Rumbaugh, S.S.West, Phys.Rev.45, 724, 1934 ($1o^{-3}$g K^{39} und $1o^{-6}$g Li).
   (b) L.H.Rumbaugh, Phys.Rev. 49, 882, 1936.
   (c) L.H.Rumbaugh, L.R.Hafstad, Phys.Rev.5o, 681, 1936. ($2\cdot1o^{-5}$g Li^6 und $2\cdot1o^{-4}$g Li^7).
   (d) W.R.Smythe, A.Hemmendinger, Phys.Rev.51, 146, 178, 1937 ($1,7\cdot1o^{-4}$g K^{39}/h).
   (e) A.Hemmendinger, W.R.Smythe, Phys.Rev.51, 1o52, 1937. ($2\cdot1o^{-3}$g Rb^{85})
   (f) W.Walcher, Z.Phys.1o8, 376, 1938 ($6\cdot1o^{-6}$g/h Rb^{85} und $2.1o^{-6}$g/h Rb^{87}).

Ein wesentliches Kennzeichen dieser Arbeiten ist, dass man bei ihnen mit parallelen Ionenstrahlen arbeitet, die von bereits relativ ausgedehnten Ionenquellen ausgehen. Für diesen Sonderfall können Feldanordnungen angegeben werden, bei denen sich trotz ausgedehnter Ionenquelle eine Fokussierung und gerade genügende Auflösung in ein Massenspektrum erreichen lassen. Als Mass für die Ausdehnung einer Ionenquelle soll die Grösse der Ionen emittierenden Fläche angesehen werden.

In den Arbeiten der Amerikaner wird eine lange spaltförmige Ionenquelle in neuer Anordnung verwendet. Der Spalt von einigen 2o cm Länge und auch einigen Millimetern Breite kann bei einer solchen Ausdehnung unter Berücksichtigung der Grösse des notwendigen Trennmagneten nur noch parallel zum Polschuhspalt des Magneten angeordnet sein und nicht mehr senkrecht. Durch eine besondere Formgebung der Polschuhe hat es sich ermöglichen lassen, dass die parallelen Ionenstrahlen trotz der Ausdehnung der Quelle zu einem Massenspektrum fokussiert werden. Statt des bisher nötigen, eng gebündelten Ionenstrahles ist dort eine Möglichkeit gefunden, einen ebenen, flächenhaft verteilten Ionenstrahl grösserer Ausdehnung zu verwenden.

Bei diesen Arbeiten wurde der praktisch erreichbare Massentransport zwar um mehrere Zehnerpotenzen gesteigert, blieb aber doch in der Grössenordnung von Milligrammen. Die Gründe sind wieder in einer Raumladungsbegrenzung der Ionenausbeute und des Auflösungsvermögens zu suchen.

II. Prinzip einer neuen magnetischen Isotopentrennung.

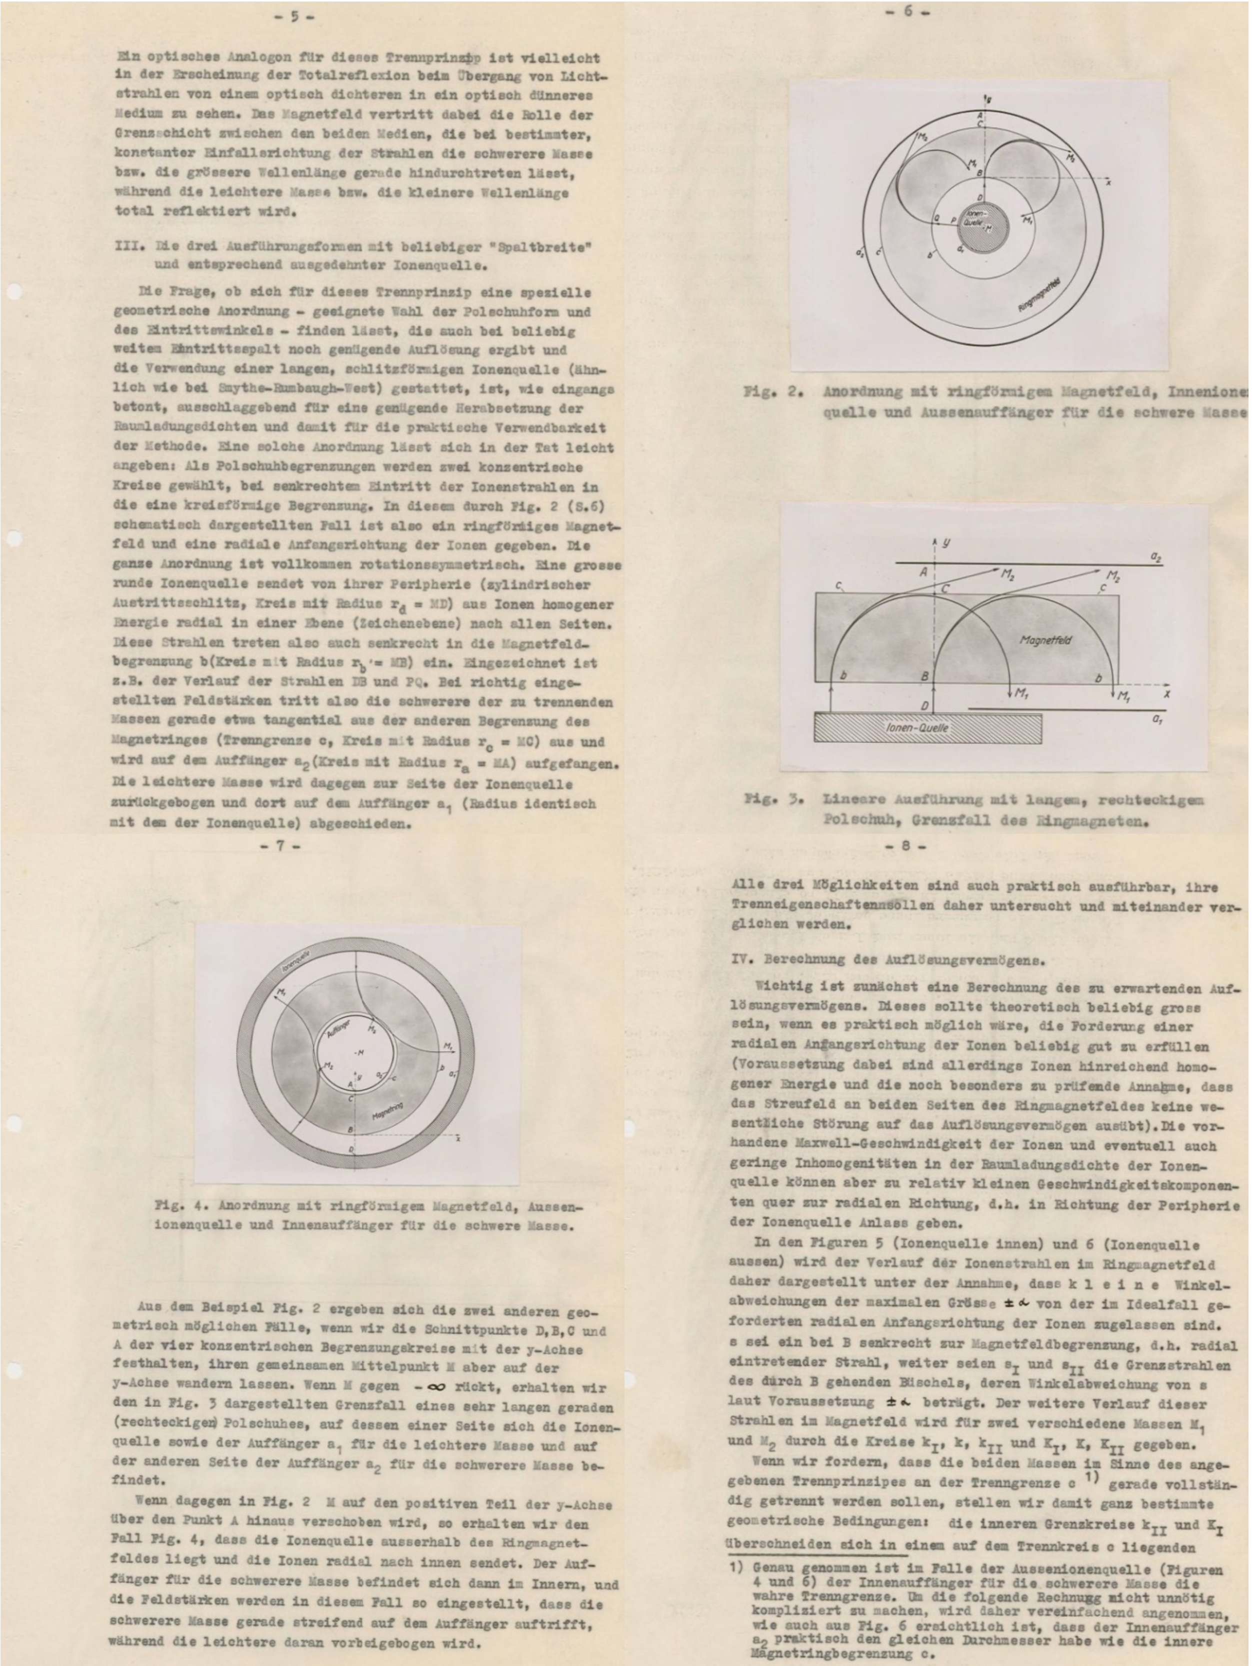
Die vorliegende Arbeit dient der Beschreibung eines neuartigen magnetischen Apparates zur Isotopentrennung, der durch die Besonderheit und Einfachheit seiner geometrischen Anordnung wesentlich von den bisherigen Ausführungen abweicht.

Für das Problem der Trennung zweier Isotope oder zweier Gruppen von leichteren und schwereren Isotopen kann man auf eine Zerlegung des Ionenstrahles in ein Massenspektrum und auch auf eine Fokussierung im üblichen Sinne verzichten, wenn man die in Fig. 1 dargestellte einfache Trennmöglichkeit verwendet. Ionen homogener Energie treten unter einer vorgegebenen Richtung ε durch einen Spalt B' in ein homogenes Magnetfeld mit den Begrenzungen bb und cc ein; die Kraftlinien dieses Magnetfeldes verlaufen senkrecht zur Zeichenebene . Die Feldstärke wird so einreguliert, dass die schwerere der zu trennenden Massen, M_2, das Magnetfeld auf der anderen Seite, an der Trenngrenze c, gerade etwa streifend verlässt, während die leichtere Masse M_1 gerade nicht austreten kann und zur Eintrittsbegrenzung b zurückgebogen wird. Die so getrennten Massen M_1 und M_2 werden dann auf den Auffängern a_1 und a_2 aufgefangen.

Fig. 1. Prinzip der Trennung.

Eine solche Anordnung hat gegenüber den bisherigen Massenspektrographen folgende Besonderheit: die Massendispersion am Auffängerort ist hier keine stetige Funktion der Massenskala, sondern weist (bei fester elektrischer Beschleunigungsspannung und Magnetfeldstärke) im Intervall zwischen den Massenzahlen M_1 und M_2 eine Unstetigkeitsstelle auf. Je nach der Anordnung der Auffänger kann die Dispersion an dieser Stelle der Massenskala beliebig gross gemacht werden. Die Vorstellung der Massendispersion ist auch für diese Unstetigkeitsstelle gerechtfertigt, wenn man sich die zwei Auffänger a_1 und a_2 als Teile eines geeignet geformten, gemeinsamen Auffängers denkt. Voraussetzungen für ein genügendes Auflösungsvermögen einer solchen Trennanordnung sind homogene Anfangsenergie und einheitliche Anfangsrichtung der Ionen und – im allgemeinen – ein enger Eintrittsspalt B'.

Figure D.172: Heinz Ewald's March 1942 design for an electromagnetic isotope separator [G-139].



Ein optisches Analogon für dieses Trennprinzip ist vielleicht in der Erscheinung der Totalreflexion beim Übergang von Lichtstrahlen von einem optisch dichteren in ein optisch dünneres Medium zu sehen. Das Magnetfeld vertritt dabei die Rolle der Grenzschicht zwischen den beiden Medien, die bei bestimmter, konstanter Einfallsrichtung der Strahlen die schwerere Masse bzw. die grössere Wellenlänge gerade hindurchtreten lässt, während die leichtere Masse bzw. die kleinere Wellenlänge total reflektiert wird.

III. Die drei Ausführungsformen mit beliebiger "Spaltbreite" und entsprechend ausgedehnter Ionenquelle.

Die Frage, ob sich für dieses Trennprinzip eine spezielle geometrische Anordnung - geeignete Wahl der Polschuhform und des Eintrittswinkels - finden lässt, die auch bei beliebig weitem Eintrittsspalt noch genügende Auflösung ergibt und die Verwendung einer langen, schlitzförmigen Ionenquelle (ähnlich wie bei Smythe-Rumbaugh-West) gestattet, ist, wie eingangs betont, ausschlaggebend für eine genügende Herabsetzung der Raumladungsdichten und damit für die praktische Verwendbarkeit der Methode. Eine solche Anordnung lässt sich in der Tat leicht angeben: Als Polschuhbegrenzungen werden zwei konzentrische Kreise gewählt, bei senkrechtem Eintritt der Ionenstrahlen in die eine kreisförmige Begrenzung. In diesem durch Fig. 2 (S.6) schematisch dargestellten Fall ist also ein ringförmiges Magnetfeld und eine radiale Anfangsrichtung der Ionen gegeben. Die ganze Anordnung ist vollkommen rotationssymmetrisch. Eine grosse runde Ionenquelle sendet von ihrer Peripherie (zylindrischer Austrittsschlitz, Kreis mit Radius r_d = MD) aus Ionen homogener Energie radial in einer Ebene (Zeichenebene) nach allen Seiten. Diese Strahlen treten also auch senkrecht in die Magnetfeldbegrenzung b(Kreis mit Radius r_b '= MB) ein. Eingezeichnet ist z.B. der Verlauf der Strahlen DB und PQ. Bei richtig eingestellten Feldstärken tritt also die schwerere der zu trennenden Massen gerade etwa tangential aus der anderen Begrenzung des Magnetringes (Trenngrenze c, Kreis mit Radius r_c = MC) aus und wird auf dem Auffänger a_2(Kreis mit Radius r_a = MA) aufgefangen. Die leichtere Masse wird dagegen zur Seite der Ionenquelle zurückgebogen und dort auf dem Auffänger a_1 (Radius identisch mit dem der Ionenquelle) abgeschieden.

Fig. 2. Anordnung mit ringförmigem Magnetfeld, Innenione quelle und Aussenauffänger für die schwere Masse

Fig. 3. Lineare Ausführung mit langem, rechteckigem Polschuh, Grenzfall des Ringmagneten.

Fig. 4. Anordnung mit ringförmigem Magnetfeld, Aussenionenquelle und Innenauffänger für die schwere Masse.

Aus dem Beispiel Fig. 2 ergeben sich die zwei anderen geometrisch möglichen Fälle, wenn wir die Schnittpunkte D,B,C und A der vier konzentrischen Begrenzungskreise mit der y-Achse festhalten, ihren gemeinsamen Mittelpunkt M aber auf der y-Achse wandern lassen. Wenn M gegen $-\infty$ rückt, erhalten wir den in Fig. 3 dargestellten Grenzfall eines sehr langen geraden (rechteckigen) Polschuhes, auf dessen einer Seite sich die Ionenquelle sowie der Auffänger a_1 für die leichtere Masse und auf der anderen Seite der Auffänger a_2 für die schwerere Masse befindet.

Wenn dagegen in Fig. 2 M auf den positiven Teil der y-Achse über den Punkt A hinaus verschoben wird, so erhalten wir den Fall Fig. 4, dass die Ionenquelle ausserhalb des Ringmagnetfeldes liegt und die Ionen radial nach innen sendet. Der Auffänger für die schwerere Masse befindet sich dann im Innern, und die Feldstärken werden in diesem Fall so eingestellt, dass die schwerere Masse gerade streifend auf dem Auffänger auftrifft, während die leichtere daran vorbeigebogen wird.

Alle drei Möglichkeiten sind auch praktisch ausführbar, ihre Trenneigenschaftennsollen daher untersucht und miteinander verglichen werden.

IV. Berechnung des Auflösungsvermögens.

Wichtig ist zunächst eine Berechnung des zu erwartenden Auflösungsvermögens. Dieses sollte theoretisch beliebig gross sein, wenn es praktisch möglich wäre, die Forderung einer radialen Anfangsrichtung der Ionen beliebig gut zu erfüllen (Voraussetzung dabei sind allerdings Ionen hinreichend homogener Energie und die noch besonders zu prüfende Annahme, dass das Streufeld an beiden Seiten des Ringmagnetfeldes keine wesentliche Störung auf das Auflösungsvermögen ausübt). Die vorhandene Maxwell-Geschwindigkeit der Ionen und eventuell auch geringe Inhomogenitäten in der Raumladungsdichte der Ionenquelle können aber zu relativ kleinen Geschwindigkeitskomponenten quer zur radialen Richtung, d.h. in Richtung der Peripherie der Ionenquelle Anlass geben.

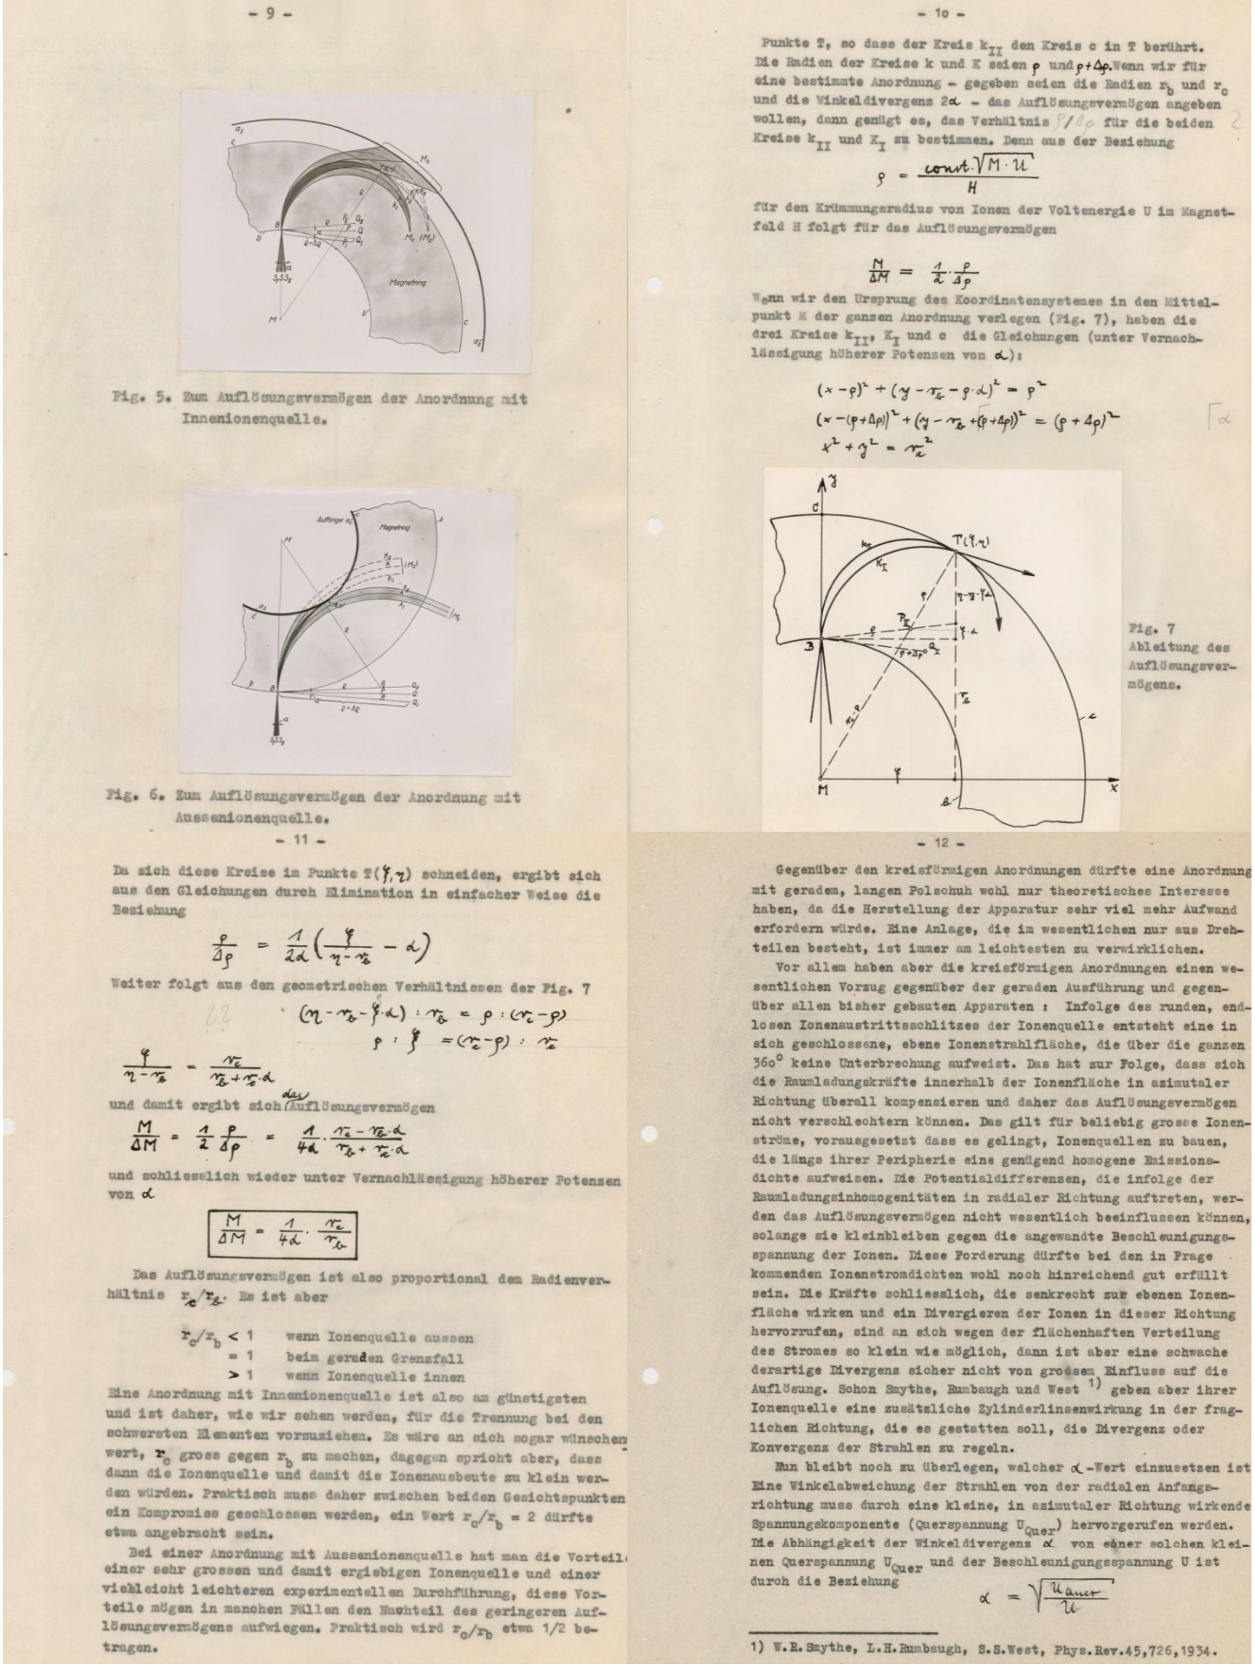
In den Figuren 5 (Ionenquelle innen) und 6 (Ionenquelle aussen) wird der Verlauf der Ionenstrahlen im Ringmagnetfeld daher dargestellt unter der Annahme, dass kleine Winkelabweichungen der maximalen Grösse $\pm\alpha$ von der im Idealfall geforderten radialen Anfangsrichtung der Ionen zugelassen sind. s sei ein bei B senkrecht zur Magnetfeldbegrenzung, d.h. radial eintretender Strahl, weiter seien s_I und s_{II} die Grenzstrahlen des durch B gehenden Büschels, deren Winkelabweichung von s laut Voraussetzung $\pm\alpha$ beträgt. Der weitere Verlauf dieser Strahlen im Magnetfeld wird für zwei verschiedene Massen M_1 und M_2 durch die Kreise k_I, k, k_{II} und K_I, K, K_{II} gegeben.

Wenn wir fordern, dass die beiden Massen im Sinne des angegebenen Trennprinzipes an der Trenngrenze c 1) gerade vollständig getrennt werden sollen, stellen wir damit ganz bestimmte geometrische Bedingungen: die inneren Grenzkreise k_{II} und K_I überschneiden sich in einem auf dem Trennkreis c liegenden

---

1) Genau genommen ist im Falle der Aussenionenquelle (Figuren 4 und 6) der Innenauffänger für die schwerere Masse die wahre Trenngrenze. Um die folgende Rechnugg nicht unnötig kompliziert zu machen, wird daher vereinfachend angenommen, wie auch aus Fig. 6 ersichtlich ist, dass der Innenauffänger a_2 praktisch den gleichen Durchmesser habe wie die innere Magnetringbegrenzung c.

Figure D.173: Heinz Ewald's March 1942 design for an electromagnetic isotope separator [G-139].



– 9 –

Fig. 5. Zum Auflösungsvermögen der Anordnung mit Innenionenquelle.

Fig. 6. Zum Auflösungsvermögen der Anordnung mit Aussenionenquelle.

– 10 –

Punkte T, so dass der Kreis k_{II} den Kreis c in T berührt. Die Radien der Kreise k und K seien ρ und $\rho+\Delta\rho$. Wenn wir für eine bestimmte Anordnung – gegeben seien die Radien r_b und r_c und die Winkeldivergenz 2α – das Auflösungsvermögen angeben wollen, dann genügt es, das Verhältnis $\rho/\Delta\rho$ für die beiden Kreise k_{II} und K_I zu bestimmen. Denn aus der Beziehung

$$\rho = \frac{\mathrm{const.}\sqrt{M \cdot U}}{H}$$

für den Krümmungsradius von Ionen der Voltenergie U im Magnetfeld H folgt für das Auflösungsvermögen

$$\frac{M}{\Delta M} = \frac{1}{\alpha} \cdot \frac{\rho}{\Delta\rho}$$

Wenn wir den Ursprung des Koordinatensystemes in den Mittelpunkt M der ganzen Anordnung verlegen (Fig. 7), haben die drei Kreise k_{II}, K_I und c die Gleichungen (unter Vernachlässigung höherer Potenzen von α):

$$(x-\rho)^2 + (y - r_b - \rho\cdot\alpha)^2 = \rho^2$$
$$(x-(\rho+\Delta\rho))^2 + (y - r_b + (\rho+\Delta\rho))^2 = (\rho+\Delta\rho)^2$$
$$x^2 + y^2 = r_c^2$$

Fig. 7 Ableitung des Auflösungsvermögens.

– 11 –

Da sich diese Kreise im Punkte $T(\xi,\eta)$ schneiden, ergibt sich aus den Gleichungen durch Elimination in einfacher Weise die Beziehung

$$\frac{\rho}{\Delta\rho} = \frac{1}{2\alpha}\left(\frac{\xi}{\eta - r_b} - \alpha\right)$$

Weiter folgt aus den geometrischen Verhältnissen der Fig. 7

$$(\eta - r_b - \xi\cdot\alpha) : r_b = \rho : (r_c - \rho)$$
$$\rho : \xi = (r_c - \rho) : r_c$$

$$\frac{\xi}{\eta - r_b} = \frac{r_c}{r_b + r_c\cdot\alpha}$$

und damit ergibt sich das Auflösungsvermögen

$$\frac{M}{\Delta M} = \frac{1}{2}\frac{\rho}{\Delta\rho} = \frac{1}{4\alpha}\cdot\frac{r_c - r_b\cdot\alpha}{r_b + r_c\cdot\alpha}$$

und schliesslich wieder unter Vernachlässigung höherer Potenzen von α

$$\boxed{\frac{M}{\Delta M} = \frac{1}{4\alpha}\cdot\frac{r_c}{r_b}}$$

Das Auflösungsvermögen ist also proportional dem Radienverhältnis r_c/r_b. Es ist aber

$r_c/r_b < 1$ wenn Ionenquelle aussen
$= 1$ beim geraden Grenzfall
> 1 wenn Ionenquelle innen

Eine Anordnung mit Innenionenquelle ist also am günstigsten und ist daher, wie wir sehen werden, für die Trennung bei den schwersten Elementen vorzuziehen. Es wäre an sich sogar wünschenswert, r_c gross gegen r_b zu machen, dagegen spricht aber, dass dann die Ionenquelle und damit die Ionenausbeute zu klein werden würden. Praktisch muss daher zwischen beiden Gesichtspunkten ein Kompromiss geschlossen werden, ein Wert $r_c/r_b = 2$ dürfte etwa angebracht sein.

Bei einer Anordnung mit Aussenionenquelle hat man die Vorteile einer sehr grossen und damit ergiebigen Ionenquelle und einer vielleicht leichteren experimentellen Durchführung, diese Vorteile mögen in manchen Fällen den Nachteil des geringeren Auflösungsvermögens aufwiegen. Praktisch wird r_c/r_b etwa 1/2 betragen.

– 12 –

Gegenüber den kreisförmigen Anordnungen dürfte eine Anordnung mit geradem, langen Polschuh wohl nur theoretisches Interesse haben, da die Herstellung der Apparatur sehr viel mehr Aufwand erfordern würde. Eine Anlage, die im wesentlichen nur aus Drehteilen besteht, ist immer am leichtesten zu verwirklichen.

Vor allem haben aber die kreisförmigen Anordnungen einen wesentlichen Vorzug gegenüber der geraden Ausführung und gegenüber allen bisher gebauten Apparaten : Infolge des runden, endlosen Ionenaustrittsschlitzes der Ionenquelle entsteht eine in sich geschlossene, ebene Ionenstrahlfläche, die über die ganzen 360° keine Unterbrechung aufweist. Das hat zur Folge, dass sich die Raumladungskräfte innerhalb der Ionenfläche in azimutaler Richtung überall kompensieren und daher das Auflösungsvermögen nicht verschlechtern können. Das gilt für beliebig grosse Ionenströme, vorausgesetzt dass es gelingt, Ionenquellen zu bauen, die längs ihrer Peripherie eine genügend homogene Emissionsdichte aufweisen. Die Potentialdifferenzen, die infolge der Raumladungsinhomogenitäten in radialer Richtung auftreten, werden das Auflösungsvermögen nicht wesentlich beeinflussen können, solange sie kleinbleiben gegen die angewandte Beschleunigungsspannung der Ionen. Diese Forderung dürfte bei den in Frage kommenden Ionenstromdichten wohl noch hinreichend gut erfüllt sein. Die Kräfte schliesslich, die senkrecht zur ebenen Ionenfläche wirken und ein Divergieren der Ionen in dieser Richtung hervorrufen, sind an sich wegen der flächenhaften Verteilung des Stromes so klein wie möglich, dann ist aber eine schwache derartige Divergenz sicher nicht von grossem Einfluss auf die Auflösung. Schon Smythe, Rumbaugh und West 1) geben aber ihrer Ionenquelle eine zusätzliche Zylinderlinsenwirkung in der fraglichen Richtung, die es gestatten soll, die Divergenz oder Konvergenz der Strahlen zu regeln.

Nun bleibt noch zu überlegen, welcher α-Wert einzusetzen ist. Eine Winkelabweichung der Strahlen von der radialen Anfangsrichtung muss durch eine kleine, in azimutaler Richtung wirkende Spannungskomponente (Querspannung U_{Quer}) hervorgerufen werden. Die Abhängigkeit der Winkeldivergenz α von einer solchen kleinen Querspannung U_{Quer} und der Beschleunigungsspannung U ist durch die Beziehung

$$\alpha = \sqrt{\frac{U_{Quer}}{U}}$$

gegeben und in Fig. 8 für die hier in Betracht kommenden Zahlenwerte von U und U_{Quer} graphisch dargestellt.

U_{Quer} kann sich aus zwei verschiedenen Anteilen zusammensetzen. Der eine ist auf die Maxwell-Boltzmannsche Geschwindigkeitsverteilung der Ionen in der Ionenquelle zurückzuführen und leicht zahlenmässig angebbar. Die mittlere Temperaturvoltgeschwindigkeit beträgt für eine Ionenquellentemperatur von 2ooo° nur o,17 Volt. Eine Zahl dieser Grössenordnung wäre also für diesen Anteil einzusetzen. Ein anderer Anteil kann durch kleine azimutale Raumladungsinhomogenitäten in der Ionenquelle zustandekommen und sich dem ersteren überlagern. Seine Grösse wird sehr von der praktisch erreichbaren Güte der Ionenquelle abhängen, es mag aber angenommen werden, dass es gelingt, ihn unter 1 Volt zu halten. Damit würde sich etwa eine Querspannung von 1 Volt ergeben, dem entspräche nach Fig. 8 bei U = 5o kV z.B. ein $\alpha = 5 \cdot 1o^{-3}$.

In Fig. 9 wird eine graphische Darstellung für die Zahlenwerte des Auflösungsvermögens in Abhängigkeit von der Winkeldivergenz α gegeben, für den geraden Grenzfall und für die Beispiele r_c/r_b = 2 und 1/2. Aus den Figuren 8 und 9 kann man ersehen, dass beispielsweise das für die Abtrennung des Uranisotopes 235 etwa erforderliche Auflösungsvermögen 8o bei U = 1oo kV eine Querspannung bis zu 4 Volt zulassen würde (Innenionenquelle). Bei U_{Quer} = 1 Volt wird man also eine sehr sichere Trennung bekommen. Wenn man aber, was durchaus möglich ist, für U_{Quer} einen kleineren Wert, z.B. etwa o,2 Volt anzusetzen hätte, dann würde unter den gleichen Bedingungen das Auflösungsvermögen 25o übersteigen, und damit wäre unter Umständen die Möglichkeit gegeben, U^{234} und U^{235} zu trennen.

Der Vollständigkeit halber soll noch der Einfluss einer kleinen Inhomogenität ΔU der Ionenenergie U auf das Auflösungsvermögen angegeben werden; das reziproke Auflösungsvermögen ist dann

$$\frac{\Delta M}{M} = 4\alpha \cdot \frac{r_b}{r_c} + \frac{\Delta U}{U}$$

Da es aber möglich sein sollte, diese Inhomogenität unter 1%. zu halten, können wir dieses Zusatzglied vernachlässigen.

V. Zusammenfassung.

Es wird eine neue Methode der magnetischen Isotopentrennung vorgeschlagen, die auf folgendem Prinzip beruht: Ionen homogener Energie treten unter bestimmter Richtung in ein homogenes Magnetfeld ein, dessen Feldstärke so abgestimmt wird, dass die schwerere der zu trennenden Massen auf der anderen Seite des Magnetfeldes gerade etwa streifend austritt, während die leichtere Masse gerade nicht austreten kann und zur Eintrittsseite zurückgebogen wird. Dieses Trennprinzip gibt bei Verwendung eines ringförmigen Magnetfeldes und eines dazu konzentrisch angeordneten, zylinderringförmigen Austrittsschlitzes der Ionenquelle folgende vorteilhafte Eigenschaften:
Die bei allen bisherigen Anordnungen mehr oder weniger kritischen Raumladungsstörungen, die Ionenausbeute und Auflösungsvermögen begrenzen, sind hier weitgehend beseitigt. Die Ionenausbeute dürfte infolge der sehr ausgedehnten Ionenquelle und der flächenhaften Verteilung des Ionenstromes bzw. der Raumladung, gemessen an der Grösse der Apparatur und des notwendigen Magnetfeldes, ein Optimum sein. Die rotationssymmetrische Anordnung bedingt, dass sich bei homogener Emissionsdichte der Ionenquelle die in azimutaler Richtung wirkenden Raumladungskräfte überall kompensieren und daher auch bei höherer Ionenstromdichte das Auflösungsvermögen nicht verschlechtern können. Die aus einer Berechnung des Auflösungsvermögens sich ergebenden Werte sind sehr günstig und dürften für die meisten praktisch vorkommenden Fälle eine sichere Trennung ergeben. Unter Umständen mag sogar die Trennung der Uranisotope 234 und 235 auf diese Weise möglich werden.

Herrn Prof. Dr. J. Mattauch, meinem Lehrer in der Massenspektrographie, möchte ich für sein förderndes und stets hilfsbereites Interesse an dieser Untersuchung meinen herzlichen Dank sagen, desgleichen Herrn Dr. A. Klemm für zahlreiche anregende Diskussionen. Herrn M. v. Ardenne bin ich für Diskussionen über die praktische Durchführbarkeit der Methode sehr verpflichtet.

für den Krümmungsradius von Ionen der Voltenergie U im Magnetfeld H folgt für das Auflösungsvermögen

$$\frac{M}{\Delta M} = \frac{1}{\alpha}\cdot\frac{\rho}{\Delta\rho}$$

Wenn wir den Ursprung des Koordinatensystemes in den Mittelpunkt M der ganzen Anordnung verlegen (Fig. 7), haben die drei Kreise k_{II}, K_I und c die Gleichungen (unter Vernachlässigung höherer Potenzen von α):

$$(x-\rho)^2 + (y - r_b - \rho\cdot\alpha)^2 = \rho^2$$

$$(x-(\rho+\Delta\rho))^2 + (y - r_b + (\rho+\Delta\rho))^2 = (\rho+\Delta\rho)^2$$

$$x^2 + y^2 = r_c^2$$

I. Der Einfluss von Ionengeschwindigkeitsverteilung und relativer Häufigkeit auf das Auflösungsvermögen.

Wird bei den beiden in Teil I+) besprochenen Ausführungsformen mit ringförmigem Magnetfeld nach H. Ewald oder bei de graden Form des Isotopentrenners vom Verfasser die Ionenquell so ausgeführt, dass die Emissionsdichte überall konstant ist so besteht die bemerkenswerte Eigenschaft, dass die Trennung in erster Näherung unabhängig vom Raumladungseinfluss ist. Dies liegt darin, dass im Fall eines Emissionsfächers unendlicher Ausdehnung die schädlichen Raumladungseinflüsse benachbarter Teilchen sich in der Fächerebene gegenseitig aufheben. Lokale Unterschiede der Ionenemissionsdichte, die praktisch nur schwer ganz zu vermeiden sein werden, können einen merklichen Beitrag zur Querspannung U_{Quer} liefern. Die Grösse dieses Beitrages ist schwer abzuschätzen. Sie wird sehr von der Güte der Ionenquelle abhängen. Nachdem grundsätzlich der Einfluss von Emissionsdichte-Unterschieden durch Herabsetzung der Emissionsdichte selbst ausgeschaltet werden kann, hat man es in der Hand durch Schliessung eines Kompromisses ihn in erträglichen Grenzen zu halten.

Aus dem oben Gesagten ergibt sich folgende Zusammensetzung der Querspannung

$$U_{Quer} = U_m \cdot k_1 \cdot k_2$$

U_m ist hierbei die mittlere Voltgeschwindigkeit der thermische Ionen, für die wir bei einer Ionenquellentemperatur von 1000

sächlich in seiner Bewegungsrichtung in einen Achsenwinkel der Größenordnung $\sqrt{1-\beta^2}$. Die Energieverluste des Elektrons durch Strahlungsstöße im Antikathodenmaterial wurden von BETHE quantenmechanisch untersucht. Wir sind also in der Lage, die Ausbeute an Bremsstrahlung bei der Bremsung der Elektronen in der Antikathode theoretisch zu ermitteln[86]. Dabei legen wir die exakte Kurve des Strahlungsquerschnittes den Berechnungen zugrunde. In Abb. 21 ist der Wirkungsgrad für die Bremsstrahlerzeugung relativ zur kinetischen Teilchenenergie als Funktion der Elektronenenergie bis 150 MeV angegeben. Dabei ist zu berücksichtigen, daß in den notwendigerweise dicken Antikathoden ein Teil der ausgesandten Bremsstrahlung wieder absorbiert wird. Eine genaue Diskussion dieser Verhältnisse gab KULENKAMPFF. Bei 150 MeV muß die Dicke der Antikathode selbst bei Blei als bremsender Substanz einige Zentimeter betragen, wenn die Elektronen hinreichend gebremst werden sollen.

Abb. 21. Ausbeute an Röntgenstrahlen an einer dicken Antikathode.

5.6 MASSENSPEKTROGRAPHEN

von

H. EWALD, Kaiser-Wilhelm-Institut für Chemie, Tailfingen, und
H. MARSCHALL, Institut für Struktur der Materie der Universität Marburg.

5.6.1 Konstruktion und Berechnung

von

H. EWALD

In den letzten Jahren fanden in Deutschland sowohl Massenspektrographen im engeren Sinne – mit Photoplatte arbeitende Präzisionsapparate zur Bestimmung der Massen und relativen Isotopenhäufigkeiten – als auch Massenspektrometer, die bei elektrometrischer Meßmethode ausschließlich Häufigkeitsbestimmungen dienen, Verwendung.

W. PAUL[87] erbaute in Göttingen ein Massenspektrometer als ausheizbare Metallkonstruktion. Wie bei dem jüngsten Apparat von NIER beträgt die Ablenkung der Strahlen im Magnetfeld 60°, bei einem mittleren Krümmungsradius von 20 cm. Eintritts- und Auffängerspalt befinden sich in 34,7 cm Entfernung von den beiderseitigen Feldbegrenzungsebenen und werden im Verhältnis 1 : 1 aufeinander abgebildet. Für die Massendispersion D in der Ebene des Auffängerspaltes gilt dann $D = 40/M$. Bei Anwendung einer Beschleunigungsspannung von $U = 1600$ Volt auf die Ionen und Annahme eines Streubereichs dieser Spannung von $\Delta U = 5$ Volt sollte sich bei einer Eintrittsschlitzweite von 0,2 mm ein Auflösungsvermögen von etwa 500 ergeben. Die zum Kraftfluß senkrechten Wände der magnetischen Ablenkkammer bestehen aus einem magnetisch weichen Eisen (Hyperm) und stellen gleichzeitig die Polschuhe dar. Die anderen Wände sind aus unmagnetischem V 2 A-Stahl (V 2 A-Supra) gefertigt und mit ersteren elektrisch verschweißt. Auf die Eintritts- und Austrittsfläche sind V 2 A-Stahlrohre von 35 mm lichter Weite aufgeschweißt. Die Enden dieser Rohre tragen die Spalte, Ionenquelle und Auffänger. Ihre Abdichtung geschieht durch mit dünnen Silberblechringen (0,1 mm) gedichtete Flansche und daran angeschmolzene Glashauben, die zugleich die notwendigen isolierten Spannungsdurchführungen aufweisen.

Da trotz Ausheizens die CO-Abgabe des Eisens nicht unter das geforderte Mindestmaß sinkt, wird für die Untersuchung leichter Gase eine Kupferablenkkammer verwendet, die aus einem innen vergoldeten Kupferrohr von 35 mm Weite besteht, das in seinem Mittelstück entsprechend gebogen ist.

Um auch bei kleinen Gasdichten genügend hohe Ionenströme zu erhalten, wurde eine Ionenquelle nach HEIL[88] verwendet, in der die Ionen durch Stoß pendelnder Elektronen von 100 bis 150 Volt-Geschwindigkeit entstehen. Zur Vermeidung vorzeitigen Auftreffens dieser Elektronen auf die Anode werden sie durch ein Magnetfeld von einigen 100 Gauß geführt. Die Ionen werden mit einer Ziehspannung von 10 bis 30 Volt aus der Quelle herausgezogen und dann nach Beschleunigung auf 1600 Volt und unter Verwendung einer geeigneten Ionenoptik auf den Eintrittsspalt konzentriert. Anfangs zeigte sich, daß eine Änderung des Pendelmagnetfeldes der Ionenquelle die Meßergebnisse der Mischungsverhältnisse beeinflußte, was durch eine Vordispersion des Ionenbündels in diesem Feld zu erklären ist. Diesem Übelstand wurde durch Verwendung kleinerer Feldstärken und Anbringung einer magnetischen Abschirmung in Form eines über die Ionenquelle gesteckten Hypermrohres abgeholfen. Die Spaltbreiten betragen meist einige Zehntel Millimeter, die Ionenströme des Hauptisotops etwa 10^{-10} Amp.

Zur Prüfung des Spektrometers wurden zunächst die Elemente Rubidium, Kalium und Thallium verwendet, deren Ionen in einer Glühanode[89] mit homogener Geschwindigkeit erzeugt werden können. Hier ist eine Verbreiterung der Linien durch Fehler in der Ionenquelle ausgeschlossen. Nach gründlicher Ausheizung des Apparates ergab sich damit die theoretisch zu erwartende Linienschärfe. Zur Prüfung der Pendelionenquelle wurde das Massenspektrogramm des Neons aufgenommen und lieferte den Beweis für ihre Brauchbarkeit.

Die mit dieser und den im folgenden beschriebenen Apparaturen erhaltenen Meßergebnisse werden an anderer Stelle besprochen, vgl. Ziff. 3. 2.

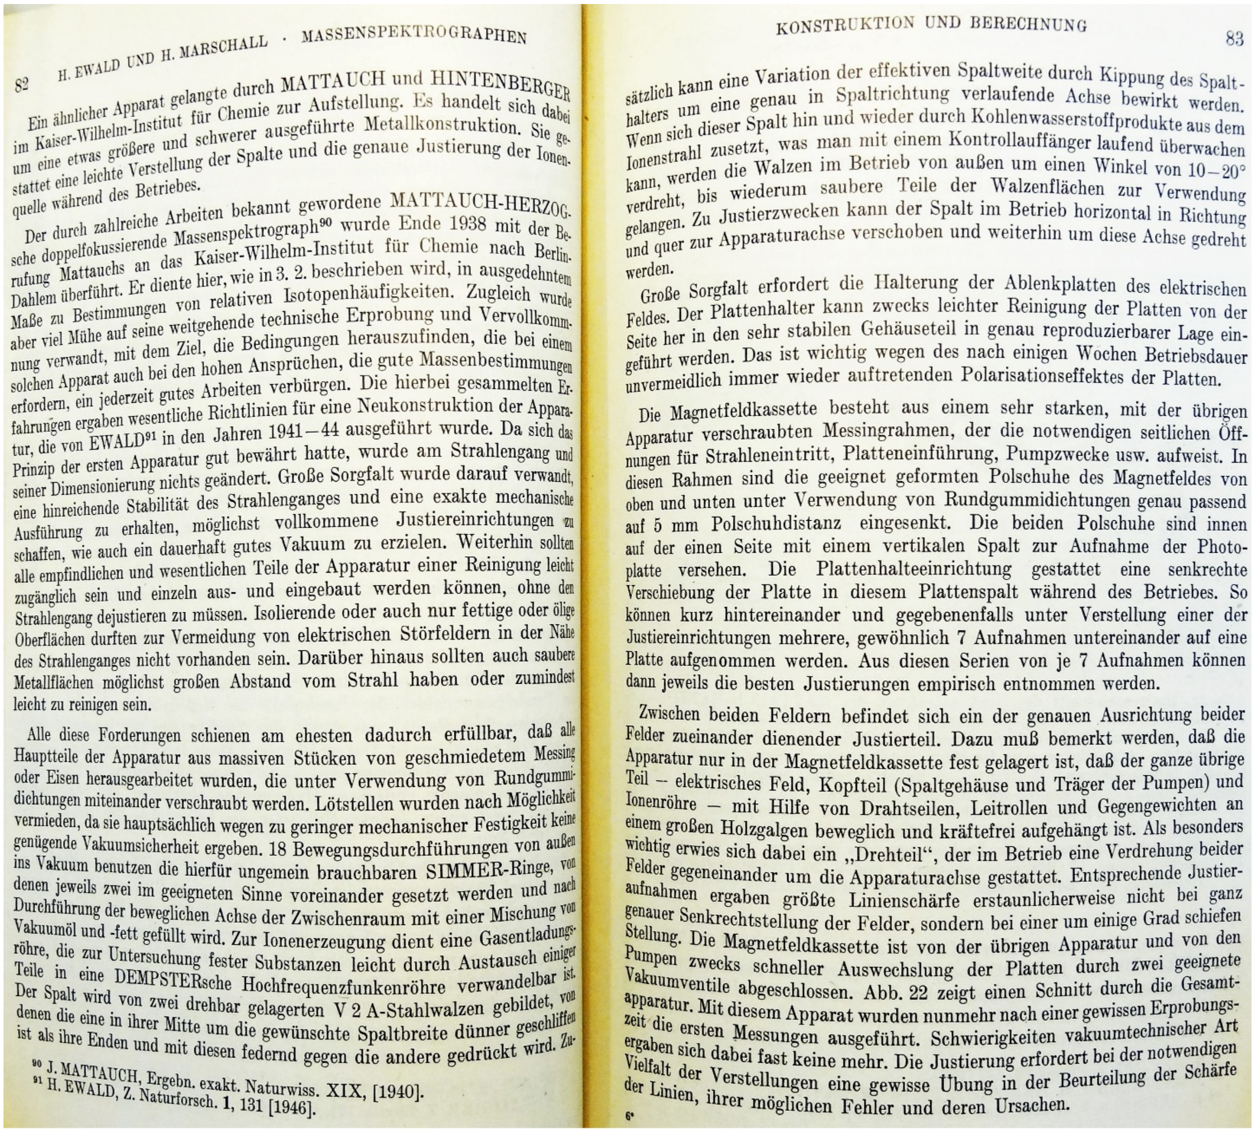
Figure D.203: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



Ein ähnlicher Apparat gelangte durch MATTAUCH und HINTENBERGER im Kaiser-Wilhelm-Institut für Chemie zur Aufstellung. Es handelt sich dabei um eine etwas größere und schwerer ausgeführte Metallkonstruktion. Sie gestattet eine leichte Verstellung der Spalte und die genaue Justierung der Ionenquelle während des Betriebes.

Der durch zahlreiche Arbeiten bekannt gewordene MATTAUCH-HERZOGsche doppelfokussierende Massenspektrograph[90] wurde Ende 1938 mit der Berufung Mattauchs an das Kaiser-Wilhelm-Institut für Chemie nach Berlin-Dahlem überführt. Er diente hier, wie in 3. 2. beschrieben wird, in ausgedehntem Maße zu Bestimmungen von relativen Isotopenhäufigkeiten. Zugleich wurde aber viel Mühe auf seine weitgehende technische Erprobung und Vervollkommnung verwandt, mit dem Ziel, die Bedingungen herauszufinden, die bei einem solchen Apparat auch bei den hohen Ansprüchen, die gute Massenbestimmungen erfordern, ein jederzeit gutes Arbeiten verbürgen. Die hierbei gesammelten Erfahrungen ergaben wesentliche Richtlinien für eine Neukonstruktion der Apparatur, die von EWALD[91] in den Jahren 1941–44 ausgeführt wurde. Da sich das Prinzip der ersten Apparatur gut bewährt hatte, wurde am Strahlengang und seiner Dimensionierung nichts geändert. Große Sorgfalt wurde darauf verwandt, eine hinreichende Stabilität des Strahlenganges und eine exakte mechanische Ausführung zu erhalten, möglichst vollkommene Justiereinrichtungen zu schaffen, wie auch ein dauerhaft gutes Vakuum zu erzielen. Weiterhin sollten alle empfindlichen und wesentlichen Teile der Apparatur einer Reinigung leicht zugänglich sein und einzeln aus- und eingebaut werden können, ohne den Strahlengang dejustieren zu müssen. Isolierende oder auch nur fettige oder ölige Oberflächen durften zur Vermeidung von elektrischen Störfeldern in der Nähe des Strahlenganges nicht vorhanden sein. Darüber hinaus sollten auch saubere Metallflächen möglichst großen Abstand vom Strahl haben oder zumindest leicht zu reinigen sein.

Alle diese Forderungen schienen am ehesten dadurch erfüllbar, daß alle Hauptteile der Apparatur aus massiven Stücken von geschmiedetem Messing oder Eisen herausgearbeitet wurden, die unter Verwendung von Rundgummidichtungen miteinander verschraubt werden. Lötstellen wurden nach Möglichkeit vermieden, da sie hauptsächlich wegen zu geringer mechanischer Festigkeit keine genügende Vakuumsicherheit ergeben. 18 Bewegungsdurchführungen von außen ins Vakuum benutzen die hierfür ungemein brauchbaren SIMMER-Ringe, von denen jeweils zwei im geeigneten Sinne voreinander gesetzt werden und nach Durchführung der beweglichen Achse der Zwischenraum mit einer Mischung von Vakuumöl und -fett gefüllt wird. Zur Ionenerzeugung dient eine Gasentladungsröhre, die zur Untersuchung fester Substanzen leicht durch Austausch einiger Teile in eine DEMPSTERsche Hochfrequenzfunkenröhre verwandelbar ist. Der Spalt wird von zwei drehbar gelagerten V 2 A-Stahlwalzen gebildet, von denen die eine in ihrer Mitte um die gewünschte Spaltbreite dünner geschliffen ist als ihre Enden und mit diesen federnd gegen die andere gedrückt wird. Zusätzlich kann eine Variation der effektiven Spaltweite durch Kippung des Spalthalters um eine genau in Spaltrichtung verlaufende Achse bewirkt werden. Wenn sich dieser Spalt hin und wieder durch Kohlenwasserstoffprodukte aus dem Ionenstrahl zusetzt, was man mit einem Kontrollauffänger laufend überwachen kann, werden die Walzen im Betrieb von außen um einen Winkel von 10–20° verdreht, bis wiederum saubere Teile der Walzenflächen zur Verwendung gelangen. Zu Justierzwecken kann der Spalt im Betrieb horizontal in Richtung und quer zur Apparaturachse verschoben und weiterhin um diese Achse gedreht werden.

Große Sorgfalt erfordert die Halterung der Ablenkplatten des elektrischen Feldes. Der Plattenhalter kann zwecks leichter Reinigung der Platten von der Seite her in den sehr stabilen Gehäuseteil in genau reproduzierbarer Lage eingeführt werden. Das ist wichtig wegen des nach einigen Wochen Betriebsdauer unvermeidlich immer wieder auftretenden Polarisationseffektes der Platten.

Die Magnetfeldkassette besteht aus einem sehr starken, mit der übrigen Apparatur verschraubten Messingrahmen, der die notwendigen seitlichen Öffnungen für Strahleneintritt, Platteneinführung, Pumpzwecke usw. aufweist. In diesen Rahmen sind die geeignet geformten Polschuhe des Magnetfeldes von oben und unten unter Verwendung von Rundgummidichtungen genau passend auf 5 mm Polschuhdistanz eingesenkt. Die beiden Polschuhe sind innen auf der einen Seite mit einem vertikalen Spalt zur Aufnahme der Photoplatte versehen. Die Plattenhalteeinrichtung gestattet eine senkrechte Verschiebung der Platte in diesem Plattenspalt während des Betriebes. So können kurz hintereinander und gegebenenfalls unter Verstellung einer der Justiereinrichtungen mehrere, gewöhnlich 7 Aufnahmen untereinander auf eine Platte aufgenommen werden. Aus diesen Serien von je 7 Aufnahmen können dann jeweils die besten Justierungen empirisch entnommen werden.

Zwischen beiden Feldern befindet sich ein der genauen Ausrichtung beider Felder zueinander dienender Justierteil. Dazu muß bemerkt werden, daß die Apparatur nur in der Magnetfeldkassette fest gelagert ist, daß der ganze übrige Teil – elektrisches Feld, Kopfteil (Spaltgehäuse und Träger der Pumpen) und Ionenröhre – mit Hilfe von Drahtseilen, Leitrollen und Gegengewichten an einem großen Holzgalgen beweglich und kräftefrei aufgehängt ist. Als besonders wichtig erwies sich dabei ein ,,Drehteil", der im Betrieb eine Verdrehung beider Felder gegeneinander um die Apparaturachse gestattet. Entsprechende Justieraufnahmen ergaben größte Linienschärfe erstaunlicherweise nicht bei ganz genauer Senkrechtstellung der Felder, sondern bei einer um einige Grad schiefen Stellung. Die Magnetfeldkassette ist von der übrigen Apparatur und von den Pumpen zwecks schneller Auswechslung der Platten durch zwei geeignete Vakuumventile abgeschlossen. Abb. 22 zeigt einen Schnitt durch die Gesamtapparatur. Mit diesem Apparat wurden nunmehr nach einer gewissen Erprobungszeit die ersten Messungen ausgeführt. Schwierigkeiten vakuumtechnischer Art ergaben sich dabei fast keine mehr. Die Justierung erfordert bei der notwendigen Vielfalt der Verstellungen eine gewisse Übung in der Beurteilung der Schärfe der Linien, ihrer möglichen Fehler und deren Ursachen.

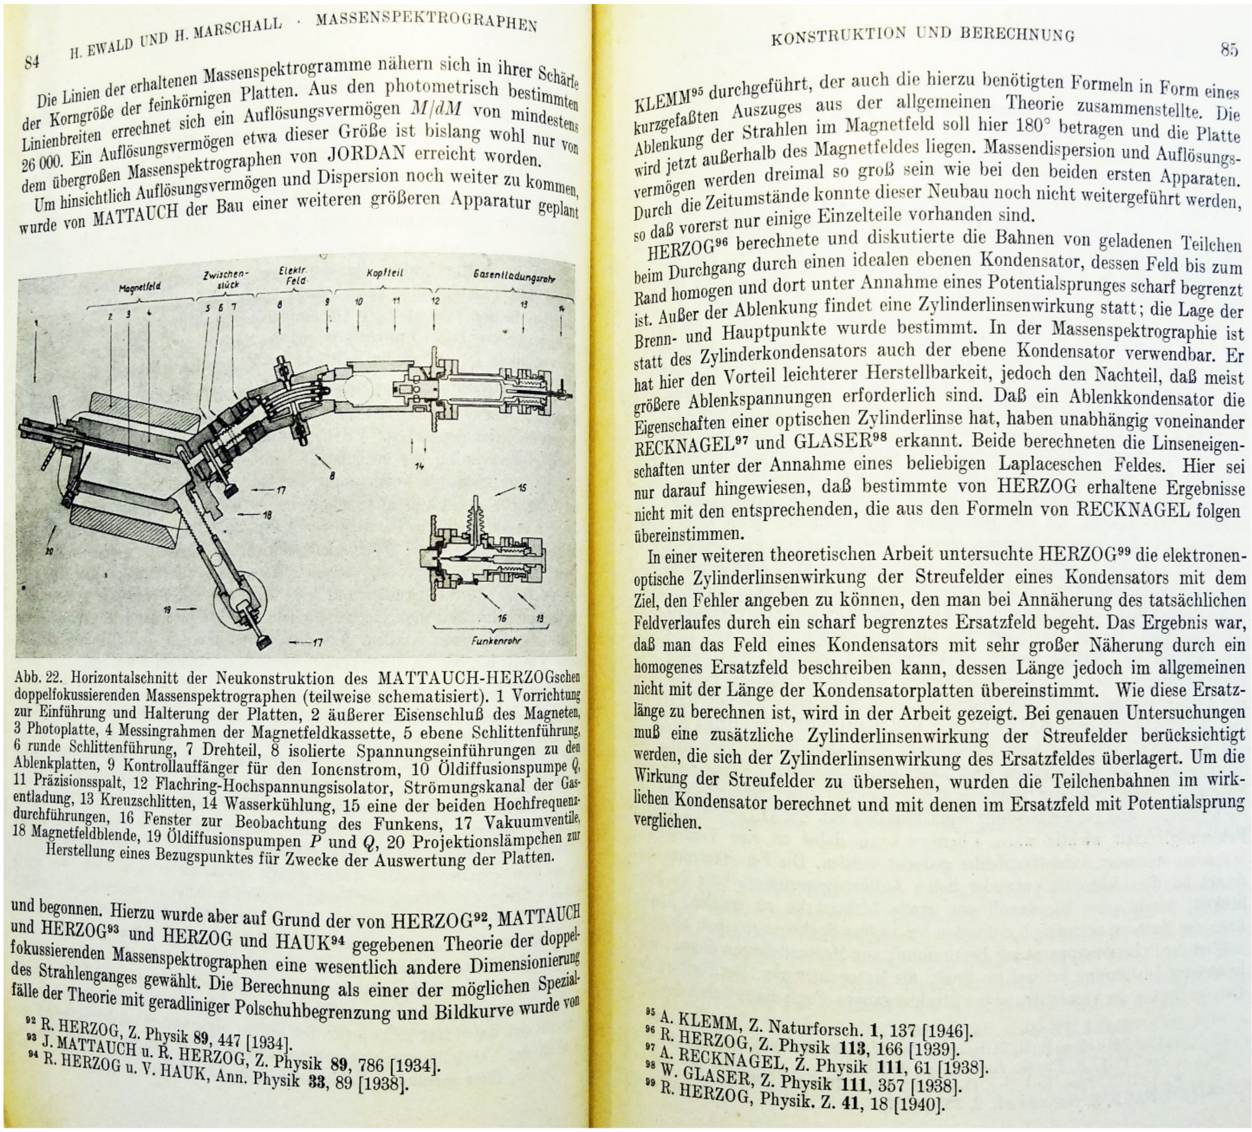
Figure D.204: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



Die Linien der erhaltenen Massenspektrogramme nähern sich in ihrer Schärfe der Korngröße der feinkörnigen Platten. Aus den photometrisch bestimmten Linienbreiten errechnet sich ein Auflösungsvermögen M/dM von mindestens 26 000. Ein Auflösungsvermögen etwa dieser Größe ist bislang wohl nur von dem übergroßen Massenspektrographen von JORDAN erreicht worden.

Um hinsichtlich Auflösungsvermögen und Dispersion noch weiter zu kommen, wurde von MATTAUCH der Bau einer weiteren größeren Apparatur geplant und begonnen. Hierzu wurde aber auf Grund der von HERZOG[92], MATTAUCH und HERZOG[93] und HERZOG und HAUK[94] gegebenen Theorie der doppelfokussierenden Massenspektrographen eine wesentlich andere Dimensionierung des Strahlenganges gewählt. Die Berechnung als einer der möglichen Spezialfälle der Theorie mit geradliniger Polschuhbegrenzung und Bildkurve wurde von KLEMM[95] durchgeführt, der auch die hierzu benötigten Formeln in Form eines kurzgefaßten Auszuges aus der allgemeinen Theorie zusammenstellte. Die Ablenkung der Strahlen im Magnetfeld soll hier 180° betragen und die Platte wird jetzt außerhalb des Magnetfeldes liegen. Massendispersion und Auflösungsvermögen werden dreimal so groß sein wie bei den beiden ersten Apparaten. Durch die Zeitumstände konnte dieser Neubau noch nicht weitergeführt werden, so daß vorerst nur einige Einzelteile vorhanden sind.

Abb. 22. Horizontalschnitt der Neukonstruktion des MATTAUCH-HERZOGschen doppelfokussierenden Massenspektrographen (teilweise schematisiert). 1 Vorrichtung zur Einführung und Halterung der Platten, 2 äußerer Eisenschluß des Magneten, 3 Photoplatte, 4 Messingrahmen der Magnetfeldkassette, 5 ebene Schlittenführung, 6 runde Schlittenführung, 7 Drehteil, 8 isolierte Spannungseinführungen zu den Ablenkplatten, 9 Kontrollauffänger für den Ionenstrom, 10 Öldiffusionspumpe Q, 11 Präzisionsspalt, 12 Flachring-Hochspannungsisolator, Strömungskanal der Gasentladung, 13 Kreuzschlitten, 14 Wasserkühlung, 15 eine der beiden Hochfrequenzdurchführungen, 16 Fenster zur Beobachtung des Funkens, 17 Vakuumventile, 18 Magnetfeldblende, 19 Öldiffusionspumpen P und Q, 20 Projektionslämpchen zur Herstellung eines Bezugspunktes für Zwecke der Auswertung der Platten.

HERZOG[96] berechnete und diskutierte die Bahnen von geladenen Teilchen beim Durchgang durch einen idealen ebenen Kondensator, dessen Feld bis zum Rand homogen und dort unter Annahme eines Potentialsprunges scharf begrenzt ist. Außer der Ablenkung findet eine Zylinderlinsenwirkung statt; die Lage der Brenn- und Hauptpunkte wurde bestimmt. In der Massenspektrographie ist statt des Zylinderkondensators auch der ebene Kondensator verwendbar. Er hat hier den Vorteil leichterer Herstellbarkeit, jedoch den Nachteil, daß meist größere Ablenkspannungen erforderlich sind. Daß ein Ablenkkondensator die Eigenschaften einer optischen Zylinderlinse hat, haben unabhängig voneinander RECKNAGEL[97] und GLASER[98] erkannt. Beide berechneten die Linseneigenschaften unter der Annahme eines beliebigen Laplaceschen Feldes. Hier sei nur darauf hingewiesen, daß bestimmte von HERZOG erhaltene Ergebnisse nicht mit den entsprechenden, die aus den Formeln von RECKNAGEL folgen übereinstimmen.

In einer weiteren theoretischen Arbeit untersuchte HERZOG[99] die elektronenoptische Zylinderlinsenwirkung der Streufelder eines Kondensators mit dem Ziel, den Fehler angeben zu können, den man bei Annäherung des tatsächlichen Feldverlaufes durch ein scharf begrenztes Ersatzfeld begeht. Das Ergebnis war, daß man das Feld eines Kondensators mit sehr großer Näherung durch ein homogenes Ersatzfeld beschreiben kann, dessen Länge jedoch im allgemeinen nicht mit der Länge der Kondensatorplatten übereinstimmt. Wie diese Ersatzlänge zu berechnen ist, wird in der Arbeit gezeigt. Bei genauen Untersuchungen muß eine zusätzliche Zylinderlinsenwirkung der Streufelder berücksichtigt werden, die sich der Zylinderlinsenwirkung des Ersatzfeldes überlagert. Um die Wirkung der Streufelder zu übersehen, wurden die Teilchenbahnen im wirklichen Kondensator berechnet und mit denen im Ersatzfeld mit Potentialsprung verglichen.

5.6.2 Gaußsche Dioptrik und Bildfehlertheorie eines Massenspektrographen[100]

von

H. MARSCHALL

In der Arbeit wird der Versuch unternommen, analog zur Licht- und Elektronenoptik eine Ionenoptik zu begründen, die als Fundament für zukünftige massenspektrograhische Entwicklungsarbeit dienen soll. Dabei war der Gedanke maßgebend, daß auch die massenspektrographischen Geräte im Laufe der Zeit eine Entwicklung bereits erfahren haben und noch erfahren dürften, die derjenigen der optischen Spektralapparate in vieler Hinsicht parallel laufen dürfte. Die Lage ist allerdings insofern einfacher, als die Beugungsphänomene, welche durch den Wellencharakter der Strahlung hervorgerufen werden, im Gegensatz zur Lichtoptik ganz zurücktreten. Dagegen bleibt eine theoretische Grundlage auszuarbeiten, die alle innerhalb der geometrischen Optik auftretenden Linsenfehler (wie Aberration, Astigmatismus und dgl.) sowie als Analogon zur Chromasie die von der Geschwindigkeitsdispersion herrührenden Bildfehler zu übersehen gestattet und darüber hinaus Vorschläge zu ihrer Korrektur machen kann. Dieses umfangreiche Programm ist in der vorstehenden Arbeit insofern nur teilweise verwirklicht, als die Beseitigung der Bildfehler noch offen bleibt. Dagegen ist die genaue Analyse eines doppelfokussierenden Ablenkorgans, bestehend aus der Überlagerung eines elektrischen und magnetischen Feldes, die beide am gleichen Ort auf die Korpuskularstrahlen einwirken, durchgeführt, wobei hinsichtlich des Aufbaus beider Felder keinerlei spezielle Voraussetzungen getroffen sind. So ist im Gegensatz zur Herzogschen Arbeit von 1934, die dem Aufbau des Mattauchschen Spektrographen zugrunde liegt, auch eine Berücksichtigung der stets unvermeidlichen Streufelder möglich. Die bis jetzt zur Ausführung gelangten doppelfokussierenden Spektralgeräte von HERZOG und MATTAUCH[93], von BAINBRIDGE und JORDAN[101], von DEMPSTER[102] und von ASTON[103] sind vom Standpunkt der Abbildungstechnik Zylinderlinsensysteme. Im vorliegenden Fall kann durch besondere Formgebung der Ablenkelektroden bzw. der magnetischen Polschuhe eine Punktabbildung erreicht werden, was zur Vermeidung einer kürzlich von EWALD[103a] diskutierten Fehlermöglichkeit wichtig wäre. Überdies kann dabei an eine Verringerung besonders störender Abbildungsfehler gedacht werden. Die Fehlerkorrektur bedeutet für die Lichtoptik entweder hohes Auflösungsvermögen oder die Möglichkeit, durch weite Blendenöffnung große Lichtstärke zu erzielen. Analog kann der Massenspektrograph entweder bei engem Spektrometerspalt als hochauflösender Präzisionsapparat zur Bestimmung von Massendefekten dienen, oder, in anderer Ausführung bei weitem Spalt, als Isotopentrenner. Der Nachteil des Gerätes liegt in der Vignettierung des Strahlenganges durch die zwischen den Polschuhen befindlichen Kondensatorplatten, so daß man nur einen beschränkten Massenbereich (in praxi etwa $\Delta M/M = \pm 8\%$) auf die Photoplatte bekommt.

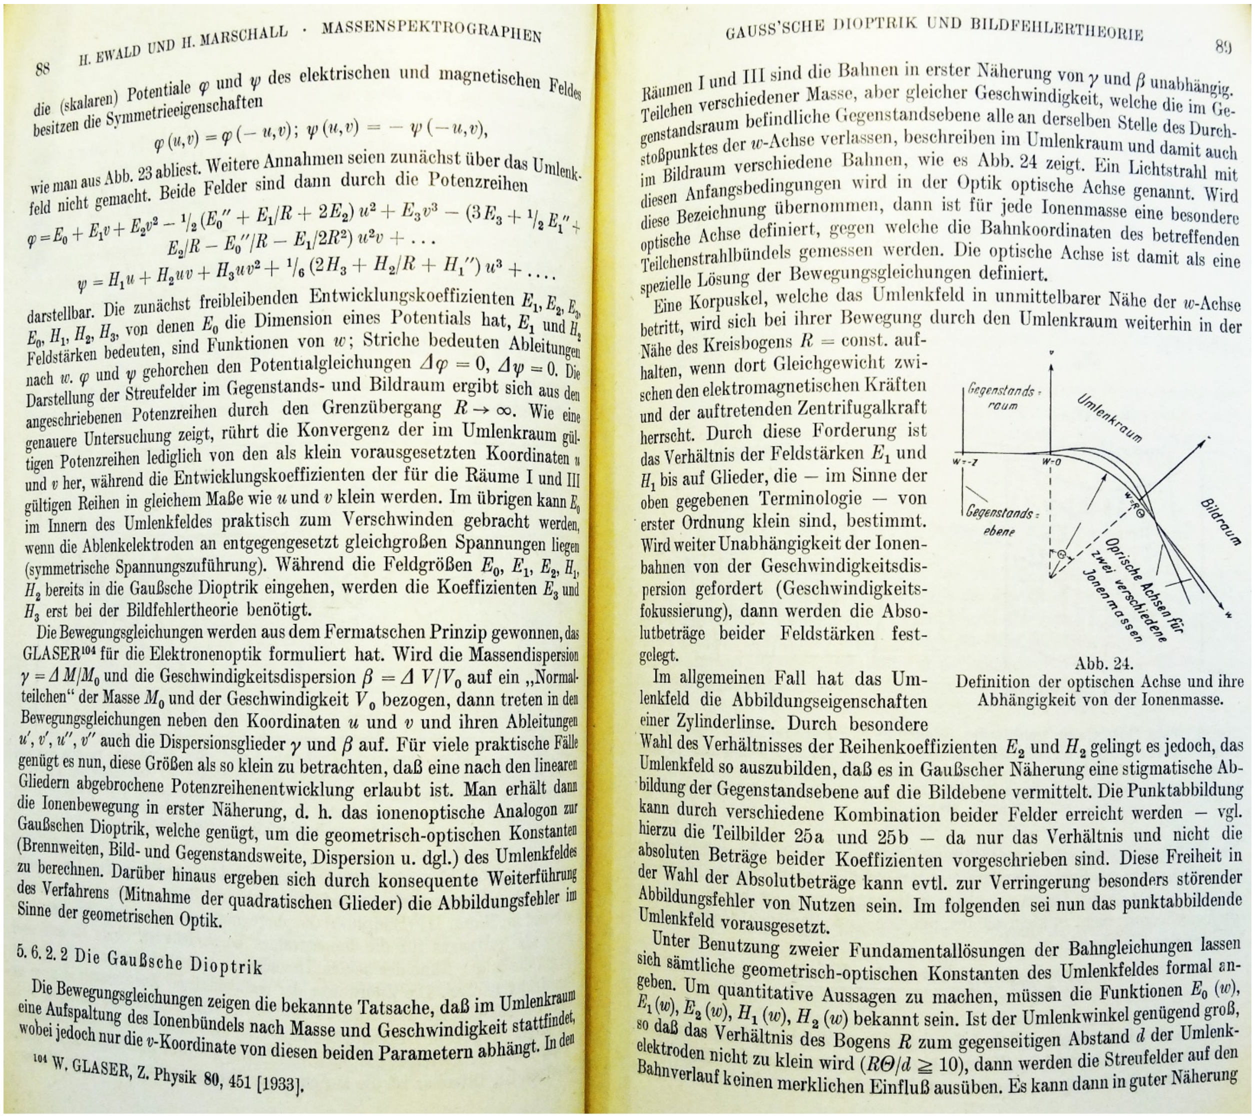
Da das Umlenkfeld einen niedrigeren Symmetriegrad aufweist als die rotationssymmetrischen Abbildungssysteme, treten auch Abbildungsfehler niedrigerer Ordnung auf: an Stelle der Abbildungsfehler dritter Ordnung im Falle drehsymmetrischer Abbildungsorgane, treten hier Abbildungsfehler zweiter Ordnung. Dies erfordert einmal die Durchführung einer neuen Systematik und Terminologie der Bildfehler, und es bedingt andererseits eine schlechtere Abbildungsqualität, als man sie von Abbildungen durch rotationssymmetrische Linsen gewohnt ist, sofern es nicht gelingt, eine Korrektur dieser Fehler vorzunehmen.

5.6.2.1 Die Durchführung des Programms

Abb. 23 zeigt in zwei schematisierten Teilbildern die Polschuhe und die Elektrodenanordnung des Umlenkfeldes. Bei dem praktisch ausgeführten Gerät befinden sich die Ablenkelektroden zwischen den Polschuhen. Die Ionenquelle mit dem Spektrometerspalt befindet sich im Raum I (Gegenstandsraum), während im Raum III (Bildraum) die photographische Platte bzw. der Faraday-Käfig als Auffänger für die Ionenstrahlen angebracht ist. Beide Räume sind bis auf die in der Nähe der beiden Trennebenen zum Umlenkraum auftretenden Streufelder feldfrei. Die Zuordnung der rechtwinkligen Koordinaten u, v, w zu dem Umlenkfeld ist aus Abb. 23 ersichtlich. Die Korpuskeln bewegen sich auf ihrem Weg vom Gegenstandsraum über den Umlenkraum zum Bildraum in der Nähe der w-Achse, die im Umlenkraum mit dem Kreisbogen $R =$ const. identisch ist. Offenbar ist die w-Achse eine Symmetrieachse des Umlenkfeldes;

Abb. 23. Das elektromagnetische Umlenkfeld und seine Zuordnung zu den Koordinaten u, v, w. Die linke Abbildung zeigt die Anordnung der Polschuhe des Umlenkmagneten, während in der rechten eine Elektrodenanordnung zur Erzeugung des elektrischen Radialfeldes dargestellt ist. Die Definition der Räume I, II und III geht aus beiden Figuren hervor.

Figure D.206: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



88 H. EWALD UND H. MARSCHALL · MASSENSPEKTROGRAPHEN

die (skalaren) Potentiale φ und ψ des elektrischen und magnetischen Feldes besitzen die Symmetrieeigenschaften

$$\varphi(u,v) = \varphi(-u,v); \quad \psi(u,v) = -\psi(-u,v),$$

wie man aus Abb. 23 abliest. Weitere Annahmen seien zunächst über das Umlenkfeld nicht gemacht. Beide Felder sind dann durch die Potenzreihen

$$\varphi = E_0 + E_1 v + E_2 v^2 - {}^1/_2 (E_0'' + E_1/R + 2E_2)\, u^2 + E_3 v^3 - (3E_3 + {}^1/_2 E_1'' + E_2/R - E_0''/R - E_1/2R^2)\, u^2 v + \ldots$$

$$\psi = H_1 u + H_2 uv + H_3 uv^2 + {}^1/_6 (2H_3 + H_2/R + H_1'')\, u^3 + \ldots.$$

darstellbar. Die zunächst freibleibenden Entwicklungskoeffizienten $E_1, E_2, E_3, E_0, H_1, H_2, H_3$, von denen E_0 die Dimension eines Potentials hat, E_1 und H_2 Feldstärken bedeuten, sind Funktionen von w; Striche bedeuten Ableitungen nach w. φ und ψ gehorchen den Potentialgleichungen $\Delta\varphi = 0$, $\Delta\psi = 0$. Die Darstellung der Streufelder im Gegenstands- und Bildraum ergibt sich aus den angeschriebenen Potenzreihen durch den Grenzübergang $R \to \infty$. Wie eine genauere Untersuchung zeigt, rührt die Konvergenz der im Umlenkraum gültigen Potenzreihen lediglich von den als klein vorausgesetzten Koordinaten u und v her, während die Entwicklungskoeffizienten der für die Räume I und III gültigen Reihen in gleichem Maße wie u und v klein werden. Im übrigen kann E_0 im Innern des Umlenkfeldes praktisch zum Verschwinden gebracht werden, wenn die Ablenkelektroden an entgegengesetzt gleichgroßen Spannungen liegen (symmetrische Spannungszuführung). Während die Feldgrößen E_0, E_1, E_2, H_1, H_2 bereits in die Gaußsche Dioptrik eingehen, werden die Koeffizienten E_3 und H_3 erst bei der Bildfehlertheorie benötigt.

Die Bewegungsgleichungen werden aus dem Fermatschen Prinzip gewonnen, das GLASER[104] für die Elektronenoptik formuliert hat. Wird die Massendispersion $\gamma = \Delta M/M_0$ und die Geschwindigkeitsdispersion $\beta = \Delta V/V_0$ auf ein „Normalteilchen" der Masse M_0 und der Geschwindigkeit V_0 bezogen, dann treten in den Bewegungsgleichungen neben den Koordinaten u und v und ihren Ableitungen u', v', u'', v'' auch die Dispersionsglieder γ und β auf. Für viele praktische Fälle genügt es nun, diese Größen als so klein zu betrachten, daß eine nach den linearen Gliedern abgebrochene Potenzreihenentwicklung erlaubt ist. Man erhält dann die Ionenbewegung in erster Näherung, d. h. das ionenoptische Analogon zur Gaußschen Dioptrik, welche genügt, um die geometrisch-optischen Konstanten (Brennweiten, Bild- und Gegenstandsweite, Dispersion u. dgl.) des Umlenkfeldes zu berechnen. Darüber hinaus ergeben sich durch konsequente Weiterführung des Verfahrens (Mitnahme der quadratischen Glieder) die Abbildungsfehler im Sinne der geometrischen Optik.

5. 6. 2. 2 Die Gaußsche Dioptrik

Die Bewegungsgleichungen zeigen die bekannte Tatsache, daß im Umlenkraum eine Aufspaltung des Ionenbündels nach Masse und Geschwindigkeit stattfindet, wobei jedoch nur die v-Koordinate von diesen beiden Parametern abhängt. In den Räumen I und III sind die Bahnen in erster Näherung von γ und β unabhängig. Teilchen verschiedener Masse, aber gleicher Geschwindigkeit, welche die im Gegenstandsraum befindliche Gegenstandsebene alle an derselben Stelle des Durchstoßpunktes der w-Achse verlassen, beschreiben im Umlenkraum und damit auch im Bildraum verschiedene Bahnen, wie es Abb. 24 zeigt. Ein Lichtstrahl mit diesen Anfangsbedingungen wird in der Optik optische Achse genannt. Wird diese Bezeichnung übernommen, dann ist für jede Ionenmasse eine besondere optische Achse definiert, gegen welche die Bahnkoordinaten des betreffenden Teilchenstrahlbündels gemessen werden. Die optische Achse ist damit als eine spezielle Lösung der Bewegungsgleichungen definiert.

Eine Korpuskel, welche das Umlenkfeld in unmittelbarer Nähe der w-Achse betritt, wird sich bei ihrer Bewegung durch den Umlenkraum weiterhin in der Nähe des Kreisbogens R = const. aufhalten, wenn dort Gleichgewicht zwischen den elektromagnetischen Kräften und der auftretenden Zentrifugalkraft herrscht. Durch diese Forderung ist das Verhältnis der Feldstärken E_1 und H_1 bis auf Glieder, die — im Sinne der oben gegebenen Terminologie — von erster Ordnung klein sind, bestimmt. Wird weiter Unabhängigkeit der Ionenbahnen von der Geschwindigkeitsdispersion gefordert (Geschwindigkeitsfokussierung), dann werden die Absolutbeträge beider Feldstärken festgelegt.

Abb. 24.
Definition der optischen Achse und ihre Abhängigkeit von der Ionenmasse.

Im allgemeinen Fall hat das Umlenkfeld die Abbildungseigenschaften einer Zylinderlinse. Durch besondere Wahl des Verhältnisses der Reihenkoeffizienten E_2 und H_2 gelingt es jedoch, das Umlenkfeld so auszubilden, daß es in Gaußscher Näherung eine stigmatische Abbildung der Gegenstandsebene auf die Bildebene vermittelt. Die Punktabbildung kann durch verschiedene Kombination beider Felder erreicht werden — vgl. hierzu die Teilbilder 25a und 25b — da nur das Verhältnis und nicht die absoluten Beträge beider Koeffizienten vorgeschrieben sind. Diese Freiheit in der Wahl der Absolutbeträge kann evtl. zur Verringerung besonders störender Abbildungsfehler von Nutzen sein. Im folgenden sei nun das punktabbildende Umlenkfeld vorausgesetzt.

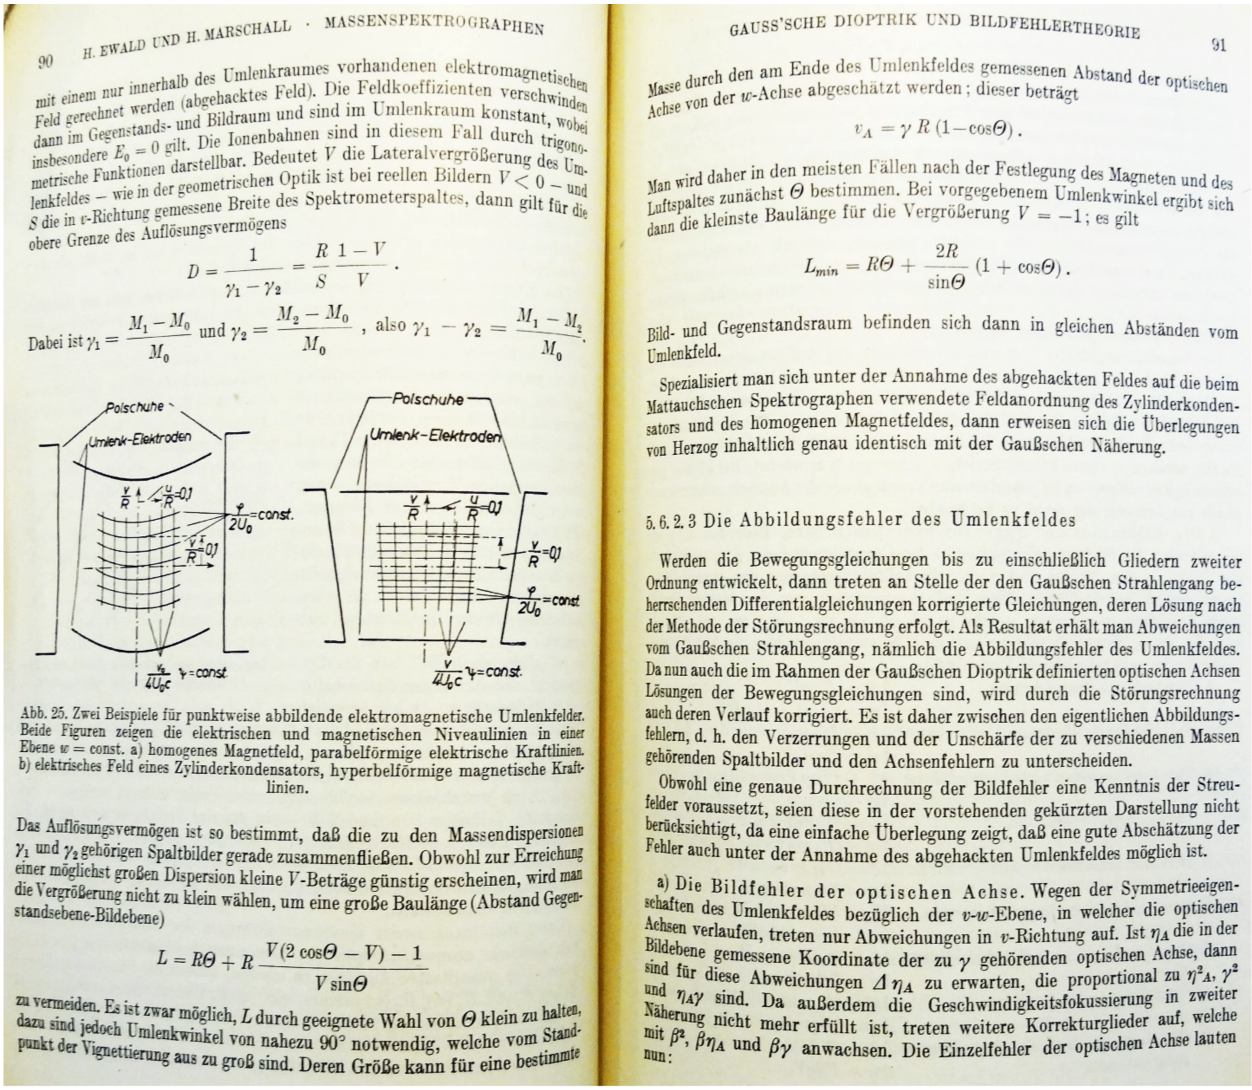
Unter Benutzung zweier Fundamentallösungen der Bahngleichungen lassen sich sämtliche geometrisch-optischen Konstanten des Umlenkfeldes formal angeben. Um quantitative Aussagen zu machen, müssen die Funktionen $E_0(w)$, $E_1(w)$, $E_2(w)$, $H_1(w)$, $H_2(w)$ bekannt sein. Ist der Umlenkwinkel genügend groß, so daß das Verhältnis des Bogens R zum gegenseitigen Abstand d der Umlenkelektroden nicht zu klein wird ($R\Theta/d \geqq 10$), dann werden die Streufelder auf den Bahnverlauf keinen merklichen Einfluß ausüben. Es kann dann in guter Näherung

---

[104] W. GLASER, Z. Physik **80**, 451 [1933].

89 GAUSS'SCHE DIOPTRIK UND BILDFEHLERTHEORIE

Figure D.207: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



mit einem nur innerhalb des Umlenkraumes vorhandenen elektromagnetischen Feld gerechnet werden (abgehacktes Feld). Die Feldkoeffizienten verschwinden dann im Gegenstands- und Bildraum und sind im Umlenkraum konstant, wobei insbesondere $E_0 = 0$ gilt. Die Ionenbahnen sind in diesem Fall durch trigonometrische Funktionen darstellbar. Bedeutet V die Lateralvergrößerung des Umlenkfeldes – wie in der geometrischen Optik ist bei reellen Bildern $V < 0$ – und S die in v-Richtung gemessene Breite des Spektrometerspaltes, dann gilt für die obere Grenze des Auflösungsvermögens

$$D = \frac{1}{\gamma_1 - \gamma_2} = \frac{R}{S}\,\frac{1-V}{V}\,.$$

Dabei ist $\gamma_1 = \dfrac{M_1 - M_0}{M_0}$ und $\gamma_2 = \dfrac{M_2 - M_0}{M_0}$, also $\gamma_1 - \gamma_2 = \dfrac{M_1 - M_2}{M_0}$.

Abb. 25. Zwei Beispiele für punktweise abbildende elektromagnetische Umlenkfelder. Beide Figuren zeigen die elektrischen und magnetischen Niveaulinien in einer Ebene $w = \text{const.}$ a) homogenes Magnetfeld, parabelförmige elektrische Kraftlinien. b) elektrisches Feld eines Zylinderkondensators, hyperbelförmige magnetische Kraftlinien.

Das Auflösungsvermögen ist so bestimmt, daß die zu den Massendispersionen γ_1 und γ_2 gehörigen Spaltbilder gerade zusammenfließen. Obwohl zur Erreichung einer möglichst großen Dispersion kleine V-Beträge günstig erscheinen, wird man die Vergrößerung nicht zu klein wählen, um eine große Baulänge (Abstand Gegenstandsebene-Bildebene)

$$L = R\Theta + R\,\frac{V(2\cos\Theta - V) - 1}{V\sin\Theta}$$

zu vermeiden. Es ist zwar möglich, L durch geeignete Wahl von Θ klein zu halten, dazu sind jedoch Umlenkwinkel von nahezu 90° notwendig, welche vom Standpunkt der Vignettierung aus zu groß sind. Deren Größe kann für eine bestimmte

Masse durch den am Ende des Umlenkfeldes gemessenen Abstand der optischen Achse von der w-Achse abgeschätzt werden; dieser beträgt

$$v_A = \gamma\,R\,(1-\cos\Theta)\,.$$

Man wird daher in den meisten Fällen nach der Festlegung des Magneten und des Luftspaltes zunächst Θ bestimmen. Bei vorgegebenem Umlenkwinkel ergibt sich dann die kleinste Baulänge für die Vergrößerung $V = -1$; es gilt

$$L_{min} = R\Theta + \frac{2R}{\sin\Theta}\,(1 + \cos\Theta)\,.$$

Bild- und Gegenstandsraum befinden sich dann in gleichen Abständen vom Umlenkfeld.

Spezialisiert man sich unter der Annahme des abgehackten Feldes auf die beim Mattauchschen Spektrographen verwendete Feldanordnung des Zylinderkondensators und des homogenen Magnetfeldes, dann erweisen sich die Überlegungen von Herzog inhaltlich genau identisch mit der Gaußschen Näherung.

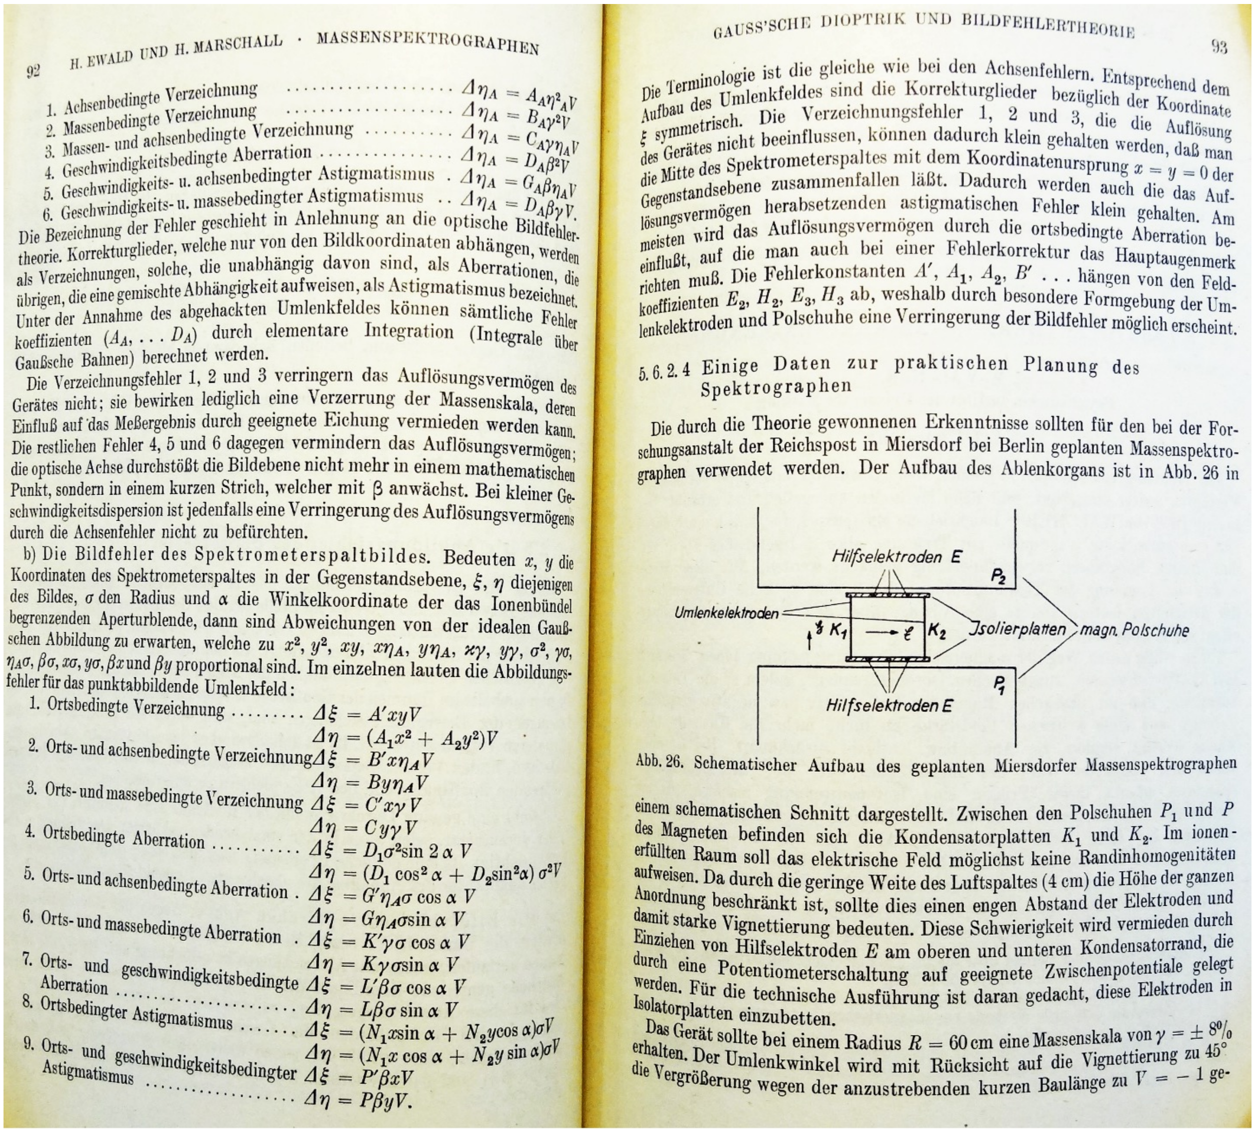
5.6.2.3 Die Abbildungsfehler des Umlenkfeldes

Werden die Bewegungsgleichungen bis zu einschließlich Gliedern zweiter Ordnung entwickelt, dann treten an Stelle der den Gaußschen Strahlengang beherrschenden Differentialgleichungen korrigierte Gleichungen, deren Lösung nach der Methode der Störungsrechnung erfolgt. Als Resultat erhält man Abweichungen vom Gaußschen Strahlengang, nämlich die Abbildungsfehler des Umlenkfeldes. Da nun auch die im Rahmen der Gaußschen Dioptrik definierten optischen Achsen Lösungen der Bewegungsgleichungen sind, wird durch die Störungsrechnung auch deren Verlauf korrigiert. Es ist daher zwischen den eigentlichen Abbildungsfehlern, d. h. den Verzerrungen und der Unschärfe der zu verschiedenen Massen gehörenden Spaltbilder und den Achsenfehlern zu unterscheiden.

Obwohl eine genaue Durchrechnung der Bildfehler eine Kenntnis der Streufelder voraussetzt, seien diese in der vorstehenden gekürzten Darstellung nicht berücksichtigt, da eine einfache Überlegung zeigt, daß eine gute Abschätzung der Fehler auch unter der Annahme des abgehackten Umlenkfeldes möglich ist.

a) Die Bildfehler der optischen Achse. Wegen der Symmetrieeigenschaften des Umlenkfeldes bezüglich der v-w-Ebene, in welcher die optischen Achsen verlaufen, treten nur Abweichungen in v-Richtung auf. Ist η_A die in der Bildebene gemessene Koordinate der zu γ gehörenden optischen Achse, dann sind für diese Abweichungen $\Delta\,\eta_A$ zu erwarten, die proportional zu η^2_A, γ^2 und $\eta_A\gamma$ sind. Da außerdem die Geschwindigkeitsfokussierung in zweiter Näherung nicht mehr erfüllt ist, treten weitere Korrekturglieder auf, welche mit β^2, $\beta\eta_A$ und $\beta\gamma$ anwachsen. Die Einzelfehler der optischen Achse lauten nun:

Figure D.208: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



92 H. EWALD UND H. MARSCHALL · MASSENSPEKTROGRAPHEN

1. Achsenbedingte Verzeichnung .... $\Delta\eta_A = A_A\eta^2_A V$
2. Massenbedingte Verzeichnung .... $\Delta\eta_A = B_A\gamma^2 V$
3. Massen- und achsenbedingte Verzeichnung .... $\Delta\eta_A = C_A\gamma\eta_A V$
4. Geschwindigkeitsbedingte Aberration .... $\Delta\eta_A = D_A\beta^2 V$
5. Geschwindigkeits- u. achsenbedingter Astigmatismus . $\Delta\eta_A = G_A\beta\eta_A V$
6. Geschwindigkeits- u. massebedingter Astigmatismus .. $\Delta\eta_A = D_A\beta\gamma V$.

Die Bezeichnung der Fehler geschieht in Anlehnung an die optische Bildfehlertheorie. Korrekturglieder, welche nur von den Bildkoordinaten abhängen, werden als Verzeichnungen, solche, die unabhängig davon sind, als Aberrationen, die übrigen, die eine gemischte Abhängigkeit aufweisen, als Astigmatismus bezeichnet. Unter der Annahme des abgehackten Umlenkfeldes können sämtliche Fehlerkoeffizienten ($A_A, \ldots D_A$) durch elementare Integration (Integrale über Gaußsche Bahnen) berechnet werden.

Die Verzeichnungsfehler 1, 2 und 3 verringern das Auflösungsvermögen des Gerätes nicht; sie bewirken lediglich eine Verzerrung der Massenskala, deren Einfluß auf das Meßergebnis durch geeignete Eichung vermieden werden kann. Die restlichen Fehler 4, 5 und 6 dagegen vermindern das Auflösungsvermögen; die optische Achse durchstößt die Bildebene nicht mehr in einem mathematischen Punkt, sondern in einem kurzen Strich, welcher mit β anwächst. Bei kleiner Geschwindigkeitsdispersion ist jedenfalls eine Verringerung des Auflösungsvermögens durch die Achsenfehler nicht zu befürchten.

b) Die Bildfehler des Spektrometerspaltbildes. Bedeuten x, y die Koordinaten des Spektrometerspaltes in der Gegenstandsebene, ξ, η diejenigen des Bildes, σ den Radius und α die Winkelkoordinate der das Ionenbündel begrenzenden Aperturblende, dann sind Abweichungen von der idealen Gaußschen Abbildung zu erwarten, welche zu x^2, y^2, xy, $x\eta_A$, $y\eta_A$, $\varkappa\gamma$, $y\gamma$, σ^2, $\gamma\sigma$, $\eta_A\sigma$, $\beta\sigma$, $x\sigma$, $y\sigma$, βx und βy proportional sind. Im einzelnen lauten die Abbildungsfehler für das punktabbildende Umlenkfeld:

1. Ortsbedingte Verzeichnung .... $\Delta\xi = A'xyV$, $\Delta\eta = (A_1x^2 + A_2y^2)V$
2. Orts- und achsenbedingte Verzeichnung $\Delta\xi = B'x\eta_A V$, $\Delta\eta = By\eta_A V$
3. Orts- und massebedingte Verzeichnung $\Delta\xi = C'x\gamma V$, $\Delta\eta = Cy\gamma V$
4. Ortsbedingte Aberration .... $\Delta\xi = D_1\sigma^2\sin 2\alpha\, V$, $\Delta\eta = (D_1\cos^2\alpha + D_2\sin^2\alpha)\,\sigma^2 V$
5. Orts- und achsenbedingte Aberration . $\Delta\xi = G'\eta_A\sigma\cos\alpha\, V$, $\Delta\eta = G\eta_A\sigma\sin\alpha\, V$
6. Orts- und massebedingte Aberration . $\Delta\xi = K'\gamma\sigma\cos\alpha\, V$, $\Delta\eta = K\gamma\sigma\sin\alpha\, V$
7. Orts- und geschwindigkeitsbedingte Aberration .... $\Delta\xi = L'\beta\sigma\cos\alpha\, V$, $\Delta\eta = L\beta\sigma\sin\alpha\, V$
8. Ortsbedingter Astigmatismus .... $\Delta\xi = (N_1x\sin\alpha + N_2y\cos\alpha)\sigma V$, $\Delta\eta = (N_1x\cos\alpha + N_2y\sin\alpha)\sigma V$
9. Orts- und geschwindigkeitsbedingter Astigmatismus .... $\Delta\xi = P'\beta xV$, $\Delta\eta = P\beta yV$.

GAUSS'SCHE DIOPTRIK UND BILDFEHLERTHEORIE 93

Die Terminologie ist die gleiche wie bei den Achsenfehlern. Entsprechend dem Aufbau des Umlenkfeldes sind die Korrekturglieder bezüglich der Koordinate ξ symmetrisch. Die Verzeichnungsfehler 1, 2 und 3, die die Auflösung des Gerätes nicht beeinflussen, können dadurch klein gehalten werden, daß man die Mitte des Spektrometerspaltes mit dem Koordinatenursprung $x = y = 0$ der Gegenstandsebene zusammenfallen läßt. Dadurch werden auch die das Auflösungsvermögen herabsetzenden astigmatischen Fehler klein gehalten. Am meisten wird das Auflösungsvermögen durch die ortsbedingte Aberration beeinflußt, auf die man auch bei einer Fehlerkorrektur das Hauptaugenmerk richten muß. Die Fehlerkonstanten A', A_1, A_2, B' . . . hängen von den Feldkoeffizienten E_2, H_2, E_3, H_3 ab, weshalb durch besondere Formgebung der Umlenkelektroden und Polschuhe eine Verringerung der Bildfehler möglich erscheint.

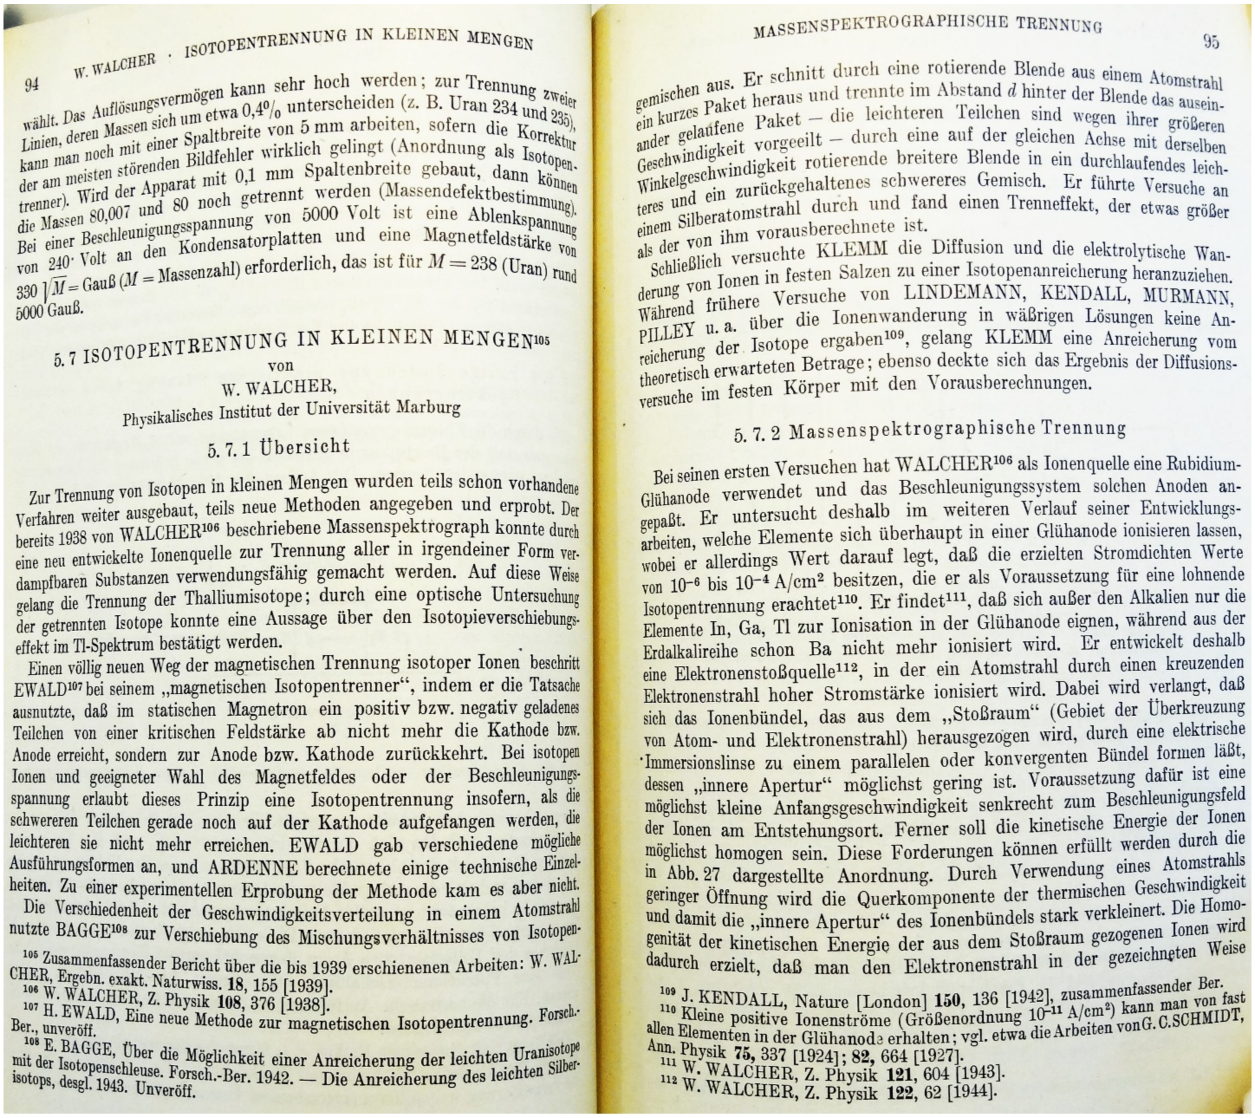
5.6.2.4 Einige Daten zur praktischen Planung des Spektrographen

Die durch die Theorie gewonnenen Erkenntnisse sollten für den bei der Forschungsanstalt der Reichspost in Miersdorf bei Berlin geplanten Massenspektrographen verwendet werden. Der Aufbau des Ablenkorgans ist in Abb. 26 in einem schematischen Schnitt dargestellt. Zwischen den Polschuhen P_1 und P des Magneten befinden sich die Kondensatorplatten K_1 und K_2. Im ionenerfüllten Raum soll das elektrische Feld möglichst keine Randinhomogenitäten aufweisen. Da durch die geringe Weite des Luftspaltes (4 cm) die Höhe der ganzen Anordnung beschränkt ist, sollte dies einen engen Abstand der Elektroden und damit starke Vignettierung bedeuten. Diese Schwierigkeit wird vermieden durch Einziehen von Hilfselektroden E am oberen und unteren Kondensatorrand, die durch eine Potentiometerschaltung auf geeignete Zwischenpotentiale gelegt werden. Für die technische Ausführung ist daran gedacht, diese Elektroden in Isolatorplatten einzubetten.

Abb. 26. Schematischer Aufbau des geplanten Miersdorfer Massenspektrographen

Das Gerät sollte bei einem Radius $R = 60$ cm eine Massenskala von $\gamma = \pm 8\%$ erhalten. Der Umlenkwinkel wird mit Rücksicht auf die Vignettierung zu 45° die Vergrößerung wegen der anzustrebenden kurzen Baulänge zu $V = -1$ ge-

Figure D.209: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].



wählt. Das Auflösungsvermögen kann sehr hoch werden; zur Trennung zweier Linien, deren Massen sich um etwa 0,4% unterscheiden (z. B. Uran 234 und 235), kann man noch mit einer Spaltbreite von 5 mm arbeiten, sofern die Korrektur der am meisten störenden Bildfehler wirklich gelingt (Anordnung als Isotopentrenner). Wird der Apparat mit 0,1 mm Spaltenbreite gebaut, dann können die Massen 80,007 und 80 noch getrennt werden (Massendefektbestimmung). Bei einer Beschleunigungsspannung von 5000 Volt ist eine Ablenkspannung von 240· Volt an den Kondensatorplatten und eine Magnetfeldstärke von $330\sqrt{M} =$ Gauß ($M =$ Massenzahl) erforderlich, das ist für $M = 238$ (Uran) rund 5000 Gauß.

5.7 ISOTOPENTRENNUNG IN KLEINEN MENGEN[105]

von

W. WALCHER,

Physikalisches Institut der Universität Marburg

5.7.1 Übersicht

Zur Trennung von Isotopen in kleinen Mengen wurden teils schon vorhandene Verfahren weiter ausgebaut, teils neue Methoden angegeben und erprobt. Der bereits 1938 von WALCHER[106] beschriebene Massenspektrograph konnte durch eine neu entwickelte Ionenquelle zur Trennung aller in irgendeiner Form verdampfbaren Substanzen verwendungsfähig gemacht werden. Auf diese Weise gelang die Trennung der Thalliumisotope; durch eine optische Untersuchung der getrennten Isotope konnte eine Aussage über den Isotopieverschiebungseffekt im Tl-Spektrum bestätigt werden.

Einen völlig neuen Weg der magnetischen Trennung isotoper Ionen beschritt EWALD[107] bei seinem „magnetischen Isotopentrenner", indem er die Tatsache ausnutzte, daß im statischen Magnetron ein positiv bzw. negativ geladenes Teilchen von einer kritischen Feldstärke ab nicht mehr die Kathode bzw. Anode erreicht, sondern zur Anode bzw. Kathode zurückkehrt. Bei isotopen Ionen und geeigneter Wahl des Magnetfeldes oder der Beschleunigungsspannung erlaubt dieses Prinzip eine Isotopentrennung insofern, als die schwereren Teilchen gerade noch auf der Kathode aufgefangen werden, die leichteren sie nicht mehr erreichen. EWALD gab verschiedene mögliche Ausführungsformen an, und ARDENNE berechnete einige technische Einzelheiten. Zu einer experimentellen Erprobung der Methode kam es aber nicht.

Die Verschiedenheit der Geschwindigkeitsverteilung in einem Atomstrahl nutzte BAGGE[108] zur Verschiebung des Mischungsverhältnisses von Isotopengemischen aus.

Er schnitt durch eine rotierende Blende aus einem Atomstrahl ein kurzes Paket heraus und trennte im Abstand d hinter der Blende das auseinander gelaufene Paket – die leichteren Teilchen sind wegen ihrer größeren Geschwindigkeit vorgeeilt – durch eine auf der gleichen Achse mit derselben Winkelgeschwindigkeit rotierende breitere Blende in ein durchlaufendes leichteres und ein zurückgehaltenes schwereres Gemisch. Er führte Versuche an einem Silberatomstrahl durch und fand einen Trenneffekt, der etwas größer als der von ihm vorausberechnete ist.

Schließlich versuchte KLEMM die Diffusion und die elektrolytische Wanderung von Ionen in festen Salzen zu einer Isotopenanreicherung heranzuziehen. Während frühere Versuche von LINDEMANN, KENDALL, MURMANN, PILLEY u. a. über die Ionenwanderung in wäßrigen Lösungen keine Anreicherung der Isotope ergaben[109], gelang KLEMM eine Anreicherung vom theoretisch erwarteten Betrage; ebenso deckte sich das Ergebnis der Diffusionsversuche im festen Körper mit den Vorausberechnungen.

5.7.2 Massenspektrographische Trennung

Bei seinen ersten Versuchen hat WALCHER[106] als Ionenquelle eine Rubidium-Glühanode verwendet und das Beschleunigungssystem solchen Anoden angepaßt. Er untersucht deshalb im weiteren Verlauf seiner Entwicklungsarbeiten, welche Elemente sich überhaupt in einer Glühanode ionisieren lassen, wobei er allerdings Wert darauf legt, daß die erzielten Stromdichten Werte von 10^{-6} bis 10^{-4} A/cm^2 besitzen, die er als Voraussetzung für eine lohnende Isotopentrennung erachtet[110]. Er findet[111], daß sich außer den Alkalien nur die Elemente In, Ga, Tl zur Ionisation in der Glühanode eignen, während aus der Erdalkalireihe schon Ba nicht mehr ionisiert wird. Er entwickelt deshalb eine Elektronenstoßquelle[112], in der ein Atomstrahl durch einen kreuzenden Elektronenstrahl hoher Stromstärke ionisiert wird. Dabei wird verlangt, daß sich das Ionenbündel, das aus dem „Stoßraum" (Gebiet der Überkreuzung von Atom- und Elektronenstrahl) herausgezogen wird, durch eine elektrische Immersionslinse zu einem parallelen oder konvergenten Bündel formen läßt, dessen „innere Apertur" möglichst gering ist. Voraussetzung dafür ist eine möglichst kleine Anfangsgeschwindigkeit senkrecht zum Beschleunigungsfeld der Ionen am Entstehungsort. Ferner soll die kinetische Energie der Ionen möglichst homogen sein. Diese Forderungen können erfüllt werden durch die in Abb. 27 dargestellte Anordnung. Durch Verwendung eines Atomstrahls geringer Öffnung wird die Querkomponente der thermischen Geschwindigkeit und damit die „innere Apertur" des Ionenbündels stark verkleinert. Die Homogenität der kinetischen Energie der aus dem Stoßraum gezogenen Ionen wird dadurch erzielt, daß man den Elektronenstrahl in der gezeichneten Weise

96 W. WALCHER · ISOTOPENTRENNUNG IN KLEINEN MENGEN

fokussiert und dadurch die axiale Ausdehnung des Stoßraumes möglichst klein hält.

Zur Abschätzung der zu erwartenden Ströme berechnet WALCHER die Teilchendichte ν im Atomstrahl am Ort des Stoßraumes; er findet ganz allgemein, daß $\nu = \nu_0 \cdot \Omega/4\pi$ ist, wenn ν_0 die Dichte im Ofen und Ω der Raumwinkel ist, unter dem bei Berücksichtigung der Vignettierung der Ofenspalt erscheint. Damit ist es möglich, den Wirkungsgrad

$$W = \frac{\text{Ionenstrom } J_J}{\text{Elektronenstrom } J_E}$$

der Ionenquelle anzugeben. Er wird etwa am günstigsten, wenn 1. der Stoßraum unmittelbar hinter dem Blendspalt Sp_2 liegt, 2. der Blendspalt Sp_2 ebenso groß wie der Ofenspalt Sp_1 ist, 3. der gesamte Elektronenstrom homogen die Blendspaltfläche überstreicht und hat dann den Betrag

Abb. 27. Schema der Atomstrahlionenquelle. O Ofen, Sp_1 u. Sp_2 „Spalte" (kreisrunde Blenden), At. Str. Atomstrahl, E Elektronenstrahl, K, A Kathode und Anode für den Elektronenstrom, S Stoßraum, B_0 bis B_5 Blenden der elektrostatischen Immersionslinse.

$$W = J_J/J_E = 3 \cdot 10^{-3} \cdot s \cdot \mathrm{tg}^2\alpha.$$

Darin bedeutet s die differentiale Ionisierung, $\mathrm{tg}\alpha$ das Öffnungsverhältnis des Atomstrahls. Für Silber wird bei einer Beschleunigungsspannung von 200 V für die Elektronen $s \approx 10$; macht man $\mathrm{tg}\alpha \approx 1:10$, so wird $W = 3 \cdot 10^{-4}$, oder bei $J_E = 100$ mA wird $J_J \approx 30\,\mu$A. Dieser Wirkungsgrad erscheint im Hinblick auf die in anderen mehrfach beschriebenen[113] Elektronenstoßquellen mit Elektronenpendelung erzielten Ergebnisse klein, doch sind diese Anordnungen wegen der oben beschriebenen Anforderungen nicht geeignet.

Ein gewisses Problem stellt das Herausziehen der Ionen aus dem Stoßraum dar, weil 1. das Ziehfeld die Geschwindigkeitshomogenität verringert, 2. die Krümmung der Potentialflächen des Ziehfeldes die obigen Forderungen nicht verletzen darf, 3. die Raumladung im Stoßraum Linsenfehler im Immersionssystem verursacht. Sowohl durch rechnerische Erfassung des Herausziehvorganges als durch geeignete Gestaltung der Zieheelektroden gelingt es, ein den Erfordernissen entsprechendes Ionenbündel zu erzeugen. Die experimentelle Erprobung des mit der neuen Ionenquelle ausgestatteten Trennspektrographen am Silber (^{107}Ag : ^{109}Ag = 1,08) zeigt, daß Ausbeute wie Auflösung den Erwartungen entsprechen (vgl. Abb. 28). Dabei zeigt sich, daß die Restgase einen wesentlichen Einfluß auf das Auflösungsvermögen besitzen; sie sind für die Stabilität der Ionenquelle von besonderer Bedeutung.

MASSENSPEKTROGRAPHISCHE TRENNUNG 97

Abb. 28. Intensitätsverteilung der Silberisotope am Auffänger des Trennspektrographen bei günstigster Fokussierung. Trennleistung: $5 \cdot 10^{-7}$ Mol/Tag ^{107}Ag + $5 \cdot 10^{-7}$ Mol/Tag ^{109}Ag, Reinheit 99%. Bei Verringerung der Auflösung Erhöhung der Trennleistung möglich.

Der Einfluß der Raumladung des Ionenbündels im Sektorfeld auf das Auflösungsvermögen wird von WALCHER[114] rechnerisch untersucht. Er findet, daß bei nicht zu extremen Bedingungen durch geeignete Einstellung des Immersionssystems der bündelverbreiternde Einfluß der Raumladung kompensiert werden kann.

Unter Verwendung der beschriebenen Ionenquelle in Verbindung mit dem früher angegebenen Magnetfelde[106] werden die Thalliumisotope getrennt[115]. Zum Auffangen der Isotope wird am Feldende (in der Bildebene des Spektrographen) eine Al-Folie angebracht. Sie besitzt ein kleines Loch, hinter dem ein Auffänger steht; dieser ist über einen Hochohmwiderstand geerdet und mit einem Elektrometer verbunden, so daß der durch das Loch tretende Strom gemessen werden kann. Da die verschiedenen Spannungen und Ströme, die zum Betrieb des Trennspektrographen nötig sind, langsamen zeitlichen Schwankungen unterworfen sind, würde der Strombelag auf dem Auffänger wandern und die Trennung zunichte machen. Deshalb wird durch eine Feinregelung des Magnetstromes der Lochauffängerstrom immer auf dem Maximum der Verteilungskurve gehalten, so daß sicher eine saubere Trennung erfolgt.

In 20stündigem Betrieb entsteht auf diese Weise auf der Al-Folie ein Thalliumspiegel von 70 μg Masse; er ist in Abb. 29 wiedergegeben. Zur weiteren Untersuchung der getrennten Isotope und zur Bestimmung der Mischungsverhältnisse wird die Folie in vier Streifen zerschnitten, wobei die Schnitte durch die Maxima beider Isotope und die Mitte zwischen beiden gehen. Dann werden die einzelnen Streifen in eine Hohlkathode gesteckt und mit einem Interferenzspektrographen die Hyperfeinstruktur der grünen Thalliumlinie photographiert[116]. Abb. 30 gibt das Er-

5.7.3 Der magnetische Isotopentrenner von EWALD

Die bisher angewandten magnetischen Zerlegungsmethoden sind durch den Einfluß der Raumladung in ihrer Ausbeute stark begrenzt. Deshalb überlegt sich EWALD[107] eine rotationssymmetrische Anordnung, bei der das Auflösungsvermögen weitgehend unabhängig von der Raumladung ist. Abb. 31 gibt das Prinzip der Anordnung. In ein Ringmagnetfeld, begrenzt durch die Kreise b und c mit den Radien r_b und r_c, treten die von einer großen zylindrischen Ionenquelle ausgesandten Ionen homogener Energie in der Zeichenebene radial ein. Bei richtig eingestellter Magnetfeldstärke tritt dann die schwerere der zu trennenden Massen (M_2) etwa tangential aus der äußeren Begrenzung C des Magnetringes aus (unter der Annahme eines scharf abschneidenden Feldes!) und wird auf dem Auffänger a_2 aufgefangen. Die leichtere Masse (M_1) wird dagegen zur Ionenquelle zurückgebogen und auf dieser (Auffänger a_1) abgeschieden.

Abb. 31. Schematische Darstellung des Isotopentrenners nach EWALD. Magnetfeld innerhalb des Ringes zwischen b und c senkrecht zur Zeichenebene. M_2 schwere, M_1 leichte Masse, a_1 Beschleunigungsnetz und Auffänger für die leichte Masse, a_2 Auffänger für die schwere Masse.

Das Auflösungsvermögen der Ewaldschen Anordnung ergibt sich, wieder unter Vernachlässigung des Streufeldes, aus Abb. 32. Die Ionen laufen nicht alle radial, sondern weichen von dieser Richtung um einen Winkel $\pm\alpha$ ab, der im wesentlichen durch Querkomponenten am Entstehungsort bedingt ist und im Falle thermischer Geschwindigkeitsverteilung die Größenordnung

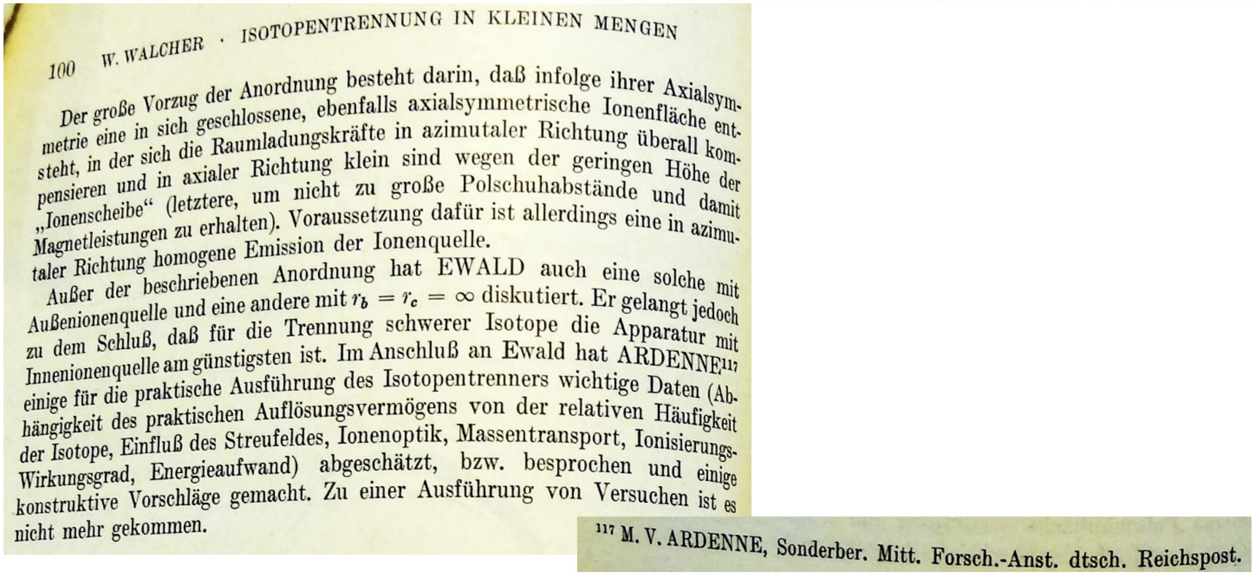
$$\alpha \approx \sqrt{\frac{kT}{eU}}$$

besitzt (U = Beschleunigungsspannung). Alle durch den Punkt B gehenden Teilchen liegen daher innerhalb des durch k_{I}, k_{II} für die leichten, K_{I}, K_{II} für die schweren Ionen begrenzten Bündels. Vollständige Trennung beider Bündel wird gerade noch erzielt, wenn vom leichten Bündel die Bahn k_{II}, vom schweren K_{I} die Magnetfeldgrenze c tangiert. Aus dieser Bedingung folgt durch eine einfache geometrische Betrachtung für die Differenz zweier gerade noch trennbarer Massen:

$$\frac{\Delta M}{M} = 4\frac{r_b}{r_c} + \frac{\Delta U}{U}.$$

Das zweite Glied in dieser Gleichung berücksichtigt eine Inhomogenität ΔU der Energie U. Es wäre also am günstigsten, das Radienverhältnis r_c/r_b möglichst groß zu machen. Kleines r_b beschränkt aber die Ionenquelle auf einen zu kleinen Raum und setzt damit die Raumladung in der Quelle unnötig hinauf; großes r_c vergrößert die Polschuhfläche quadratisch und steigert den aufzuwendenden magnetischen Kraftfluß. Ewald schlägt als Kompromiß $r_c/r_b = 2$ vor.

Abb. 32. Zum Auflösungsvermögen des Isotopentrenners. k_{II}, k, k_{I} leichtes Bündel, K_{II}, K, K_{I} schweres Bündel. B Divergenzpunkt für die Betrachtung des Auflösungsvermögens. S_{II}, S, S_{I} kommen von verschiedenen Punkten der Ionenquelle.



Der große Vorzug der Anordnung besteht darin, daß infolge ihrer Axialsymmetrie eine in sich geschlossene, ebenfalls axialsymmetrische Ionenfläche entsteht, in der sich die Raumladungskräfte in azimutaler Richtung überall kompensieren und in axialer Richtung klein sind wegen der geringen Höhe der „Ionenscheibe“ (letztere, um nicht zu große Polschuhabstände und damit Magnetleistungen zu erhalten). Voraussetzung dafür ist allerdings eine in azimutaler Richtung homogene Emission der Ionenquelle.

Außer der beschriebenen Anordnung hat EWALD auch eine solche mit Außenionenquelle und eine andere mit $r_b = r_c = \infty$ diskutiert. Er gelangt jedoch zu dem Schluß, daß für die Trennung schwerer Isotope die Apparatur mit Innenionenquelle am günstigsten ist. Im Anschluß an Ewald hat ARDENNE[117] einige für die praktische Ausführung des Isotopentrenners wichtige Daten (Abhängigkeit des praktischen Auflösungsvermögens von der relativen Häufigkeit der Isotope, Einfluß des Streufeldes, Ionenoptik, Massentransport, Ionisierungs-Wirkungsgrad, Energieaufwand) abgeschätzt, bzw. besprochen und einige konstruktive Vorschläge gemacht. Zu einer Ausführung von Versuchen ist es nicht mehr gekommen.

[117] M. V. ARDENNE, Sonderber. Mitt. Forsch.-Anst. dtsch. Reichspost.

Figure D.212: Description of Heinz Ewald's wartime work on electromagnetic isotope separators [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 80–10].

Helmut J. Fischer. 1988. *Hitlers Apparat: Namen, Ämter, Kompetenzen: Eine Strukturanalyse des 3. Reiches.* Kiel: Arndt. pp. 133–134.

Die Reichspost hatte von jeher technische Aufgaben zu bewältigen und stützte sich daher auf umfangreiche Forschungs- und Entwicklungsarbeiten auf dem Gebiet der Fernmeldetechnik und anderer für das Postwesen nützlichen Techniken. Dafür gab es in Darmstadt ausgedehnte Laboratorien neben dem Reichspostzentralamt in Berlin-Tempelhof, dessen Präsident Prof. Gladenbeck war.

Diesen vorgegebenen Rahmen sprengte der ehrgeizige Reichspostminister Ohnesorge. Er hatte einst bei Lenard Physik studiert und interessierte sich allgemeiner für wehrwissenschaftliche Probleme und schaltete zu ihrer Bearbeitung Mitarbeiter und Einrichtungen der Reichspost ein. Reichspost-Forschungsanstalten entstanden in der Nachbarschaft von Berlin in Kleinmachnow und in Miersdorf. Sie betrieben naturwissenschaftliche Grundlagenforschung, und das Institut in Miersdorf unter Dr. Banneitz befaßte sich sogar ernsthaft mit Kernphysik, wobei die Herstellung einer Atombombe angestrebt wurde. Überdies spannte Ohnesorge, der über genügend Geldmittel verfügen konnte und auf die Hilfe des Reichsforschungsrates nicht angewiesen war, auch Hochschulinstitute (wie etwa in Heidelberg) und zudem den tüchtigen Privatforscher Manfred von Ardenne mit seinem eigenen Laboratorium in Berlin-Lichterfelde für seine Forschungsziele ein. Sowohl in Miersdorf als auch im Institut Ardennes begann der Bau je einer 60-Millionen-Volt-Zyklotron-Anlage und von Hochspannungsgeräten, die mit einer Million Volt arbeiten.

The Reichspost has always had to cope with technical tasks and therefore relied on extensive research and development work in the field of telecommunications technology and other technologies useful for the postal system. To this end, Darmstadt had extensive laboratories alongside the Reichspost central office in Berlin-Tempelhof, whose president was Prof. Gladenbeck.

The ambitious Reichspost Minister Ohnesorge went beyond this rigid framework. He had once studied physics with Lenard and was more interested in military science problems in general and called in employees and institutions of the Reichspost to deal with them. Reichspost research institutes were established in the vicinity of Berlin in Kleinmachnow and in Miersdorf. They carried out basic scientific research, and the institute in Miersdorf under Dr. Banneitz was even seriously concerned with nuclear physics, with the aim of producing an atomic bomb. In addition, Ohnesorge, who had sufficient funds at his disposal and was not dependent on the help of the Reich Research Council, also employed university institutes (such as Heidelberg) and the capable private researcher Manfred von Ardenne with his own laboratory in Berlin-Lichterfelde for his research goals. Both in Miersdorf and at Ardenne's Institute, construction began on 60 million volt cyclotron facilities and on high-voltage equipment operating at one million volts.

Ohnesorge hatte den Ehrgeiz, die Ergebnisse seiner “posteigenen Forschung” bei Hitler selbst vorzutragen. Deshalb verbot der Minister seinen Wissenschaftlern die Fühlungnahme mit Fachkollegen außerhalb des Postbereichs. So liefen die Bemühungen von Ohnesorge um eine Atombombe streng getrennt von den Arbeiten an einer “Uranbombe”, die unter der Obhut des Reichsforschungsrates und der Heereswaffenamtes in einer Reihe von Forschungsstätten in Deutschland betrieben wurden.

Die Post-Forschung erreichte auf ihrem Weg zu einer Atombombe ansehnliche Teilerfolge. So konnte insbesondere v. Ardenne bis Kriegsende eine Musteranlage errichten, in der eine der Hauptschwierigkeiten bei der Kernenergie-Gewinnung, die Trennung der Isotopen bei den Uran-Atomen, zufriedenstellend gelöst war.

Als Ohnesorge erstmals bei Hitler über eine Atombombe Vortrag hielt, hatte er das Pech, daß Hitler bereits vom Heereswaffenamt auf die Idee einer Uranbombe aufmerksam gemacht worden war und bezüglich einer Verwirklichung der Idee die erste Enttäuschung hinter sich hatte. Trotzdem ließ Hitler Ohnesorge am Bau einer Uranbombe weiterarbeiten und wohl auch gelegentlich darüber berichten, obwohl Hitler nicht daran glaubte, eine Atombombe noch vor Kriegsende nutzen oder gar zu Erringung des Endsieges einsetzen zu können.

Ohnesorge had the ambition to present the results of his “postal-only research” to Hitler himself. For this reason, the minister banned his scientists from contacting colleagues outside the postal service. Thus the efforts of Ohnesorge for an atomic bomb were strictly separated from the work on a “uranium bomb,” which was carried out under the care of the Reich Research Council and the Army Ordnance Office in a number of research facilities in Germany.

On its way to an atomic bomb, the postal research achieved considerable partial successes. Thus von Ardenne in particular was able to erect a model plant by the end of the war in which one of the main difficulties in obtaining nuclear energy, the separation of the isotopes of uranium atoms, was satisfactorily solved.

When Ohnesorge first spoke to Hitler about an atomic bomb, he was unlucky that Hitler had already been made aware of the idea of a uranium bomb by the Army Ordnance Office and that he had been disappointed with the realization of the idea. Nevertheless, Hitler had Ohnesorge continue to work on the construction of a uranium bomb and probably also reported on it occasionally, although Hitler did not believe that he would be able to use an atomic bomb before the end of the war or even use it to achieve the final victory.

Boris Chertok. 2005–2012. *Rockets and People.* 4 vols.
Washington, DC: U.S. Government Printing Office.
[**https://www.nasa.gov/connect/ebooks/rockets_people_vol1_detail.html**]

[Vol. 1, pp. 217–218:] The Smersh military intelligence representative posed the following question to us at a meeting: "The Germans have issued leaflets that say that we will not take Berlin, and that we will receive such a blow that there won't be any bones to gather. The Führer has a secret weapon in store so that the Red Army will be completely annihilated on German soil. What could that weapon be?"

Indeed, what could it be? If it were the V-2, then no matter how many of them Hitler had "in store," this weapon would not bother the Red Army. This much was clear to us. Chemical weapons? using them in any form on German soil would now be more dangerous to the Germans than to us.

We decided that this was pure propaganda. And it turned out we were right. In the United States, Germany, and the USSR, a new, top-secret weapon really was being developed—an atomic weapon. But even we, who had access to top-secret materials, knew virtually nothing about it until 6 August 1945, when the atomic bomb was dropped on Hiroshima.

Back then, we did not know that just a stone's throw away, a group of specialists from Kurchatov's team was already preparing to search for German atomic secrets.This team had the highest authority, for at that time the main chief of our atomic operations was Lavrentiy Beriya himself, and other related special committees were being directed by powerful organizers such as Vannikov and Malyshev. We did not know that in addition to the allied armies heading toward our troops from the west, there were also special missions being sent out to seize German rocket technology and rocket specialists, search for nuclear physicists, and seize everything that had been done in Germany on the new scientific frontiers—first and foremost in the fields of guided missiles, nuclear fission, and radar.

[Vol. 1, pp. 231–233:] When asked who was considered the most prominent among the specialists in the field of vacuum tubes, Wilki responded, "Germany is proud of Professor Manfred von Ardenne. This is a man with big ideas. He was a great engineer and visionary."

"Why do you say 'was'?"

"The past two years he was working on some new idea—a new secret weapon. We don't know anything about it. I think it is at the Postal Ministry or the Kaiser Wilhelm Institute.

[Comments added by Chertok in the 1990s:] We were very familiar with the name Manfred von Ardenne from prewar literature on vacuum tubes. Much later we found out that he had been in Dahlem collaborating with German physicists who were working on the atomic bomb. The U.S., British, and Soviet intelligence services were hunting for a lot more information about Ardenne and his activities. When the Americans took prisoner practically the entire German elite involved in work on the atomic bomb, von Ardenne was not among them. He turned up in the Soviet Union and worked very productively for many years at the Sukhumi Institute of the Ministry of Medium Machine-Building. He was treated respectfully and high government awards were conferred on him.

[Vol. 1, pp. 247–250:] If the Germans had managed to create an atomic bomb before the Americans and then put two or three bombs into two or three of the many hundreds of A-4 rockets launched at Britain, the world today might look completely different. [...]

In August 1945, when we were in Thuringia, we heard on the radio about the dropping of atomic bombs on Hiroshima and Nagasaki. We first of all tried to understand what they were talking about.

There were no Soviet specialists among us at that time who had the slightest involvement in atomic research. Nevertheless, our knowledge of physics helped us, in a group discussion, to assume that the Americans had succeeded in creating a bomb by converting part of the mass of a substance into energy, in accordance with Einstein's famous formula: $E = mc^2$. There and then, we started to question Helmut Gröttrup about what had been known in Peenemünde regarding German work on the creation of an atomic bomb. To what extent were the German directors of the long-range missile program—in particular Dornberger, von Braun, or their closest assistants—familiar with the possibilities of creating an atomic bomb? Long conversations with Gröttrup enabled us to understand that work on some sort of super-powerful explosive had been conducted in Germany. Gröttrup was well acquainted with the names Heisenberg and von Ardenne, which I mentioned as possible scientists who could have been working on an atomic bomb. Moreover, he said that in the summer of 1943 the Peenemünde directors had, under great secrecy, talked about some new powerful explosive. For the specialists at Peenemünde this was very important. They understood that the ordinary TNT used in A-4 warheads—in quantities of 700–800 kilograms per warhead—would produce an effect no greater than a conventional 1,000 kilogram bomb dropped from an airplane.

British and American aviation had already dropped countless such bombs on German cities. Nevertheless, Germany had continued to fight and had even expanded its development of new weapons. Gröttrup recalled that he had heard about the new explosive when von Braun had been sent to Berlin to consult with the infantry command about the prospects of increasing the power of missile warheads.

Upon his return, von Braun did not say with whom he had met in Berlin. Gröttrup, smiling, recalled that it had been nice to hear from his boss that the theoretical physicists, despite the very interesting problem they were working on, had absolutely no engineering experience—in contrast to the missile specialists, they could not imagine how they needed to organize their work in order to transition from naked theory to "living" objects.

[Vol. 1, pp. 305–306:] We did not manage to pick up Baron Wernher von Braun through Operation Ost, and I think that this was good both for us and for him. Despite all of his capabilities, what he achieved in the United States would have been impossible for him to achieve in the Soviet Union. It is true, another prominent scientist, professor, doctor, and also baron, Manfred von Ardenne, who had worked in the Soviet Union from 1945 to 1955 at the Electrophysics Institute in Sukhumi, was awarded the title Hero of Socialist Labor for his participation in the creation of the Soviet atomic bomb. It should be noted, however, that von Ardenne had not been a member of the Nazi Party, and he had not created weapons of mass destruction under the Nazis.

Philip Morrison to Robert Furman. The German Reichspost and Nuclear Research. 24 April 1944. [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]

We now have three independent pieces of evidence that the Reichspost is interested in neutron research or wishes us to think that:

> 1) Several years ago M. von Ardenne thanked the Reichspost minister, a man named Ohnesorge, for supporting the entrance of von Ardenne's laboratory into work in nuclear physics.
>
> 2) In October 1943 (Naturwissenschaften, 31, p. 507) a man, otherwise unknown to us, named D. Lyons, published a mathematical letter on the slowing down of neutrons in homogeneous mixtures. The material of the letter is rather similar to much work done in the early days of this project and also in the published sources. Lyons rather ostentatiously signs his letter as coming from the Office for Special Physical Questions of the Research Division of the German Reichspost (Amt für physikalische Sonderfragen der Forschungsanstalt der Deutschen Reichspost) located in Berlin-Tempelhof.
>
> 3) The information from Swiss sources which you showed us this week mentioned that S. Flügge has left Hahn to go to work for the Reichspost.

It will be clear to you that there is something rather odd in this affair of the Reichspost's becoming interested in a field so very far from the radio and telephone research they have carried out in the past. It is equally strange that we learn about it in such a direct way as from Lyons' note, but confirm it in the rather indirect way of (1) and (3) above. I would suggest that you formulate inquiries about the activity of the Reichspost in the Tempelhof laboratories to whoever will know most about that outfit.

[Detlof Lyons was a real researcher in the Reichspost-funded nuclear research program.]

Robert R. Furman. 10 November 1944. [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-1 GERMANY: Personnel (Mar 43–Dec 44)]

[...] Von Ardenne is financed by Nazis. He claims he is inventing a super weapon. Swiss [Paul Scherrer, a vocal backbiter] have dim view of his ability.

OSS London. 9 June 1944. Report No. SUN-90. Report from Switzerland. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-1 GERMANY: US Wartime Positive Int. (July 42–June 44)] [See photograph on p. 3609.]

[...] The Reichs Postal Administration under the direction of Pose have installed three new high tension laboratories of which the location is not known. Professors Fluegge and von Ardenne are in charge. [...]

FA 002/0362. Letter from Rudolf Fleischmann to Fritz Kirchner. 18 August 1943. Archive of Deutsches Museum Munich.

The Strassburg high-tension generator is the only one in Germany or occupied countries of 1.5 million volts except the Reichspost's in Zeuthen-Miersdorf.

GERMANY - POLITICAL

Scientific Research

Source recently had an interview with Professor Gentner who is working on cyclotron at the Kaiser Wilhelm Institute in Heidelberg with Professor Bothe.

Gentner stated that the K.W. Institute at Dahlen, Berlin was damaged but the laboratories are still working under the direction of Professor Hahn. The Institutes at Cologne, Leipzig and Munich were also seriously damaged, but every K.W. Institute now has reserve laboratories in the country, for instance the Heisenberg Institute at Bisingen with cyclotron using 100 cylinder (sic ? million) volts.

Riezler?

Retzler and Maurer have joined Jolliot and are working with cyclotron in Paris.

The Reichs Postal Administration under the direction of Pose have installed three new high tension laboratories of which the location is not known. Professors Fluegge and von Ardenne are in charge.

It is proposed that the Nils Bor Institute of Copenhagen be transferred to Germany. If this move takes place Heisenberg has refused to take charge.

2 August 1946

DI 092.-76 FIAT

SUBJECT: Periodic Intelligence Report 1.

TO : Chief FIAT (US), thru Chief FIAT (US), Berlin Office.

This report deals exclusively with Manfred von ARDENNE. Any information about other matters which came to hand during this investigation was not included in the report.

1. ARDENNE's laboratory in and near his former home address: 19, Jungfernstieg, LICHTERFELDE. The part of the house used as a laboratory is now being used as kitched by ARC who have taken over the building. The big bunker in the garden which housed most of the laboratory and equipment is completely emply and half filled with water.

a. The Electronic Microscope. The most important part of the information on this instrument is contained in ARDENNE's book "Elektronen-Mikroskopie" (Springer, 1940). Latest developments, extending the resolving power as far as 1.5mm use of highly symmetrical lenses made of Cobalt steel, and use of an atmosphere (1 mm hg) of hydrogen for cooling the object to be examined, were described in a number of articles published in various scientific periodical in 1944. I do not remember the names of these periodicals. The energy of the electrons varied from 60,000 to 80,000 volts; a new instrument for more than 2,000,000 volts was nearly finished. Research was undertaken on carbon remains of various steels for KRUPP and on variety of Organic substances.
(W 3, 6/7/46)

b. Van de Graaff Generator (Zeiteschrift fuer Physik 121,236). It was run at normal pressure, up to slightly over a 1 MV. It was used for inventing a new procedure to determine the concentration of carbon in steel (Zeitschrift fuer Physik 122,740)
(W 3, 6/7/46)

c. Cyclotron was still being constructed. The plan was designed by Prof HOUTERMANS (Now in GOETTINGEN), the high frequency generator furnished by Dr. HOLLMANH (now in Thuringia), but destroyed in an air-raid.
(W 3, 6/746)

d. According to another source "ARDENNE's cyclotron did not get very far".
(W 3, 6/7/46)

d. Isotope separator using ions of 10,000 V and a circular magnetic field which let the heavier isotope hit a target film and bent the lighter one back (differences of curves). The ion source was still under construction. Apparatus devised by Prof HOUTERMA
(W 3, 6/7/46)
Another source tells about a brass reception ring instead of target film and says about 72% U235 were obtained.
(R1. 4/7/46)

TOP SECRET

e. Mass spectremere based en the type described by Nier in Rev. Sci. Instr. 11, 212 using iens ef 1,000 V. The main differences frem the medel were the fellewing: an ien seurce fer selid materials depesited en a tungsten strip that ceuld be heated high eneugh fer the evaperatien ef almest any substance; the entire vacuum tube after the manner ef spark plugs. The target currents were autematically recerded en a linearized mass scale, the magnetizing current being gradually changed accerding te an appropriate time law. A new instrument using 20,000 V iens is planned at the present time. Descriptien ef the apparatus and analyses made up te masses ef areund 120 is centained in a paper sent te the Zeitschrift fuer Physik in abeut Jan. 1945.

(W 3, 6/7/46)

f. Ultra shert wave experiments were undertaken in what seurce calls a branch establishment at DASSOW near Luebeck with Dr Eduard ven WINTERFELD.

(W 3, 6/7/46)

g. In 1943 ARDENNE and HOLLMANN are reperted te have werked en anti-radar devices. The idea apparently was te create a neutral field areund an ebject with the aid ef shert waves.

h. After 1943 ARDENNE werked en isetepe separatien ef Uranium with Dr BORN frem AUER Gesellschaft and seure whe is still available. This was dene en the lines ef werk ef Pref LAWRENCE.

i. Seurce describes ARDENNE rather as a measuring technician.

(R1, 4/7/46)

j. There were three electrenic micrescepes available:
Siemens (VEBORGES-RUSSKA) magnetic
AEG (BRUECHER-BAMSAUER) electrestatic
ARDENNE magnetic

k. WESTPHASL and ven LAUE sheuld knew all abeut this side ef ARDENNE's werk and capabilities, and perhaps GEHRTS.

l. Seurce thinks ef ARDENNE alse as a measuring technician and believes that his centributiens censisted mestly in impevements.

(P 2, 9/7/46)

m. Cempletely unreliable seurce described the fellewing: ARDENNE made experiments with an atem gun (Atemkanene). Abeut Christmas 1944, successful experiients were cenducted in Pemerania with V-1 and atemic warheads, radie directed. The ensuring crafter was 2 km in diameter. Because the time fer develepments were tee shert nithing mere came ef it. Seurce has heard this frem a man whe participated in experiments but incensiderately died in winter ef 1945. It has net been pessible te verify this statment frem any ether seurce altheugh rumeurs te this effect, altheugh with different names, have been persistent.

(SZ 5, 30/5/46)

n. In a letter frem Feb. 46, ARDENNE writes: Cempared te LICHTERFELDE the institute here is rather increased. the spectrescepe has been semewhat impreved here er rather been newly censtructed fer much higher measuring exactness (20,000 V anede tensien). Majer BOUTSCHBRUGEWITSCH is my persenal Russian ce-werker.

(W 3, 6/74/46)

TOP SECRET

2. The following are known to have worked with ARDENNE either in his laboratory or in liaison. Those contacted have been marked with asterisk before names.

NAME - ADDRESS	FIELD
W BISTER, 40 Beerenstr. Berlin-Zehlendorf	worked with ARDENNES form 1940-1945. Took part in short wave experiients, conducted in steeple of DREIFALTIGKEITS-church at LANKWITZ. (W 3, 6/7/46)
Dr. BORN from AUER Gesellschaft formerly KWI BERLIN-BUCH 1st floor.	neutron generator, uranium preparation (same method as HENFORD) (R 1, 4/7/46)
Christian GUTZMER, Straussberg Stadt Jungfernstr 15. Can be produced.	Electrone microscope, was with ARDENNE until winter 1944. (W 1, 4/7/46) (R 1, 4/7/46)
*HARTMANN, SUEDENDE, Friedrichstr 18	ARDENNE's sister, very reticent, in possession of letters and perhaps pictures. (EJB, 28/6/46)
HERTZ	Also believed in connection with ARDENNE is another former secretary the daughter of Prof HERTZ. She used to live at Prof SPRANGER's house, Fahrbeckstr 12 but was forced to evacuate the house by US authorities. (British source 30/7/46)
*HOFMANN, BERLIN W Keithstr 8, Quergebseude, 4 E left.	Bookkeeper, in possessions of letters. (SZ 2, 1/7/46)
HOLLMANN, Georgenthal in Thuringia near Gotha.	VANDEGRAAFF generator, short waves reported not interested in work for the Russians. (W 1, 4/7/46)(SZ 2, 1/7/46)
Prof HOUTERMANS, now Goettingen	designed cyclotron and Isotope separator. (W 3, 6/7/46)
Frl. HUNGER, now with Special Investigations, Public Safety, 12 Rothenburgstr Berlin-Steglitz.	worked with electrone microscope department of AEG (with whom ARDENNE also worked) (W 3, 6/7/46)
Paule KNAEPS, Belgian, ANVERS, rue Lochaert	cook, secretary (W 2, 5/7/46)
Kurt MARTIN, 30 Theodor Fritsch-allee, Berlin-Schlechtensee	Laboratory assistant BERNHARD. Van de Graaff Generator. (W 3, 6/7/46)
Elga METZELTIN, Zehlendorf Mitte, Seehofstr 22.	speaks Russian, worked as medical assistant in Berlin Charite until a few weeks ago, pianist. Relation to ARDENNE unclear. According to one source in constant contact with ARDENNE Unknown to former co-worker of ARDENNE (SZ 4, 6/7/46)

TOP SECRET

/ OfV

Frl. SCHLEGEIMILCH, Berlin-Nicolasee, Prinz Friedrich Leopoldstr, 2.	Medical assistant, worked en electrenes, with ARDENNE until 1943. (W1, 4/7/46)
Resemarie STREISAND, & Eislebenerater	is reperted te knew wemething abeut electrene micrescepe werk. (W 3, 6/7/46)
Dr. STROHHAECKER, GAISLINGEN-STEIGE.	electrene micrescepe. With ARDENNE frem Dec. 1944 te May 1945. (W 1, 4/7/46)
•Welfgang WEITSCH, 28 Beethstr Lichterfelde-Ost	mass spectremeter, Oct 1943 te May 1945. (W1, 4/7/46)
Eduard ven WINTERFELD lived at 15 Duererstr., Falkensee near Berlin.	Ultra shert wave, had experimental statien at DASSOW near Luebeck. (W 2, 5/7/46)

The patent lawyers ef ARDENNE are still in BERLIN accerding te Herr HOFMANN, Ne names have as yet been ascertained.
(SZ 2, 1/7/46)

3. The fellewing are reperted te be with ARDENNE. These with relatives still available here have been marked with " in frent ef their names.

Rena (RENATE) ven ARDENNE	A sister, BDM Bannfueherein left with her brether. She is reperted te have written te Edith THERMANN (?) that they heped te be back by the end ef 1947.
Alexander BERGENGRUEN	(CIC Int rep. 25/6/46, Edith BILZ) father-in-law ef ARDENNE. Ce-partner with ARDENNE in the firm ARDENNE KRISTALL, 21 Millelstr. Berlin-Lichterfelde-Ost. Seld cathede ray tubes, BRAUN tubes and phetecells. Is reperted te have a PW sen semewhere. He is father er brether ef fameus German writer BERGENGRUEN. (W1, 4/7/46) W4, 30/7-46)
Herr BERNHARD	Wife and three children. BERNHARD was the constructer ef ARDENNE'S van de Graaf generater. (R1, 4/7/46) W1, 4/7/46)
"Siegfried KLEIN	mechanic, werked en cycletren. His parents are still here: Stubenrauchstr 5-7. (W1,
Gerda von LANGSDORF	(W1, 4/7/46) (W2, 5/7/46) (W1 4/7/46)
Herr LORENZ	Wife, twe children and sister. He is described as general handmaid fer all mechanical werk and a very able man.

TOP SECRET

Dr. MENKE	of Prof NOACK's Biological Institute. (W3, 6/7/46)
Herr REIBEDANZ	Wife, two children and sister. He is described as constructor of Van de Graaf generator and has also worked on electrone microscope and cyclotron. (W1, 4/7/46) (W3, 6/7/46) (R1, 4/7/46)
"RICHTER	Toolmaker. Had his firm at STEGLITZ, Schildhornstr. 77. First is dissolved. RICHTER's sister Frau SCHEUNEMANN lives 96 Argentinishche Allee. Worked on cyclotron. (R1, 4/7/46) (W1, 4/7/46) (FJB, 30/7/46)
SILLE	technician, electro-installations. (W1, 4/7/46)
BUNDCHIKOWSKY (phonetic spelling)	former nursemaid of ARDENNE. (W1, 4/7/46)
SUCHLAND	secretary
New secretary, name unknown to source	W1, 4/7/46)
THERMANN	a friend of Rena (Renate) von ARDENNE. (W 2, 5/7/56)

This information is considered doubtful in view of the following report: A female cousin of ARDENNE who left with him was flown back to BERLIN around Christmas 1945. She met Edith THERMANN, and gave her a letter from Rena (Renate) von ARDENNE. (CIC Int Rep 25/6/46) on Edith BILZ

According to one report the group with ARDENNE is 130 people strong. (SZ 6.6/746)

There are reported to be 18 children in the group in Russia. (W1, 4/7/46)

ARDENNE's secretary who was here in Aug 1945 mentioned that he would rather return barefooted to GERMANY if he could.

a. Herr HOFMANN gets mail about every three weeks. He receives his mail from an office in GRUENAU and sends the answers the same way. Originally a secretary of ARDENNE delivered these letters but it is now done through Russians. Some of the letters are censored by blacking out. Extract from one of the letters:

We arrived first at a place, some 40km (about 24 miles) from MOSCOW. The place is known under the name "Silverwoods". We remained there for about four weeks and then continued our trip to the Caucasus and Black Sea. Here we have a very nice household and two Russian girls who do everthing for us they can. We live directly at the sea. Our laboratory is about 100 m from the house. It was completely empty when we arrived. All apparatus and instruments were brought here

but many pieces were badly damaged. It is so hot that one can hardly put a feet down on a stone floor duing the day. There are plenty of palms, oranges and dates. It is incredibly beautiful.

(These contents are given from memory only) (SZ 2, 1/7/46)

b. RICHTER's sister Mrs. SCHEUNEMANN also gets letters about every three weeks. (FIAT, 3/7/46)

c. ARDENNE's sister Mrs. HARTMANN also gets letters about every three weeks. She is also reported to have pictures of the place where ARDENNE lives.

(W 2,5/7/46)

d. One source had a letter from ARDENNE in February of which the following extracts may be of interest:

compared to LICHTERFELDE the institute here is rather increased. The spectroscope has been somewhat improved here or rather newly constructed for much higher measuring exactness (20000 V anode tension) Major BOUTSCH-BRUGEWITSCH is my person Russian co-worker..... In the long run we and our work have good prspects in this country.

(W2, 5/7/46)

e. ARDENNE is known to be working together with other German scientists at the Chemical and ATOM research station at SUCHUM KALE, a place situated in the Eastern shore of the BLACK Sea.
(ASIA, 1:4,000,000 South Russia, 2nd edition, sheet 20 VI J)
Brit source, 27/7/46)

f. From a letter from Mrs. von ARDENNE the following information is of interest: Due to a scarcity in houses the Russians ordered wooden houses for all the scientists in the project. These houses were ordered from a firm in PRAGUE and should be ready for delivery about this time.

(SZ 5, 30/5/46)

This information was passed on to proper agencies.

Figure D.219: DI 092.-76 FIAT. Subject: Periodic Intelligence Report 1. 2 August 1946 [TNA FO 1031/59]

FA 002/0362. Letter from Major Calvert to Samuel Goudsmit. 8 December 1944. Archive of Deutsches Museum Munich.

[...] A prisoner of war has been located that served as an apprentice with the "Reichspost" in the field of telegraphy. While the prisoner of war is only seventeen years old, he has proven to be very intelligent, fully cooperative, and his statements can be considered reliable. Moreover, he is the son of a Berlin post office employee. In his first interview he made the following statement:

Berlin-Teltow, Mawlower Chaussee (GSGS 4480/3,R6) on open field next to new houses on south side of road, approximately opposite Moltkestrasse. PW states that the building was damaged by air-raid in 43, and about June 43 most of the establishment was transferred to Zeuthen near Berlin. PW went there once to install alarm wires around X-ray tubes (in his own words), which were supposed to be used for experiments in splitting the atom. If the tubes got overheated, the wire was supposed to melt and thus actuate the alarm.

Monthly Intelligence Summary. January 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

II INFORMATION ON POSSIBLE T A SITES

4. Zeuthen:

Information was received from German P/W, who is a former employee of the Reichspost, that there is a high tension apparatus located in the village of Zeuthen near Berlin. P/W stated that he had heard that T A work was in progress at this location. Aerial photos of Zeuthen were obtained and the P/W pinpointed the building to which he referred. The work going on at this building, according to P/W is under the direction of the Reichspost. This information is corroborated to some extent by information previously reported by Dr. S. A. Goudsmit as a result of his Eindhoven investigation.

U.S. Army Air Forces General Henry H. Arnold. 1949. *Global Mission.* New York: Harper. pp. 491, 534. [See also AFHRA 43811 electronic pp. 1080–1081.]

In May, 1943, we received information from Zurich that Professor Max Planck, at the Kaiser Wilhelm Institute, in collaboration with Dr. Otto Hahn, was working on the splitting of the uranium atom. Also that other German scientists were on the threshold of solving this great and dangerous secret.

The Germans were supposed to have perfected an electric machine which would make it possible to complete the development of the atomic bomb. I was then asked to have our bombers in England make special missions against the various branches of the Kaiser Wilhelm Institute in Berlin. Prior to that, the British had destroyed a plant at Norway where the Germans had been experimenting with other phases of this project. [...]

When it came to establishing the Target Folders that would give us the size, location, general characteristics, special distinguishing marks, the type of construction, and other details necessary for bombing operations against a target like the complexes of the I. G. Farben Company, or the Krupp Works—such data did not exist in the United States. Accordingly, the Air Force had no recourse but to go to other sources for its information.

[“An electric machine which would make it possible to complete the development of the atomic bomb” sounds like an electromagnetic separator. Arnold said it was somewhere in the Berlin area and was bombed. The Kaiser Wilhelm Institute is not known to have had such a machine, but the Reichspost did—is that what Arnold meant?]

D.4.4 Uranium-235 Enrichment via Gaseous Diffusion

[Gustav Hertz (German, 1887–1975) developed gaseous diffusion methods of separating isotopes, starting sometime before 1923. See pp. 3619–3629. By 1932 he was achieving and publishing good results demonstrating separation of isotopes other than uranium. Did Hertz or others seriously pursue uranium enrichment via gaseous diffusion in Germany during the Third Reich? He worked at Siemens (one of the two largest German electrical equipment companies) throughout the Third Reich; exactly what he did is unclear, but his work was so important to the government that he was not harmed even though he was partially Jewish. At the end of the war, Stalin was so impressed by whatever he knew of Hertz's wartime work that he offered Hertz his own lab in the Soviet Union, where he then developed gaseous diffusion uranium enrichment methods for the postwar Soviet nuclear weapons program (pp. 3630–3638). Hertz's gaseous diffusion methods were also implemented by scientists at Oak Ridge as one of the main uranium enrichment methods in the United States during and after the war.

In 1927, Erika Cremer (German, 1900–1996) completed her Ph.D. research on (chemical) chain reactions under Max Bodenstein (p. 536). Building upon the pioneering work by Hertz, she began developing improved methods of gaseous diffusion enrichment and gas chromatography in the late 1930s and continued throughout World War II (p. 3640). She worked directly with Otto Hahn and Siegfried Flügge, among others. It seems likely that her work involved gaseous diffusion methods of separating uranium isotopes for the German nuclear program, though little documentation is currently publicly available. Cremer continued to work on gas chromatography after the war, and is best known for her postwar demonstrations and publications on gas chromatography, including those with her student Fritz Prior (Austrian, 1921–1996) [Bobleter 1997].

Hubert Krüger (German, 18??–19??, p. 3629), Rudolf Fleischmann (German, 1903–2002, p. 3639), and others also worked on gaseous diffusion enrichment.

Beginning in 1940, Auergesellschaft [probably Nikolaus Riehl (German, 1901–1990)] patented an industrial-scale uranium enrichment process that appears to have combined aspects of gaseous thermal diffusion and the PUREX process. See pp. 3641–3646. These patent documents prove that Auergesellschaft was involved not only in refining uranium from ore, but also in separating uranium isotopes. They also demonstrate that from the beginning of the war, Germany was interested in developing industrial-scale uranium enrichment, not merely small-scale laboratory experiments.

During the war, Erich Bagge (German, 1912–1996) led a team that invented, built, and demonstrated the "isotope sluice," an alternative form of gaseous diffusion enrichment. See pp. 3651–3662.

Based upon the successful laboratory demonstrations by Gustav Hertz, Erika Cremer, Hubert Krüger, Rudolf Fleischmann, Auergesellschaft, Bagge, and others, did Germany indeed build and operate large-scale gaseous diffusion plants for enriching uranium during the war?]

GUSTAV LUDWIG HERTZ, OF EINDHOVEN, NETHERLANDS, ASSIGNOR TO NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN, OF EINDHOVEN, NETHERLANDS.

METHOD OF SEPARATING GASES FROM MIXTURES THEREOF.

Application filed April 17, 1923. Serial No. 632,798.

To all whom it may concern:

Be it known that I, Dr. GUSTAV LUDWIG HERTZ, a subject of the Republic of Germany, residing at Eindhoven, in the Province of North-Brabant, in the Kingdom of the Netherlands, have invented certain new and useful Improved Methods of Separating Gases from a Mixture Thereof, of which the following is a specification.

This invention relates to an improved method of separating gases from a mixture thereof.

It is known that gases can be separated from a gas mixture by passing the gases through solid screens or through capillary. The method of separating gases according to this invention is based on an entirely new principle.

The method according to the invention is characterised in that a gas mixture is made to diffuse into a gaseous fluid flowing with a predetermined velocity. Preferably the velocity of the gaseous fluid will be regulable and the nature of this fluid will be chosen such that it can be separated from the gas to be isolated or from each of the gases to be isolated. Owing to the different diffusion-coefficients of the different components of the gas mixture the concentration of each of these components in the current of gaseous fluid will have quite a different course. There will be points where the concentration of a certain component, which for instance is most diffusible of all, is relatively high with regard to the concentration of the other less diffusible components.

When removing the gas fraction at such a point a mixture of the flowing gaseous fluid with said component may be obtained in an almost pure condition. By then separating the gaseous fluid from said fraction by a condensation process or a chemical process or in any other suitable manner, the component separated from the primary gas mixture is obtained in an almost pure condition.

At other points in the current of gaseous fluid, the concentration of a second gas component will have increased, which permits of leading away from this point a gas mixture, enriched in the latter component.

The exact course of the method depends on (1) the velocity of the current along that portion of the path where the diffusing process principally takes place (this path may be referred to as "diffusion path"), and (2) the length of this path and (3) the angle made by the latter with the direction of the current of the gaseous fluid.

The current velocity to be chosen of the gaseous fluid depends on the composition of the gas mixture and on the desired results. In order to obtain the maximum output it is advisable to design the apparatus so that it permits of working with the maximum current velocity of the gaseous fluid. In the case of diffusion taking place against the flow of gas, this implies as short a diffusion path as possible.

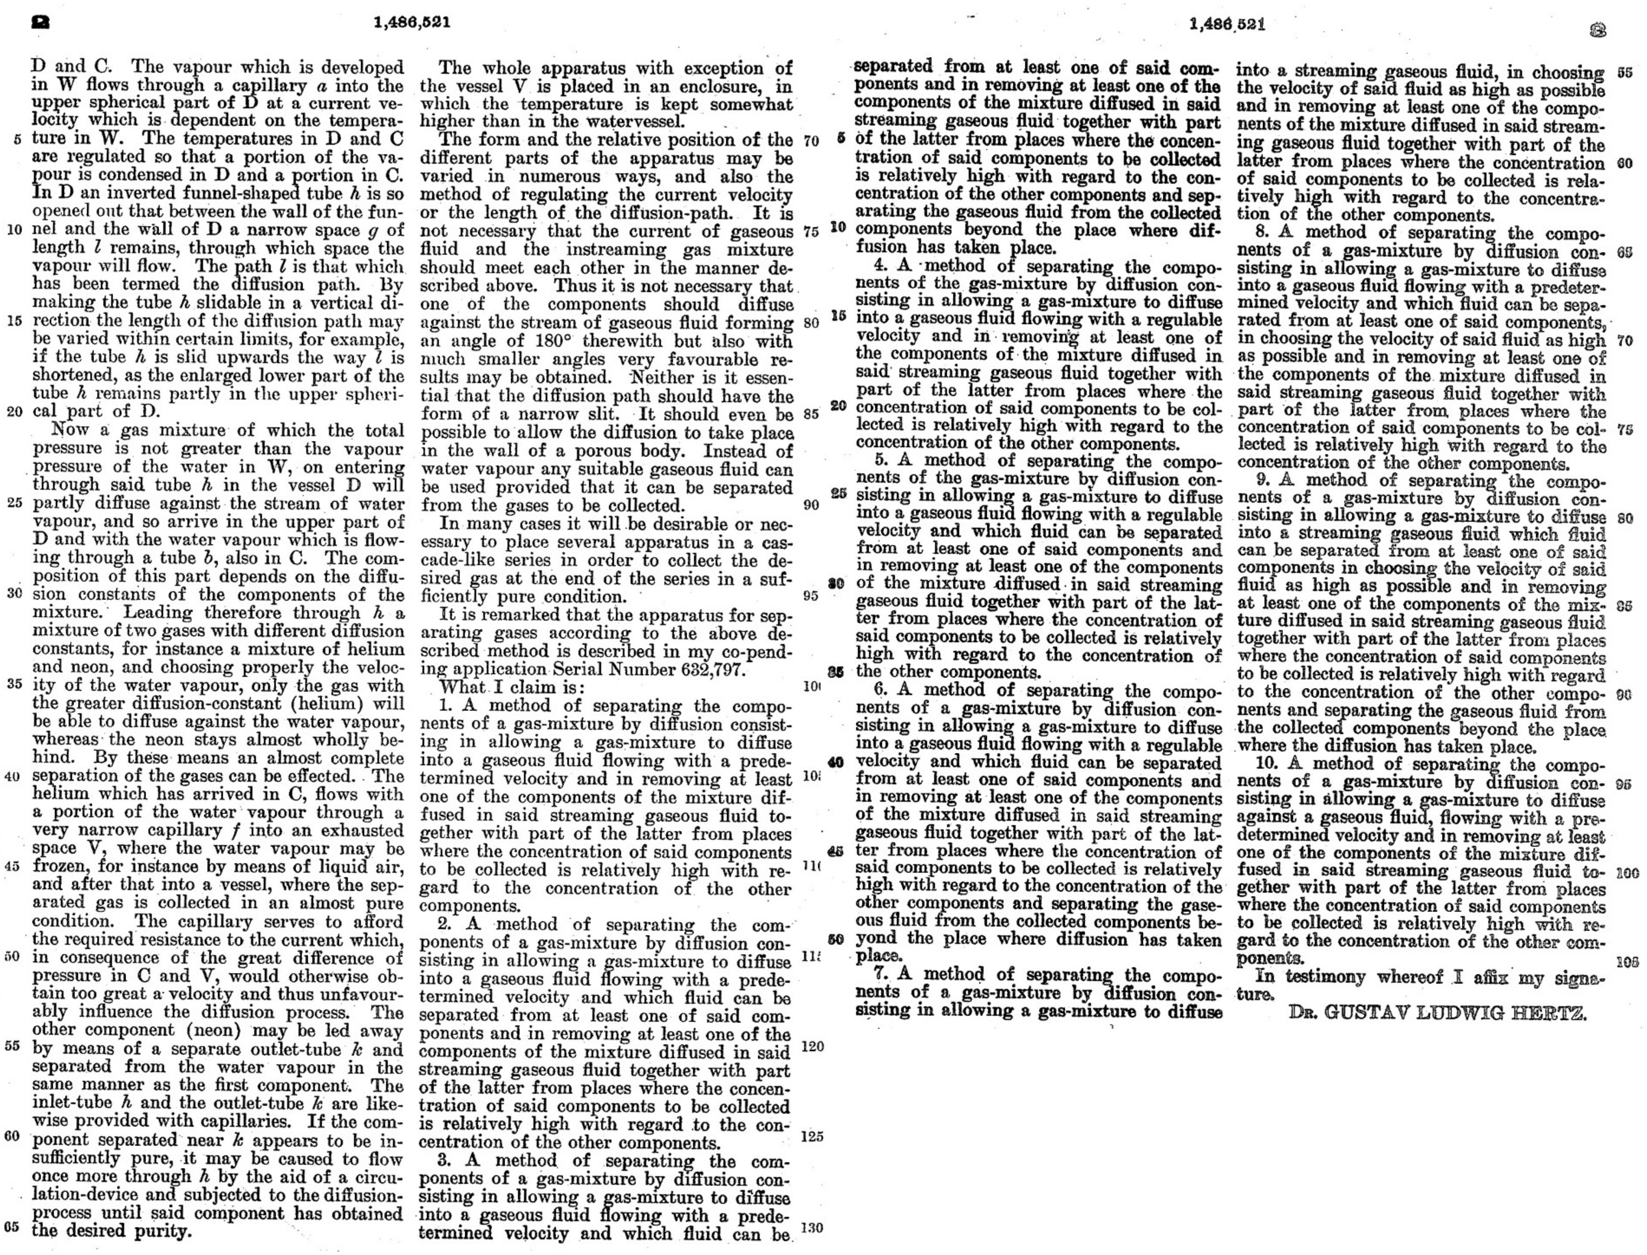
In carrying out the invention a vessel may be used, connected to inlet- and outlet-tubes for the stream of gaseous fluid, for the gas mixture to be separated and for the gases which have diffused apart from each other, while moreover an arrangement can be provided for separating the gaseous fluid from the components of the gas mixture. In addition the apparatus may be provided with means for adjusting the current velocity or the length of the diffusion path or both, which like the arrangement for separating the flowing gaseous fluid from the gas components and other auxiliary arrangements, will be obvious to those skilled in the art.

By arranging the inlet- and outlet-tubes in relation to each other in such a way that the gas component to be separated must diffuse against the current, it is possible to choose the conditions so that only this component is able to do so, the others on the contrary, being led astray by the current to a condenser with which the apparatus, if desired, is provided, while the component which diffused out is led away from a point of great concentration and then liberated from the gaseous fluid.

The drawing diagrammatically represents an apparatus for use in carrying out the invention and in which the gases to be separated are made to diffuse into water vapour.

Referring to the drawing the apparatus consists essentially of three parts: a water vessel W, a diffusion vessel D and a condensation vessel C, which vessels may be in communication as indicated in the drawing. The three vessels, W, D and C are surrounded by waterjackets by means of which their temperature may be exactly adjusted. The temperature in W should be higher than in

Figure D.221: One of Gustav Hertz's first patents on gaseous diffusion for enrichment, filed in 1923 [U.S. Patent 1,486,521. Method of Separating Gases from a Mixture Thereof].



2 1,486,521

D and C. The vapour which is developed in W flows through a capillary *a* into the upper spherical part of D at a current velocity which is dependent on the temperature in W. The temperatures in D and C are regulated so that a portion of the vapour is condensed in D and a portion in C. In D an inverted funnel-shaped tube *h* is so opened out that between the wall of the funnel and the wall of D a narrow space *g* of length *l* remains, through which space the vapour will flow. The path *l* is that which has been termed the diffusion path. By making the tube *h* slidable in a vertical direction the length of the diffusion path may be varied within certain limits, for example, if the tube *h* is slid upwards the way *l* is shortened, as the enlarged lower part of the tube *h* remains partly in the upper spherical part of D.

Now a gas mixture of which the total pressure is not greater than the vapour pressure of the water in W, on entering through said tube *h* in the vessel D will partly diffuse against the stream of water vapour, and so arrive in the upper part of D and with the water vapour which is flowing through a tube *b*, also in C. The composition of this part depends on the diffusion constants of the components of the mixture. Leading therefore through *h* a mixture of two gases with different diffusion constants, for instance a mixture of helium and neon, and choosing properly the velocity of the water vapour, only the gas with the greater diffusion-constant (helium) will be able to diffuse against the water vapour, whereas the neon stays almost wholly behind. By these means an almost complete separation of the gases can be effected. The helium which has arrived in C, flows with a portion of the water vapour through a very narrow capillary *f* into an exhausted space V, where the water vapour may be frozen, for instance by means of liquid air, and after that into a vessel, where the separated gas is collected in an almost pure condition. The capillary serves to afford the required resistance to the current which, in consequence of the great difference of pressure in C and V, would otherwise obtain too great a velocity and thus unfavourably influence the diffusion process. The other component (neon) may be led away by means of a separate outlet-tube *k* and separated from the water vapour in the same manner as the first component. The inlet-tube *h* and the outlet-tube *k* are likewise provided with capillaries. If the component separated near *k* appears to be insufficiently pure, it may be caused to flow once more through *h* by the aid of a circulation-device and subjected to the diffusion-process until said component has obtained the desired purity.

The whole apparatus with exception of the vessel V is placed in an enclosure, in which the temperature is kept somewhat higher than in the watervessel.

The form and the relative position of the different parts of the apparatus may be varied in numerous ways, and also the method of regulating the current velocity or the length of the diffusion-path. It is not necessary that the current of gaseous fluid and the instreaming gas mixture should meet each other in the manner described above. Thus it is not necessary that one of the components should diffuse against the stream of gaseous fluid forming an angle of 180° therewith but also with much smaller angles very favourable results may be obtained. Neither is it essential that the diffusion path should have the form of a narrow slit. It should even be possible to allow the diffusion to take place in the wall of a porous body. Instead of water vapour any suitable gaseous fluid can be used provided that it can be separated from the gases to be collected.

In many cases it will be desirable or necessary to place several apparatus in a cascade-like series in order to collect the desired gas at the end of the series in a sufficiently pure condition.

It is remarked that the apparatus for separating gases according to the above described method is described in my co-pending application Serial Number 632,797.

What I claim is:

1. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a predetermined velocity and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

2. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a predetermined velocity and which fluid can be separated from at least one of said components and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

3. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a predetermined velocity and which fluid can be separated from at least one of said components and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components and separating the gaseous fluid from the collected components beyond the place where diffusion has taken place.

4. A method of separating the components of the gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a regulable velocity and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

5. A method of separating the components of the gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a regulable velocity and which fluid can be separated from at least one of said components and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

6. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a regulable velocity and which fluid can be separated from at least one of said components and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components and separating the gaseous fluid from the collected components beyond the place where diffusion has taken place.

7. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a streaming gaseous fluid, in choosing the velocity of said fluid as high as possible and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

8. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a gaseous fluid flowing with a predetermined velocity and which fluid can be separated from at least one of said components, in choosing the velocity of said fluid as high as possible and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

9. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse into a streaming gaseous fluid which fluid can be separated from at least one of said components in choosing the velocity of said fluid as high as possible and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components and separating the gaseous fluid from the collected components beyond the place where the diffusion has taken place.

10. A method of separating the components of a gas-mixture by diffusion consisting in allowing a gas-mixture to diffuse against a gaseous fluid, flowing with a predetermined velocity and in removing at least one of the components of the mixture diffused in said streaming gaseous fluid together with part of the latter from places where the concentration of said components to be collected is relatively high with regard to the concentration of the other components.

In testimony whereof I affix my signature.

GUSTAV LUDWIG HERTZ, OF EINDHOVEN, NETHERLANDS, ASSIGNOR TO NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPENFABRIEKEN, OF EINDHOVEN, NETHERLANDS.

APPARATUS FOR SEPARATING GASES FROM A MIXTURE THEREOF.

Application filed April 17, 1923. Serial No. 632,797.

To all whom it may concern:

Be it known that I, Dr. Gustav Ludwig Hertz, a subject of the Republic of Germany, residing at Eindhoven, in the Province of North Brabant, in the Kingdom of the Netherlands, have invented certain new and useful Improvements in or Relating to an Apparatus for Separating Gases from a Mixture Thereof, of which the following is a specification.

This invention relates to an apparatus for separating gases from a mixture thereof.

It is known that gases can be separated from a gas mixture by passing the gases through a suitable screen or through capillary means. The apparatus for separating gases according to this invention is based on the appliance of an entirely new principle.

According to the latter a gas mixture is made to diffuse into a gaseous fluid flowing with a predetermined velocity. Preferably the velocity of the gaseous fluid will be regulable and the nature of this fluid will be such that it can be separated from the gas to be isolated or from each of the gases to be isolated. Owing to the different diffusion-coefficients of the different components of the gas mixture the concentration of each of these components in the current of auxiliary gas will have quite a different course. There will be points where the concentration of a certain component, which for instance is most diffusible of all, is relatively high with regard to the concentration of the other less diffusible components.

When removing the gas fraction at such a point a mixture of the flowing gaseous fluid with said component may be obtained in an almost pure condition. By then separating the auxiliary gas from said fraction by a condensation process or a chemical process or in any other suitable manner, the component separated from the primary gas mixture is obtained in an almost pure condition.

In other points of the current of gaseous fluid, the concentration of a second gas component will have increased, which permits of leading away from this point a gas mixture, enriched in the latter component.

The exact course of the method depends on (1) the velocity of the current along that portion of the path where the diffusing process principally takes place (this path may be referred to as the "diffusion path"), and (2) the length of this path and (3) the angle made by the latter with the direction of the current of the gaseous fluid.

The current velocity to be chosen of the gaseous fluid depends on the composition of the gas mixture and on the desired results. In order to obtain the maximum output it is advisable to design the apparatus so that it permits of working with the maximum current velocity of the auxiliary gas. In the case of diffusion taking place against the flow of gas, this implies as short a diffusion path as possible.

The apparatus according to the invention may contain a vessel, connected to inlet- and outlet-devices for the stream of gaseous fluid, for the gas mixture to be separated and for the gases which have diffused apart from each other, while moreover an arrangement can be provided for separating the streaming gaseous fluid from the components of the gas mixture. In addition the apparatus may be provided with means for adjusting the current velocity or the length of the diffusion path or both, which like the arrangement for separating the flowing gaseous fluid from the gas components and other auxiliary arrangements, will be obvious to those skilled in the art.

By arranging the inlet- and outlet-tubes in relation to each other in such a way that the gas component to be separated must diffuse against the current, it is possible to choose the conditions so that only this component is able to do so, the others on the contrary, being led astray by the current to a condenser with which the apparatus, if desired, is provided, while the component which has diffused cut is led away from a point of great concentration and then liberated from the anxiliary gas.

The drawing diagrammatically represents an apparatus according to the invention and in which the gases to be separated are made to diffuse into water vapour.

Referring to the drawing the apparatus consists essentially of three parts: a water vessel W, a diffusion vessel D and a condensation vessel C, which vessels may be in communication as indicated in the drawing. The three vessels W, D and C are sur-

rounded by water-jackets by means of which their temperature may be exactly adjusted. The temperature in W should be higher than in D and C. The vapour which is developed in W flows through a capillary a into the upper spherical part of D at a current velocity which is dependent on the temperature in W. The temperatures in D and C are regulated so that a portion of the vapour is condensed in D and a portion in C. In D an inverted funnel-shaped tube h is so opened out that between the wall of the funnel and the wall of D a narrow space g of length l remains, through which space the vapour will flow. The path l is that which has been termed the diffusion path. By making the tube h slidable in a vertical direction the length of the diffusion path may be varied within certain limits.

Now a gas mixture of which the total pressure is not greater than the vapour pressure of the water in W, on entering through said tube h in the vessel D will partly diffuse against the stream of water vapour, and so arrive in the upper part of D and with the water vapour which is flowing through a tube b, also in C. The composition of this part depends on the diffusion constants of the components of the mixture. Leading therefore through h a mixture of two gases with different diffusion constants, for instance a mixture of helium and neon, and choosing properly the velocity of the water vapour, only the gas with the greater diffusion-constant (helium) will be able to diffuse against the water vapour, whereas the neon stays almost wholly behind. By these means an almost complete separation of the gases can be effected. The helium which has arrived in C, flows with a portion of the water vapour through a very narrow capillary f into an exhausted space V, where the water vapour may be frozen, for instance by means of liquid air, and after that into a vessel, where the separated gas is collected in an almost pure condition. The capillary serves to afford the required resistance to the current which, in consequence of the great difference of pressure in C and V, would otherwise obtain too great a velocity and thus unfavourably influence the diffusion process. The other component (neon) may be led away by means of a separate outlet-tube k and separated from the water vapour in the same manner as the first component. The inlet-tube h and the outlet-tube k are likewise provided with capillaries. If the component separated near k appears to be insufficiently pure, it may be caused to flow once more through h by the aid of a circulation-device and subjected to the diffusion-process until said component has obtained the desired purity.

The whole apparatus with exception of the vessel V is placed in an enclosure, in which the temperature is kept somewhat higher than in the water vessel.

The form and the relative position of the different parts of the apparatus may be varied in numerous ways, and also the method of regulating the current velocity or the length of the diffusion path. It is not necessary that the current of auxiliary gas and the instreaming gas mixture should meet each other in the manner described above. Thus it is not necessary that one of the components should diffuse against the stream of auxiliary gas forming an angle of 180° therewith for with much smaller angles very favourable results may also be obtained. Neither it is essential that the diffusion path should have the form of a narrow slit. It should even be possible to allow the diffusion to take place in the wall of a porous body.

Instead of water vapour any other suitable gaseous fluid can be used provided that it can be separated from the gases to be collected.

In many cases it will be desirable or necessary to place several apparatus in a cascade-like series in order to collect the desired gas at the end of the series in a sufficiently pure condition.

It is remarked that the method for separating gases from a mixture by diffusion is described in my co-pending application Serial Number 632,798, filed April 17, 1923.

What I claim is:

1. Apparatus for separating the components of a gas mixture comprising in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas-components to be collected is relatively higher than that of the other components.

2. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas-components to be collected is relatively higher than that of the other components, and means for separating the streaming gaseous fluid from the collected components beyond the place where the diffusion has taken place.

3. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said ves-

sel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components and means for regulating the current velocity of the streaming gaseous fluid.

4. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, and means for regulating the length of the diffusion path.

5. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, means for regulating the current velocity of the streaming fluid and means for regulating the length of the diffusion path.

6. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components means for separating the streaming gaseous fluid from the collected components beyond the place where diffusion has taken place and means for regulating the current velocity of the streaming gaseous fluid.

7. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, means for separating the streaming gaseous fluid from the collected components beyond the place where the diffusion has taken place and means for regulating the length of the diffusion path.

8. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other; components means for separating the streaming gaseous fluid from the collected components beyond the place where diffusion has taken place means for regulating the current velocity of the streaming gaseous fluid and means for regulating the length of the diffusion path.

9. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, the feeding- and outlet-devices being arranged in such relative position that at least one of the gas components to be collected must diffuse against the stream of gaseous fluid.

10. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, the feeding- and outlet-devices being arranged in such relative position that at least one of the gas components to be collected must diffuse against the stream of gaseous fluid and means for separating the streaming gaseous fluid from the collecting components beyond the place where the diffusion has taken place.

11. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is

relatively higher than that of the other components, the feeding- and outlet-devices being arranged in such relative position that at least one of the gas components to be collected must diffuse against the stream of gaseous fluid and means for regulating the current velocity of the streaming gaseous fluid.

12. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, the feeding- and outlet-devices being arranged in such relative position that at least one of the gas components to be collected must diffuse against the stream of gaseous fluid means for separating the streaming gaseous fluid from the collected components beyond the place where the diffusion has taken place and means for regulating the current velocity of the streaming gaseous fluid.

13. In an apparatus for separating the components of a gas mixture in combination a vessel, devices for feeding a streaming gaseous fluid to said vessel, devices for feeding a gas mixture to be diffused to said vessel, outlet devices comprising outlet paths to conduct the gases diffused away from each other, the outlet paths beginning at places where the concentration of the gas components to be collected is relatively higher than that of the other components, the feeding- and outlet-devices being arranged in such relative position that at least one of the gas components to be collected must diffuse against the stream of gaseous fluid, means for separating the streaming gaseous fluid from the collected components beyond the place where the diffusion has taken place, means for regulating the current velocity of the streaming gaseous fluid and means for a diffusion path for said mixture as short as is practically possible.

In testimony whereof I affix my signature.

Klasse 12 d. **Ausgegeben am 25. Oktober 1927.**

ÖSTERREICHISCHES PATENTAMT.

PATENTSCHRIFT Nr. 107571.

N. V. PHILIPS' GLOEILAMPENFABRIEKEN IN EINDHOVEN.

Verfahren zur ununterbrochenen Trennung eines Gasgemisches.

Angemeldet am 27. Oktober 1925; Priorität der Anmeldung in den Niederlanden vom 21. August 1925 beansprucht.

Beginn der Patentdauer: 15. Mai 1927.

Als Erfinder wird genannt: Dr. Gustav Ludwig Hertz in Eindhoven.

Die Erfindung betrifft ein Verfahren zur ununterbrochenen Trennung eines Gasgemisches.

Gewöhnlich wird die Trennung eines Gasgemisches dadurch herbeigeführt, daß dieses auf eine niedrige Temperatur gebracht wird, wodurch eine der Komponenten flüssig wird, oder daß das Gasgemisch durch eine poröse Wand oder in ein strömendes Gas geführt wird. Eine der in dieser Weise erhaltenen Fraktionen kann dann wiederum dem gleichen Trennungsverfahren unterworfen und dieses so oft wiederholt werden, bis man eine Fraktion der gewünschten Zusammensetzung erhält. Abgesehen davon, daß man bei diesem Vorgehen sehr schwer zu einer ununterbrochen arbeitenden Trennungsmethode gelangen kann, hat eine Trennungsmethode, die immer auf eine einzige Fraktion (selbstverständlich die erste oder die letzte Fraktion) angewendet wird, den Nachteil, daß die andern Fraktionen, die noch einen bedeutenden Teil des zu gewinnenden Gases enthalten können, unbenutzt bleiben.

Das vorliegende Verfahren zur Trennung eines Gasgemisches kann nicht nur in ununterbrochenem Betrieb ausgeführt werden, sondern es wird hiebei auch jede gerade gebildete Fraktion selbsttätig einer neuen Entmischung unterworfen. Auf diese Weise kann die Trennung eines Gasgemisches weiter durchgeführt werden, als dies gemäß den bisher bekannten Methoden möglich war und auch die Ausbeute der abgeschiedenen Gase kann vergrößert werden.

Verfahren zur fortschreitenden Trennung eines Gasgemisches sind bekannt. Gemäß denselben wird eine Reihe von Entmischungselementen verwendet, von denen jedes für sich imstande ist, eine teilweise Entmischung in zwei oder mehr Fraktionen herbeizuführen. Auf diese Weise kann die Trennung eines Gasgemisches weiter durchgeführt werden, wodurch es möglich ist, die Ausbeute der abgeschiedenen Gase zu vergrößern.

Gemäß der Erfindung besteht das Verfahren darin, daß eine Reihe von Entmischungselementen verwendet wird, deren jedes für sich eine teilweise Entmischung in zwei oder mehr Fraktionen herbeiführt, die je nach ihrer Zusammensetzung zwei oder mehr Entmischungselementen auf beiden Seiten oder auch dem betreffenden Entmischungselement selbst zugeführt werden. Dabei sind unter Entmischungselementen auf beiden Seiten nicht nur die unmittelbar benachbarten Entmischungselemente, sondern überhaupt alle andern um das berücksichtigte Entmischungselement liegenden Entmischungselemente zu verstehen. Zweckmäßig wird die Trennung derart ausgeführt, daß die von einem Entmischungselement einem zweiten Entmischungselement zugeführte Gasmenge nahezu gleich der von dem zweiten Entmischungselement dem ersten zugeführten Gasmenge ist. Auch kann die Trennung derart ausgeführt werden, daß die den Entmischungselementen auf einer Seite eines bestimmten Entmischungselementes zugeführte Gasmenge nahezu gleich der den Entmischungselementen auf der andern Seite zugeführten Gasmenge ist. Dabei ist unter Menge das Volumen bei gleichem Druck und gleicher Temperatur, d. h. die Anzahl der Moleküle, zu verstehen.

Dieses Verfahren kann mit Hilfe einer Reihe von Vorrichtungen ausgeführt werden, deren jede für sich eine teilweise Trennung des Gasgemisches herbeiführen kann und die von bekannter Form bzw. Bauart sein können. Wird einem solchen Entmischungselement, z. B. *c*, ein Gasgemisch bestimmter Zusammensetzung zugeführt, so wird, nachdem in diesem Element eine teilweise Entmischung stattgefunden hat, die Zusammensetzung der in dieser Weise gebildeten Fraktionen von der Zusammensetzung des ursprünglichen Gasgemisches abweichen. Jeder dieser Fraktionen entzieht man, z. B. mittels Pumpen, einen Teil der dabei andern Entmischungselementen oder auch demselben Entmischungselement zugeführt wird; z. B. wenn im Entmischungselement *c* zwei Fraktionen gebildet worden sind, so kann die eine Fraktion dem vorigen Entmischungselement *b*, und die andere dem folgenden Element *d* zugeführt werden. Die dem Element *b* zugeführte Fraktion wird hier wieder eine teilweise Entmischung erfahren und in zwei Unterfraktionen zerlegt werden, von denen die eine dem vorigen Entmischungselement *a* und die andere dem Element *c* zugeführt werden kann. Ähnliches wird mit der dem Entmischungselement *d* bzw. mit jeder einem vorigen oder einem folgenden Entmischungselement zugeführten Fraktion geschehen. Im allgemeinen werden in einem bestimmten Entmischungselement zwei oder mehr von andern Entmischungselementen oder auch von demselben Element herkommende Fraktionen zusammenkommen; das in dieser Weise entstandene Gasgemisch wird dann durch die Entmischung wieder in zwei oder mehrere Fraktionen geteilt werden, die wieder andern Entmischungselementen oder auch demselben Entmischungselement zugeführt werden. Die im ersten und im letzten Entmischungselement befindlichen Gasgemische werden ihrer Zusammensetzung nach am meisten verschieden sein und am meisten von der Komponente befreit sein, die man mittels der Trennung zu entfernen wünscht. Will man die Trennung derart ausführen, daß die von einem Entmischungselement einem zweiten zugeführte Gasmenge nahezu gleich der von dem zweiten Element dem ersten zugeführten Gasmenge ist, so kann man zu diesem Zwecke den Widerstand des Weges vom ersten Entmischungselement zum zweiten nahezu gleich dem Widerstand des Weges vom zweiten Entmischungselement zum ersten machen. Wird die Trennung in einem Entmischungselement dadurch herbeigeführt, daß man das Gas durch eine poröse Wand diffundieren läßt, so kann gemäß der Erfindung der Widerstand des einen Weges praktisch durch die poröse Wand bestimmt werden, während der Widerstand des andern Weges durch eine geeignete Wahl des Durchmessers oder der Länge der zu diesem Zwecke verwendeten Röhre dem vorher erwähnten Widerstand ungefähr gleich gemacht wird. Dabei muß man aber berücksichtigen, daß der Durchmesser dieser Röhre im allgemeinen nicht so klein sein darf, daß in derselben Entmischungserscheinungen auftreten und daher die regelmäßige Durchströmung gestört wird. Um das Auftreten von Entmischungserscheinungen zu vermeiden, kann man den Durchmesser der Röhre größer wählen, als die freie Weglänge der Moleküle des hindurchströmenden Gases beträgt. Es kann jedoch eine Röhre, deren Durchmesser so klein ist, daß Entmischungserscheinungen auftreten, z. B. ein Haarröhrchen, verwendet werden, wenn ihm nur eine weite Röhre von solcher Länge vorgeschaltet wird, daß an dem vom Haarröhrchen am weitesten entfernten Ende dieser weiten Röhre Entmischungserscheinungen nicht auftreten.

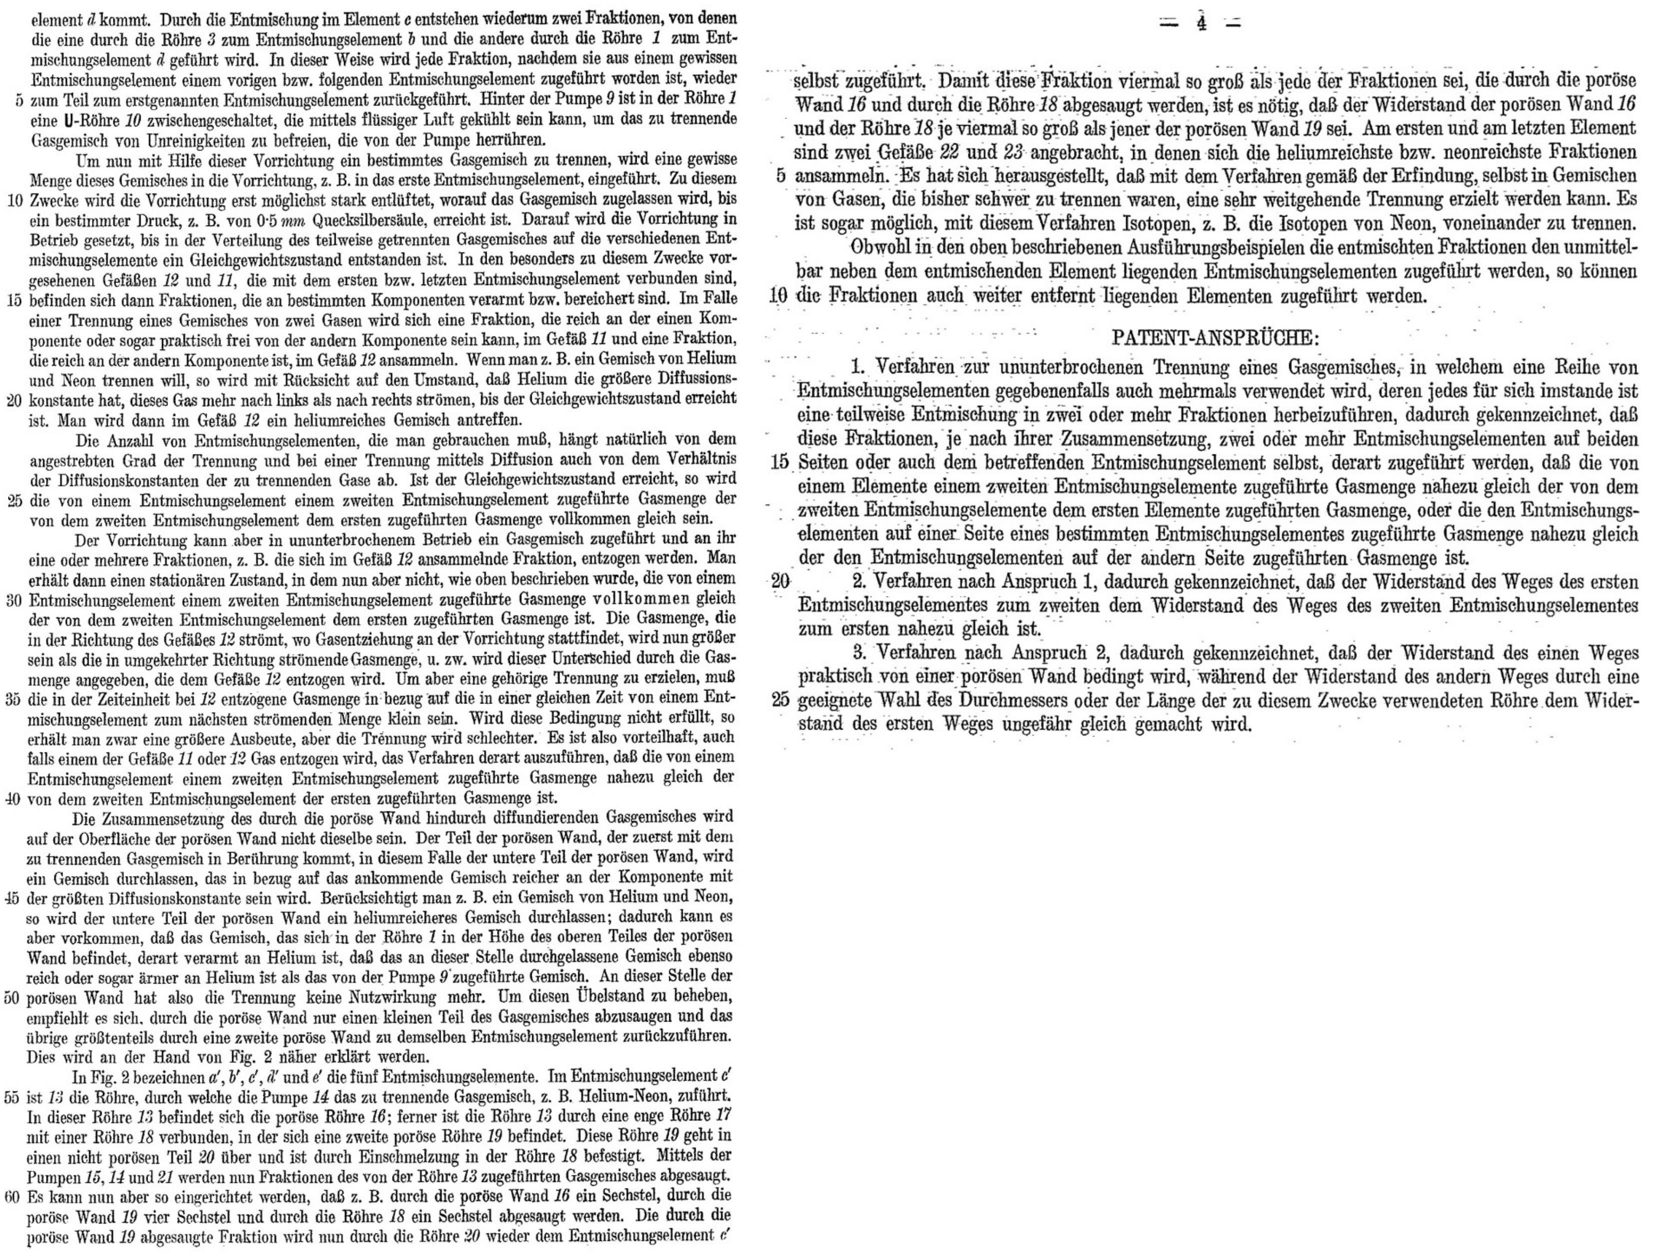
Da jedem Entmischungselement eine gewisse Menge der in diesem Element erzeugten Fraktionen entzogen werden muß, müssen Mittel zum Regeln dieser Entziehung vorgesehen werden. Zweckmäßig geschieht die Entziehung der Fraktionen an jedem der Entmischungselemente mit Hilfe von Pumpen. Obwohl zum Absaugen jeder Fraktion eine einzelne Pumpe verwendet werden kann, empfiehlt es sich häufig, mehrere von verschiedenen Entmischungselementen herkommenden Fraktionen mit einer einzigen Pumpe abzusaugen. So kann z. B. die Entziehung einer Fraktion an einem vorigen und die einer andern Fraktion an einem folgenden Entmischungselement mit einer einzigen Pumpe ausgeführt werden. In der Regel werden zum Ausführen des Verfahrens Pumpen verwendet, deren Leistungen gleich groß sind.

Anstatt eine Trennungsmethode mittels Diffusion durch eine poröse Wand zu benutzen, kann die Trennung in den Entmischungselementen auch durch jedes andere an sich bekannte Trennungsverfahren stattfinden.

Das Verfahren gemäß der Erfindung wird an Hand der beigefügten Zeichnung erläutert, in der in Fig. 1 eine Vorrichtung dargestellt ist, die aus fünf hintereinandergeschalteten Entmischungselementen besteht, deren jedes für sich eine teilweise Entmischung dadurch herbeiführt, daß das Gasgemisch zum Teil durch eine poröse Wand diffundiert. Fig. 2 stellt eine Vorrichtung dar, die gleichfalls aus fünf Entmischungselementen besteht, in der aber jedes Entmischungselement zwei poröse Wände enthält, deren jede eine teilweise Trennung herbeiführen kann.

In Fig. 1 sind *a*, *b*, *c*, *d* und *e* die fünf Entmischungselemente. Wenn man eines dieser Entmischungselementen z. B. *c* ins Auge faßt, so bezeichnet *1* eine Röhre, durch die das Gasgemisch nach *c* strömt, *2* ist eine mit einer porösen Wand versehene Röhre, die unten abgeschlossen ist und z. B. aus aufgerolltem Papier bestehen kann; sie befindet sich im Innern der Röhre *1* und ist mit dieser derart verbunden, daß eine Gasströmung von der Röhre *1* nach der Röhre *2* ausschließlich durch die poröse Wand hindurch stattfinden kann. Zu diesem Zweck ist das obere Ende der Röhre *1*, die aus Glas bestehen kann, durch Verschmelzung an einer Röhre *3* befestigt, welche die Verlängerung der Röhre *2* ist. Die Röhre *1* ist am oberen Ende umgebogen und ist unter Zwischenschaltung der engen Röhre *4* mit der Pumpe *5* verbunden, die das durch das Entmischungselement *d* zu trennende Gasgemisch zuführt, während die Röhre *3* mit der Pumpe *6* verbunden ist, die das durch das Entmischungselement *b* zu trennende Gasgemisch zuführt. Der Widerstand, den das durch die poröse Wand strömende Gas findet, ist dem Widerstand der engen Röhre *4* nahezu gleich. In das Entmischungselement *c* werden nun mittels der Pumpe *9* zwei Fraktionen zusammengebracht, von denen die eine durch die enge Röhre *7* zugeführt wird und von dem Entmischungselement *b* herkommt, während die andere durch die Röhre *8* strömt und von dem Entmischungs-

Figure D.225: One of Gustav Hertz's patents showing that many gaseous diffusion units could be used in series to achieve high-quality enrichment [Austrian Patent AT 107,571. Verfahren zur ununterbrochenen Trennung eines Gasgemisches].



element *d* kommt. Durch die Entmischung im Element *c* entstehen wiederum zwei Fraktionen, von denen die eine durch die Röhre *3* zum Entmischungselement *b* und die andere durch die Röhre *1* zum Entmischungselement *d* geführt wird. In dieser Weise wird jede Fraktion, nachdem sie aus einem gewissen Entmischungselement einem vorigen bzw. folgenden Entmischungselement zugeführt worden ist, wieder zum Teil zum erstgenannten Entmischungselement zurückgeführt. Hinter der Pumpe *9* ist in der Röhre *1* eine U-Röhre *10* zwischengeschaltet, die mittels flüssiger Luft gekühlt sein kann, um das zu trennende Gasgemisch von Unreinigkeiten zu befreien, die von der Pumpe herrühren.

Um nun mit Hilfe dieser Vorrichtung ein bestimmtes Gasgemisch zu trennen, wird eine gewisse Menge dieses Gemisches in die Vorrichtung, z. B. in das erste Entmischungselement, eingeführt. Zu diesem Zwecke wird die Vorrichtung erst möglichst stark entlüftet, worauf das Gasgemisch zugelassen wird, bis ein bestimmter Druck, z. B. von 0·5 *mm* Quecksilbersäule, erreicht ist. Darauf wird die Vorrichtung in Betrieb gesetzt, bis in der Verteilung des teilweise getrennten Gasgemisches auf die verschiedenen Entmischungselemente ein Gleichgewichtszustand entstanden ist. In den besonders zu diesem Zwecke vorgesehenen Gefäßen *12* und *11*, die mit dem ersten bzw. letzten Entmischungselement verbunden sind, befinden sich dann Fraktionen, die an bestimmten Komponenten verarmt bzw. bereichert sind. Im Falle einer Trennung eines Gemisches von zwei Gasen wird sich eine Fraktion, die reich an der einen Komponente oder sogar praktisch frei von der andern Komponente sein kann, im Gefäß *11* und eine Fraktion, die reich an der andern Komponente ist, im Gefäß *12* ansammeln. Wenn man z. B. ein Gemisch von Helium und Neon trennen will, so wird mit Rücksicht auf den Umstand, daß Helium die größere Diffusionskonstante hat, dieses Gas mehr nach links als nach rechts strömen, bis der Gleichgewichtszustand erreicht ist. Man wird dann im Gefäß *12* ein heliumreiches Gemisch antreffen.

Die Anzahl von Entmischungselementen, die man gebrauchen muß, hängt natürlich von dem angestrebten Grad der Trennung und bei einer Trennung mittels Diffusion auch von dem Verhältnis der Diffusionskonstanten der zu trennenden Gase ab. Ist der Gleichgewichtszustand erreicht, so wird die von einem Entmischungselement einem zweiten Entmischungselement zugeführte Gasmenge der von dem zweiten Entmischungselement dem ersten zugeführten Gasmenge vollkommen gleich sein.

Der Vorrichtung kann aber in ununterbrochenem Betrieb ein Gasgemisch zugeführt und an ihr eine oder mehrere Fraktionen, z. B. die sich im Gefäß *12* ansammelnde Fraktion, entzogen werden. Man erhält dann einen stationären Zustand, in dem nun aber nicht, wie oben beschrieben wurde, die von einem Entmischungselement einem zweiten Entmischungselement zugeführte Gasmenge vollkommen gleich der von dem zweiten Entmischungselement dem ersten zugeführten Gasmenge ist. Die Gasmenge, die in der Richtung des Gefäßes *12* strömt, wo Gasentziehung an der Vorrichtung stattfindet, wird nun größer sein als die in umgekehrter Richtung strömende Gasmenge, u. zw. wird dieser Unterschied durch die Gasmenge angegeben, die dem Gefäße *12* entzogen wird. Um aber eine gehörige Trennung zu erzielen, muß die in der Zeiteinheit bei *12* entzogene Gasmenge in bezug auf die in einer gleichen Zeit von einem Entmischungselement zum nächsten strömenden Menge klein sein. Wird diese Bedingung nicht erfüllt, so erhält man zwar eine größere Ausbeute, aber die Trennung wird schlechter. Es ist also vorteilhaft, auch falls einem der Gefäße *11* oder *12* Gas entzogen wird, das Verfahren derart auszuführen, daß die von einem Entmischungselement einem zweiten Entmischungselement zugeführte Gasmenge nahezu gleich der von dem zweiten Entmischungselement der ersten zugeführten Gasmenge ist.

Die Zusammensetzung des durch die poröse Wand hindurch diffundierenden Gasgemisches wird auf der Oberfläche der porösen Wand nicht dieselbe sein. Der Teil der porösen Wand, der zuerst mit dem zu trennenden Gasgemisch in Berührung kommt, in diesem Falle der untere Teil der porösen Wand, wird ein Gemisch durchlassen, das in bezug auf das ankommende Gemisch reicher an der Komponente mit der größten Diffusionskonstante sein wird. Berücksichtigt man z. B. ein Gemisch von Helium und Neon, so wird der untere Teil der porösen Wand ein heliumreicheres Gemisch durchlassen; dadurch kann es aber vorkommen, daß das Gemisch, das sich in der Röhre *1* in der Höhe des oberen Teiles der porösen Wand befindet, derart verarmt an Helium ist, daß das an dieser Stelle durchgelassene Gemisch ebenso reich oder sogar ärmer an Helium ist als das von der Pumpe *9* zugeführte Gemisch. An dieser Stelle der porösen Wand hat also die Trennung keine Nutzwirkung mehr. Um diesen Übelstand zu beheben, empfiehlt es sich, durch die poröse Wand nur einen kleinen Teil des Gasgemisches abzusaugen und das übrige größtenteils durch eine zweite poröse Wand zu demselben Entmischungselement zurückzuführen. Dies wird an der Hand von Fig. 2 näher erklärt werden.

In Fig. 2 bezeichnen *a′*, *b′*, *c′*, *d′* und *e′* die fünf Entmischungselemente. Im Entmischungselement *c′* ist *13* die Röhre, durch welche die Pumpe *14* das zu trennende Gasgemisch, z. B. Helium-Neon, zuführt. In dieser Röhre *13* befindet sich die poröse Röhre *16*; ferner ist die Röhre *13* durch eine enge Röhre *17* mit einer Röhre *18* verbunden, in der sich eine zweite poröse Röhre *19* befindet. Diese Röhre *19* geht in einen nicht porösen Teil *20* über und ist durch Einschmelzung in der Röhre *18* befestigt. Mittels der Pumpen *15*, *14* und *21* werden nun Fraktionen des von der Röhre *13* zugeführten Gasgemisches abgesaugt. Es kann nun aber so eingerichtet werden, daß z. B. durch die poröse Wand *16* ein Sechstel, durch die poröse Wand *19* vier Sechstel und durch die Röhre *18* ein Sechstel abgesaugt werden. Die durch die poröse Wand *19* abgesaugte Fraktion wird nun durch die Röhre *20* wieder dem Entmischungselement *c′* selbst zugeführt. Damit diese Fraktion viermal so groß als jede der Fraktionen sei, die durch die poröse Wand *16* und durch die Röhre *18* abgesaugt werden, ist es nötig, daß der Widerstand der porösen Wand *16* und der Röhre *18* je viermal so groß als jener der porösen Wand *19* sei. Am ersten und am letzten Element sind zwei Gefäße *22* und *23* angebracht, in denen sich die heliumreichste bzw. neonreichste Fraktionen ansammeln. Es hat sich herausgestellt, daß mit dem Verfahren gemäß der Erfindung, selbst in Gemischen von Gasen, die bisher schwer zu trennen waren, eine sehr weitgehende Trennung erzielt werden kann. Es ist sogar möglich, mit diesem Verfahren Isotopen, z. B. die Isotopen von Neon, voneinander zu trennen.

— 4 —

Obwohl in den oben beschriebenen Ausführungsbeispielen die entmischten Fraktionen den unmittelbar neben dem entmischenden Element liegenden Entmischungselementen zugeführt werden, so können die Fraktionen auch weiter entfernt liegenden Elementen zugeführt werden.

PATENT-ANSPRÜCHE:

1. Verfahren zur ununterbrochenen Trennung eines Gasgemisches, in welchem eine Reihe von Entmischungselementen gegebenenfalls auch mehrmals verwendet wird, deren jedes für sich imstande ist eine teilweise Entmischung in zwei oder mehr Fraktionen herbeizuführen, dadurch gekennzeichnet, daß diese Fraktionen, je nach ihrer Zusammensetzung, zwei oder mehr Entmischungselementen auf beiden Seiten oder auch dem betreffenden Entmischungselement selbst, derart zugeführt werden, daß die von einem Elemente einem zweiten Entmischungselemente zugeführte Gasmenge nahezu gleich der von dem zweiten Entmischungselemente dem ersten Elemente zugeführten Gasmenge, oder die den Entmischungselementen auf einer Seite eines bestimmten Entmischungselementes zugeführte Gasmenge nahezu gleich der den Entmischungselementen auf der andern Seite zugeführten Gasmenge ist.

2. Verfahren nach Anspruch 1, dadurch gekennzeichnet, daß der Widerstand des Weges des ersten Entmischungselementes zum zweiten dem Widerstand des Weges des zweiten Entmischungselementes zum ersten nahezu gleich ist.

3. Verfahren nach Anspruch 2, dadurch gekennzeichnet, daß der Widerstand des einen Weges praktisch von einer porösen Wand bedingt wird, während der Widerstand des andern Weges durch eine geeignete Wahl des Durchmessers oder der Länge der zu diesem Zwecke verwendeten Röhre dem Widerstand des ersten Weges ungefähr gleich gemacht wird.

January 27, 1944

Brig. Gen. L. R. Groves
P.O. Box 2610
Washington, D.C.

Dear Gen. Groves:

Major Furman has told us that in connection with the work we are doing for him we should cover possible enemy activities in every phase of our project, that is, the X-10, Y-12, and K-25 processes.

We have dismissed as too improbable to require investigation the possibility that the enemy may be engaged in the Y-12 process on a scale of military importance. We believe, however, that due to the fact that the enemy was considerably in advance of us in certain work of the K-25 type before the war, there is a high probability that if he is doing anything of military interest in our field, he is operating along this line.

In order to suggest to Major Furman appropriate leads for investigation, we would like to request that Dr. Karl Cohen of the Columbia group be authorized to visit us and discuss various methods of accomplishing our result by K-25 processes. Dr. Cohen in his work for Dr. Urey has had wide experience in investigating several kinds of such processes, some of which have been dropped as not promising but may have been developed by the enemy.

Would it be possible for you to authorize such a visit in the near future?

Yours sincerely,

Samuel K. Allison

Figure D.228: Samuel K. Allison to Leslie R. Groves. 27 January 1944. "[D]ue to the fact that the enemy was considerably in advance of us in certain work of the K-25 [gaseous diffusion enrichment] type before the war, there is a high probability that if he is doing anything of military interest in our field, he is operating along this line." [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]

Gustav Hertz. 1932. Ein Verfahren zur Trennung von gasförmigen Isotopengemischen und seiner Anwendung auf die Isotopen des Neons. [Process for the separation of gaseous mixtures of isotopes and its application to the isotopes of neon.] *Zeitschrift für Physik* 79:108–131, 700.

Das Verfahren benutzt die Diffusion durch eine poröse Wand ins Vakuum. Es ermöglicht die gleichzeitige Wirksamkeit einer großen Zahl von Diffusionszellen und damit eine weitgehende Entmischung eines Isotopengemisches in einem einzigen Arbeitsgang. Die ausgeführte Apparatur, welche 24 Pumpen und 48 Tonrohre enthält, ergibt bei einmaliger Anwendung auf die Isotopen des Neons in wenigen Stunden eine Änderung des Isotopenverhältnisses um nahezu den Faktor 8. Durch wiederholte Anwendung ist eine weitergehende Trennung möglich. Es werden Massenspektrogramme und optische Spektren von Neon-Isotopengemischen verschiedener Zusammensetzung reproduziert.

The process uses diffusion through a porous wall into a vacuum. It allows the simultaneous effectiveness of a large number of diffusion cells and thus extensive segregation of a mixture of isotopes in a single operation. The executed apparatus, which contains 24 pumps and 48 clay tubes, when applied once to the isotopes of neon, results in a change in the isotopic ratio by a factor of nearly 8 in a few hours. More extensive separation is possible by repeated application. Mass spectrograms and optical spectra of neon isotope mixtures of various compositions are reproduced.

Gustav Hertz. 1932. Ein Verfahren zur Trennung von gasförmigen Isotopengemischen. [A process for the separation of gaseous isotope mixtures.] *Naturwissenschaften* 20:493–494.

Gustav Hertz. 1933. Reindarstellung des schweren Wasserstoffisotops durch Diffusion. [Manufacture of Pure Heavy Hydrogen Isotope by Diffusion.] *Naturwissenschaften* 21:884–885.

H. Harmsen, Gustav Hertz, and Werner Schütze. 1934. Weitere Versuche zur Isotopentrennung. [Further experiments on isotope separation.] *Zeitschrift für Physik* 90:703–711.

Die Leistungsfähigkeit der früher beschriebenen Apparatur zur Trennung von gasförmigen Isotopengemischen ist durch Verdoppelung der Zahl der Trennungsglieder sowie durch Benutzung größerer Pumpen bei einem Teil der Trennungsglieder so weit erhöht worden, daß bereits durch einmalige Anwendung des Verfahrens aus normalem Neon das Isotop 22 praktisch rein hergestellt werden kann. Auch das schwere Wasserstoffisotop läßt sich mit Hilfe der Apparatur in großer Reinheit darstellen. Ausgehend von einem Wasserstoff, welcher etwa $1^{o}/_{oo}$ des schweren Isotops enthält, ergibt sich in 8 Stunden 1 cm^3 spektralreiner schwerer Wasserstoff von Atmosphärendruck.

The efficiency of the previously described apparatus for the separation of gaseous isotopic mixtures has been increased by doubling the number of separation elements and by using larger pumps for some of the separation elements to such an extent that the isotope 22 can be produced practically pure from normal neon just by using the process once. The heavy hydrogen isotope can also be produced in great purity with the aid of the apparatus. Starting from a hydrogen containing about $1^{o}/_{oo}$ of the heavy isotope, 1 cm^3 of spectrally pure heavy hydrogen of atmospheric pressure is obtained in 8 hours.

Gustav Hertz. 1934. Ein Verfahren zur Trennung von Isotopengemischen durch Diffusion in strömendem Quecksilberdampf. [Process for the separation of isotope mixtures by diffusion in flowing mercury vapour.] *Zeitschrift für Physik* 91:810–815.]

Das früher angegebene Verfahren zur Trennung von Isotopengemischen wird dadurch verbessert, daß an Stelle der Diffusion durch eine poröse Wand die Diffusion in strömendem Quecksilberdampf zur Trennung verwandt wird. Hierzu wird eine Diffusionspumpe besonderer Bauart benutzt, welche die Eigenschaft hat, aus einem Gasgemisch bevorzugt die schneller diffundierenden Bestandteile zu pumpen. Aus zwölf solchen Pumpen wird eine Apparatur zusammengesetzt, welche für die Neonisotopen eine Änderung des Isotopenverhältnisses um etwa den Faktor 10 ergibt.

The method described earlier for separating isotope mixtures is improved by using diffusion in flowing mercury vapor instead of diffusion through a porous wall. For this purpose, a diffusion pump of special design is used, which has the property of preferentially pumping the more rapidly diffusing components out of a gas mixture. An apparatus is assembled from twelve such pumps, which results in a change of the isotope ratio for the neon isotopes by a factor of about 10.

Hubert Krüger. 1939. Über die Anreicherung des N^{15}-Isotops und einige spektroskopische Untersuchungen am N^{15}. [About the Enrichment of the N^{15} Isotope and Some Spectroscopic Investigations of N^{15}.] *Zeitschrift für Physik* 111:467–474.

Mit einer 42 gliedrigen Hertzschen Isotopentrennungsapparatur konnten Anreicherungen des N^{15}-Isotops von N^{14}:N^{15}=4:1 erreicht werden.

With a 42-stage Hertz isotope separation apparatus, enrichments of the N^{15} isotope of N^{14}:N^{15}=4:1 could be achieved.

Pavel V. Oleynikov. 2000. German Scientists in the Soviet Atomic Project. *Nonproliferation Review* 7:2:1–30.

Gustav Hertz was probably the most eminent scientist among all the Germans who went to work in the Soviet Union. He received the Nobel Prize in physics in 1925 for his work with James Franck demonstrating the quantized nature of atomic excitation potentials. In 1932, he conducted the first experiments into separation of neon isotopes by the diffusion method. At the time of his transfer to the Soviet Union, he was the head of Siemens Research Laboratory. [...]

Hertz arrived at Sukhumi together with von Ardenne and was given a separate institute—Institute “G” at Agudzery. [...] The topics assigned to Institute “G” were:[114]

- separation of isotopes by diffusion in a flow of inert gas (leader—Gustav Hertz);
- development of a condensation pump (leader— Muellenpford); and
- development of a theory of stability and control of a diffusion cascade (leader—Heinz Barwich).

[...] German scientists substantially contributed to the Soviet’s efforts to design a membrane for gaseous diffusion technology. In early 1946, Laboratory No. 2 (now the Kurchatov Institute) issued a classified request for a proposal to design a flat membrane.[175] Fifteen organizations submitted their designs. The Moscow Combine of Hard Alloys (MKTS) won the competition. In their design, nickel powder was poured into a mold atop a vibrating table. After some vibration to compact the powder and level its surface, the tray was baked in an oven until the powder was partially melted and formed a ceramic-like porous plate. After the addition of some strengthening elements, the plate was turned into a membrane ready for use. After tests, however, it was found that nearly 10 percent of all pores in such a membrane would let any molecule go through (i.e., were too big to perform the separation function), and that the operating pressure of such membranes was 20 to 30 millimeters (mm) of mercury (Hg) column, a feature that would lead to large losses of electric power, a waste of compressor power, and extremely high requirements on the air-tightness of the machinery.

German groups in Institutes “A” and “G” joined the competition some time in 1947 and started to work on designs for tubular membranes that were expected to be more efficient. Peter Thiessen’s group in Institute “A” focused on a lattice-type filter: a nickel lattice with 10,000 holes per square centimeter was covered by fine-grain nickel carbonyl and baked in an oven. Afterwards, the mesh was bent and welded into tubes. It was discovered that Soviet industry at the time was unable to duct nickel wire finely enough to make the required lattice. For some time the necessary wire and the lattice were ordered from Berlin.[176] Although Peter Thiessen later received a Stalin Prize for his work in the area of gaseous diffusion, it is unlikely that he personally invented the membrane. Rudenko and Kruglov mention that a Dr. [Werner] Schütze received a Stalin Prize in 1948 for design of a diffusion membrane.[177]

Both German and Russian sources state that Thiessen’s design had an unpredictable nature and was more appropriate for a lab bench than mass production; Zavenyagin derided his process as “artisanship.”[178] Nickel carbonyl powder was manually sprayed on flat lattices and then these were pressed by rolls. Given the huge surface area of diffusion membranes, manual spraying was a real drawback. The need to do it manually disappeared only in 1952 when a way to automate this tedious process was found.[179]

The German group in Institute "G" was headed by a former pharmacist, Reinhold Reichmann. He was working on a mouthpiece type of membrane that could be extruded and would require no welding. Reichmann first experimented with copper and silver, then with nickel. Reichmann's solution clearly had its roots in his previous occupation—he mixed nickel with dimethylgloxin and then with a mild pain killer, clove pinks oil.[180] The mixture was then extruded and baked. Reichmann died soon after his discovery, and a Stalin Prize was awarded to him posthumously in 1948.[181]

Both types of tubular filters developed by the German teams, after tests in Laboratory No. 2, were approved for use in second-generation diffusion machines.[182] It was decided to send Thiessen's group to Plant No. 12 in Elektrostal, and Reichmann's group (headed then by V.N. Yeremin and his wife) to the MKTS. Beginning in 1949, these two plants started to manufacture all filters for diffusion machines.

The new filters could be used at pressures up to 50 mm of Hg column. This meant that—without any changes in the gaseous diffusion plant's design—its capacity could be increased by a factor of 2 or 2.5, provided its compressors could work at higher pressures. Tubular filters were first used in the second-generation diffusion machines that formed the basis of the second diffusion plant, the D-3 plant at Sverdlovsk-44.[183] In 1953, Zavenyagin decided that the production of diffusion filters should be transferred to the Sverdlovsk-44 site in the Urals.[184] [...]

At the NKVD's instruction, in late 1945 Hertz and his colleagues in Institute "G" started development of a control theory for diffusion cascades. Cascades connect a large number of individual diffusion stages in which the isotope of interest is gradually separated from the initial feed gas. Hertz and Barwich were calculating requirements for pumps in the diffusion cascades, and also acceptable losses of uranium hexafluoride due to corrosion in the cascades. Also, from theoretical calculations they determined percolation (i.e., a statistical description of a particle's path through a filter) in a membrane and the diameter of pores in a filter. In 1946, Barwich worked out a theory of natural stability of separation cascades that led to a reduction in the number of compressors in the design of the enrichment plant and a reduction in the time the material stayed inside the plant. [...]

In 1948, the first gaseous diffusion plant in the USSR, D-1, was put into operation. It contained 6,200 diffusion machines installed in 56 enrichment cascades.[185] The D-1 plant had problems.[186] Ball-bearings in compressors were made too precisely, without proper tolerances for thermal expansion, and quickly failed. Infusions of uranium hexafluoride into the plant were not leading to any product at the output. The situation was catastrophic. Among the luminaries brought in to help solve the problem in October 1948 were Gustav Hertz, Heinz Barwich, and Peter Thiessen.[187] Because they did not know the official name of the secret facility, the trio christened it "Kefirstadt" (now Sverdlovsk-44 or Novouralsk) after the "kefir" milk drink that they were given there every day for more than a month.[188]

The D-1 plant's greatest problem was corrosion. In the presence of water, uranium hexafluoride turned into tetrafluoride and stuck to the surfaces of the cascades as a powder. To fix this, all workshops were put under air hoods where they were supplied with dehumidified air. Also, nearly 5,000 leaky compressors were replaced in the plant. Peter Thiessen, with his co-worker from Sukhumi Prof. Karzhavin, proposed using a heated fluorine-air mixture to passivate (i.e., give a protective coating to) all internal surfaces of the cascades to reduce future corrosion by tetrafluoride.[189] [...]

The first awards for uranium enrichment technologies were presented in 1951 after the successful tests of a nuclear bomb containing uranium (the earlier Soviet test in 1949 involved a plutonium bomb).[191] Thiessen was awarded a first class Stalin Prize, while Hertz, Barwich, and their Russian colleague Krutkow received a second class award.[192]

[176] Russian respect for Germany and its industry was well-founded. Even in times of war Germany was able to produce products much superior to anything in the Soviet Union. See, for example, B. Chertok, *Rakety I Ljudi*, where he mentions that the Germans had used nearly 80 metals and alloys in their V-2 rocket, while Soviet industry was capable of producing less than 40.

[180] Clove pinks oil was used as a mild pain killer by dentists. It relieves pain when it evaporates.

[181] Albrecht, Heinemann-Grueder, and Wellmann, *Die Spezialisten*, p. 67.

[182] Amazingly, there was strong opposition to this decision. The Gorkiy machine plant that won the contract to manufacture the first-generation machines with flat filters was against the idea, while the design bureau from the Elektrosila plant in Leningrad, which was still trying to promote its designs, wanted to adopt the new technology. In his book, Sinjov openly speaks of "revenge by Gorkiy people." Even huge projects do not kill envy in people! See Sinjov, *Obogaschjonny uran dlja atomnogo oruzhija i energetiki*, p. 42.

3. Industrial contrib. without [outside] USSR

- most nickel wire mesh for use as a barrier backing for the gaseous diffusion plant by East German factories–altho reports: such prod. in Moscow area
- Re nickel wire for these screens, as well as looms for it, are also prod's of East German firms.
- apparently only EMIL JAEGER firm NEUSTADT/ORLA capable of making looms of the quality req'd in prod. of fine nickel wire mesh.

[...] by mid-1948, USSR had started prod. of the fine nickel wire mesh needed as backing for their barrier. This wire mesh is extremely difficult to produce, + only a few firms in the Soviet zone of Germany + apparently none in USSR, could make this product.

[Leftover wartime factories in Neustadt an der Orla, East Germany, were perfectly set up to make high-quality nickel membrane filters for gaseous diffusion uranium enrichment plants.

See pp. 3634–3638, 5052, 5055–5057. Manufacturing the filters was so difficult that even years after the war, Soviet plants could not make comparable items.

What exactly did these German factories do during the war? Did wartime Germany build gaseous diffusion uranium enrichment plants?

See also reports on large-scale production of nickel in Germany during the war (p. 4138).]

Ein Riese mit Fingerspitzengefühl: Drahtwebstuhl läuft in der Ausstellung "Aufbau West" auf Zollern [A Giant with Flair: Wire Loom Runs in the Exhibition "Development West" at Zollern]. LWL. 22 December 2005. https://www.lwl.org/pressemitteilungen/nr_mitteilung.php?urlID=15584

Teilweise demontiert und durch die DDR-Regierung enteignet, stand die Maschinenfabrik Emil Jäger im thüringischen Neustadt/Orla in der Nachkriegszeit faktisch vor dem Aus. Der Firmenchef floh 1948 in den Westen, um hier sein Familienunternehmen wieder aufzubauen. Eine solide Grundlage für den Neubeginn war nicht nur die Tatsache, dass ihm viele Fachkräfte aus Thüringen folgten, sondern vielmehr der glückliche Umstand, dass Jäger schon während des Krieges Sicherheitsverfilmungen seiner Maschinenpläne anfertigen lassen hatte. Neben dem Wissen im Kopf waren diese rund 1.500 Kleinbildaufnahmen das Fundament für den Neubeginn.

Für einen erfolgreichen Start im Westen sorgte 1948 das Angebot der "Westfälischen Union": Jäger sollte die Maschinen für die Neueinrichtung einer Drahtweberei in Hamm bauen. Das damals führende Unternehmen der deutschen Drahtindustrie stellte dafür Platz auf dem werkseigenen Gelände, Maschinen sowie Geld zur Verfügung. Am 1. Juli 1949 war der erste Drahtwebstuhl fertig. [...]

Platzmangel in Hamm sowie ein günstiges Angebot brachten Emil Jäger 1952 schließlich dazu, seinen Betrieb nach Münster zu verlagern. Hier nahm er in den zerstörten Hallen der ehemaligen Flugzeugfabrik Hansen die Produktion wieder auf und die Erfolgsgeschichte des Unternehmens ging weiter: Die 500. Maschine wurde im Mai 1956 fertiggestellt, die 1000. folgte im Frühjahr 1961. In den 1960er Jahren avancierte Emil Jäger bereits zum größten Hersteller der Welt.

Partially dismantled and expropriated by the GDR government, the Emil Jäger machine factory in Neustadt/Orla in Thuringia was effectively on the brink of extinction in the post-war period. The company boss fled to the West in 1948 to rebuild his family business here. A solid foundation for the new start was not only the fact that many skilled workers from Thuringia followed him, but rather the fortunate circumstance that Jäger had already had safety films made of his machine plans during the war. In addition to the knowledge in his head, these approximately 1,500 35mm photographs were the foundation for the new start.

In 1948, an offer from "Westfälische Union" ensured a successful start in the West: Jäger was to build the machines for the new establishment of a wire weaving mill in Hamm. The leading company in the German wire industry at the time provided space on its own premises, machines and money. On 1 July 1949, the first wire loom was ready. [...]

A lack of space in Hamm and a favorable offer finally led Emil Jäger to relocate his business to Münster in 1952. Here he resumed production in the destroyed halls of the former Hansen aircraft factory, and the company's success story continued: the 500th machine was completed in May 1956, followed by the 1000th in spring 1961. By the 1960s, Emil Jäger had already advanced to become the world's largest manufacturer.

1. [redacted] the following seven steps as the essential ones in reed manufacture:

   a. Calculating and setting the binding machines.

   b. Cleaning the reed material.

   c. Binding.

   d. Coiling and inserting the springs.

   e. Fixing and soldering the binding-wire and half-round wire.

   f. Grinding.

   g. Checking the spacing of the lamellae bands, and for the presence of tin between the lamellae.

2. As of mid-June 1951 there was no one at the Metallweberei Neustadt/Orla (VVB Tewa) who could perform the calculating and setting processes expertly or who could service the machines, nor was there anyone in the Drahtwebstuhlbau, Neustadt, who could do so. This situation has not yet been felt because the machines are still running on the calculations and settings made before the recent loss of qualified personnel. But real difficulty will begin when the settings must be changed for reeds of different caliber. As things now stand, there seem to be only two possibilities left to continue production: either to set the machines by trial and error, which is time-consuming and produces uncertain results, or to find an engineer who could work out a method.

3. The cleaning of the reed material is not a difficult operation and is carried out by grinders or spring workers, as they are available for this work.

SUPPLEMENT REPORT NO. [redacted]

[redacted]

1. In December 1951, the WMW Drahtwebstuhlbau, Neutstadt/Orla, formerly Emil Jaeger, delivered an unspecified number of DFL (Doppelt-Fein-Leicht) looms to Tewa Metallweberei Neustadt/Orla (Tewa-Neustadt).* About mid-January 1952, two of these looms were in operation. Tewa-Neustadt will put the other new looms into operation gradually.

2. The new Jaeger looms are heavier than the old-type (Eilhauer) looms.** They are believed to last longer and to perform more accurate weaving than the old looms. They also differ from the old looms in that a change has been made in the governors for the guiding of the meshes (Regulatoren fuer die Steuerung der Maschen). The governors used formerly were spring governors with threads on the countershaft of the warp roller (Federregulatoren mit Gewinde an der Vorlegswelle der Zettelwalze). This type of governor was introduced by Eilhauer. The new looms have brake governors (Bremsregulatoren), model DFM.

3. Jaeger now has under construction (January 1952) a series of twenty-five looms of the same type as those delivered to Tewa. Construction of these looms has just begun. They are being manufactured on Russian orders for delivery to Russia. [redacted], paragraph 5).

25X1A

4. In addition to the new-type looms mentioned above, by the end of 1951, Jaeger completed the construction of a new loom model which is to be tested at Tewa-Neustadt. The following points are considered its main improvements over the old models:

   a. whereas the old models used harnesses(Geschirre) suspended on rolls and guided from below by a draw gear (Zugvorrichtung), the new model has its harnesses fixed in guide rails (Fuehrungsschienen) on both sides of the loom; the harnesses are steered from below by push and pull rods (Stosstangen).

1. In January 1952, the Tewa Metallweberei Neustadt (Tewa-Neustadt), had a total of 64 looms in operation. Most of them were engaged in the production of nickel screen number 231. Unspecified numbers of them were also engaged in the production of:

   a. nickel screen number 300

   b. phosphor-bronze screen number 270 (English-inch system)

   c. phosphor-bronze screen number 270 (French-inch system).

   One loom was engaged in the production of perlon mesh to be used as parachute material. Perlon mesh production had begun in December 1951.

2. Production of phosphor-bronze screen at Tewa-Neustadt will be discontinued as soon as the wire now on the looms is completed into screen. From then on, the plant will produce fine nickel wire screen exclusively.

3. Two of an unspecified number of new looms, which the WMW Drahtwebstuhlbau Neustadt (formerly Emil Jaeger) delivered to Tewa-Neustadt a short time ago, are in operation. The other looms delivered by Jaeger will be put into operation later.

4. The production plan for fine nickel wire screen in 1952 calls for the operation of a total of 80 looms at Tewa-Neustadt. This figure includes twelve DFL looms obtained from Tewa-Raguhn shortly before the end of 1951 and the looms obtained from Jaeger. It is expected that two DFL looms belonging to Pabst und Kilian, Raguhn, will be transferred to Tewa-Neustadt in the near future.

5. Thirty expert women weavers were sent from Tewa-Raguhn to Neustadt in December 1951 to train Neustadt women in the art of fine weaving. The Raguhn women will stay in Neustadt until April 1952.

1. Engineer Heinz Schmidt, head of the Tewa-Neustadt reed plant, has developed a new-type reed with the outstanding advantage that it can be made without soldering the band steel lamellae to the reed frames (Bundschienen). This is done by putting small pieces of lamellae band steel between the upper and lower ends of each two successive reed lamellae, in order to keep them equidistant, and by screwing all reed lamellae tightly together with the aid of four screws 25 to 30 millimeters long which are applied at the upper and lower parts of both reed ends. A reed of this type with a length of 50 centimeters was made at the Zeiss plant in Jena, under Schmidt's supervision.

2. This reed has been on trial at the Tewa-Neustadt weaving plant for the last two months, making nickel wire screen No. 231 and results have been excellent. The screen made with this reed did not have one single wide space (Gasse) and also otherwise lived up to the specifications for nickel wire screen produced for the Russians.

3. It is, however, doubtful whether the same excellent results can be obtained by reeds of this type which are longer than 50 centimeters. This is the crucial question since the nickel wire screen for the Russians must be one or one and two-tenths meters wide. Upon Schmidt's request, the Zeiss plant started at the beginning of April 1952 to make a reed of the same type with a length of one meter.

Procédé de séparation, par diffusion, de substances difficilement séparables.

Société dite : AUERGESELLSCHAFT AKTIENGESELLSCHAFT résidant en Allemagne.

Demandé le 16 avril 1942, à 16h 40m, à Paris.
Délivré le 22 janvier 1943. — Publié le 21 avril 1943.
(Demande de brevet déposée en Allemagne le 21 septembre 1940. — Déclaration du déposant.)

On sait que les éléments chimiques ne sont pas à considérer comme des matières complètement uniformes, mais au contraire que la plupart des éléments se composent de plusieurs espèces d'atomes différentes, les espèces d'atomes appartenant à un élément se distinguant par leur poids atomique et non par leurs propriétés chimiques. On appelle isotopes les espèces d'atomes qui appartiennent au même élément, mais ont des poids atomiques différents. La séparation des isotopes les uns des autres pose un problème particulièrement difficile, parce qu'il n'y a pas de différences chimiques entre les isotopes à séparer et que, par suite, toutes les méthodes chimiques de séparation échouent. On a donc tenté de recourir à des méthodes physiques de séparation, dans lesquelles le poids atomique se manifeste de telle manière que l'on puisse escompter la différenciation des atomes de poids différents. Mais parmi tous les essais entrepris dans ce sens, la très grande majorité ont manqué leur but, une des premières raisons de ces échecs étant due au fait que les différences de poids atomiques des corps isotopes sont pour la plupart très faibles.

A maintes reprises, on a essayé de mettre à profit le fait qu'un atome plus léger doit posséder une vitesse de diffusion plus grande qu'un atome moins léger. On a donc fait diffuser à travers des membranes poreuses les espèces d'atomes étudiées en essayant de réaliser leur séparation par ce moyen. La majorité de ces essais n'ont toutefois pas réussi. Il a été trouvé, ces dernières années, un procédé par lequel on peut, dans de nombreux cas, exécuter une séparation d'isotopes avec une pleine réussite tout au moins pour des isotopes gazeux. Il s'agit du procédé par « thermo-diffusion » indiqué par Clusius. Mais le procédé en question, aussi bien que tous les autres procédés qui produisent pour le moins une certaine ségrégation des isotopes, se limitent généralement à des corps gazeux. Un inconvénient plus grave encore des procédés indiqués jusqu'à présent réside dans la grande complexité, le prix élevé et le manque de robustesse des appareils que nécessite leur mise en œuvre. A cela s'ajoute la très grande dépense d'énergie nécessaire pour la séparation d'une certaine quantité de matière, dans tous ces procédés. Dans quelques cas particuliers, on réussit à séparer jusqu'à un certain degré des paires d'isotopes déterminées, sans franchir le cadre d'un procédé de laboratoire, mais les

[881.316] — 2 —

procédés employés jusqu'à présent n'ont aucune chance d'être appliqués à l'échelle industrielle.

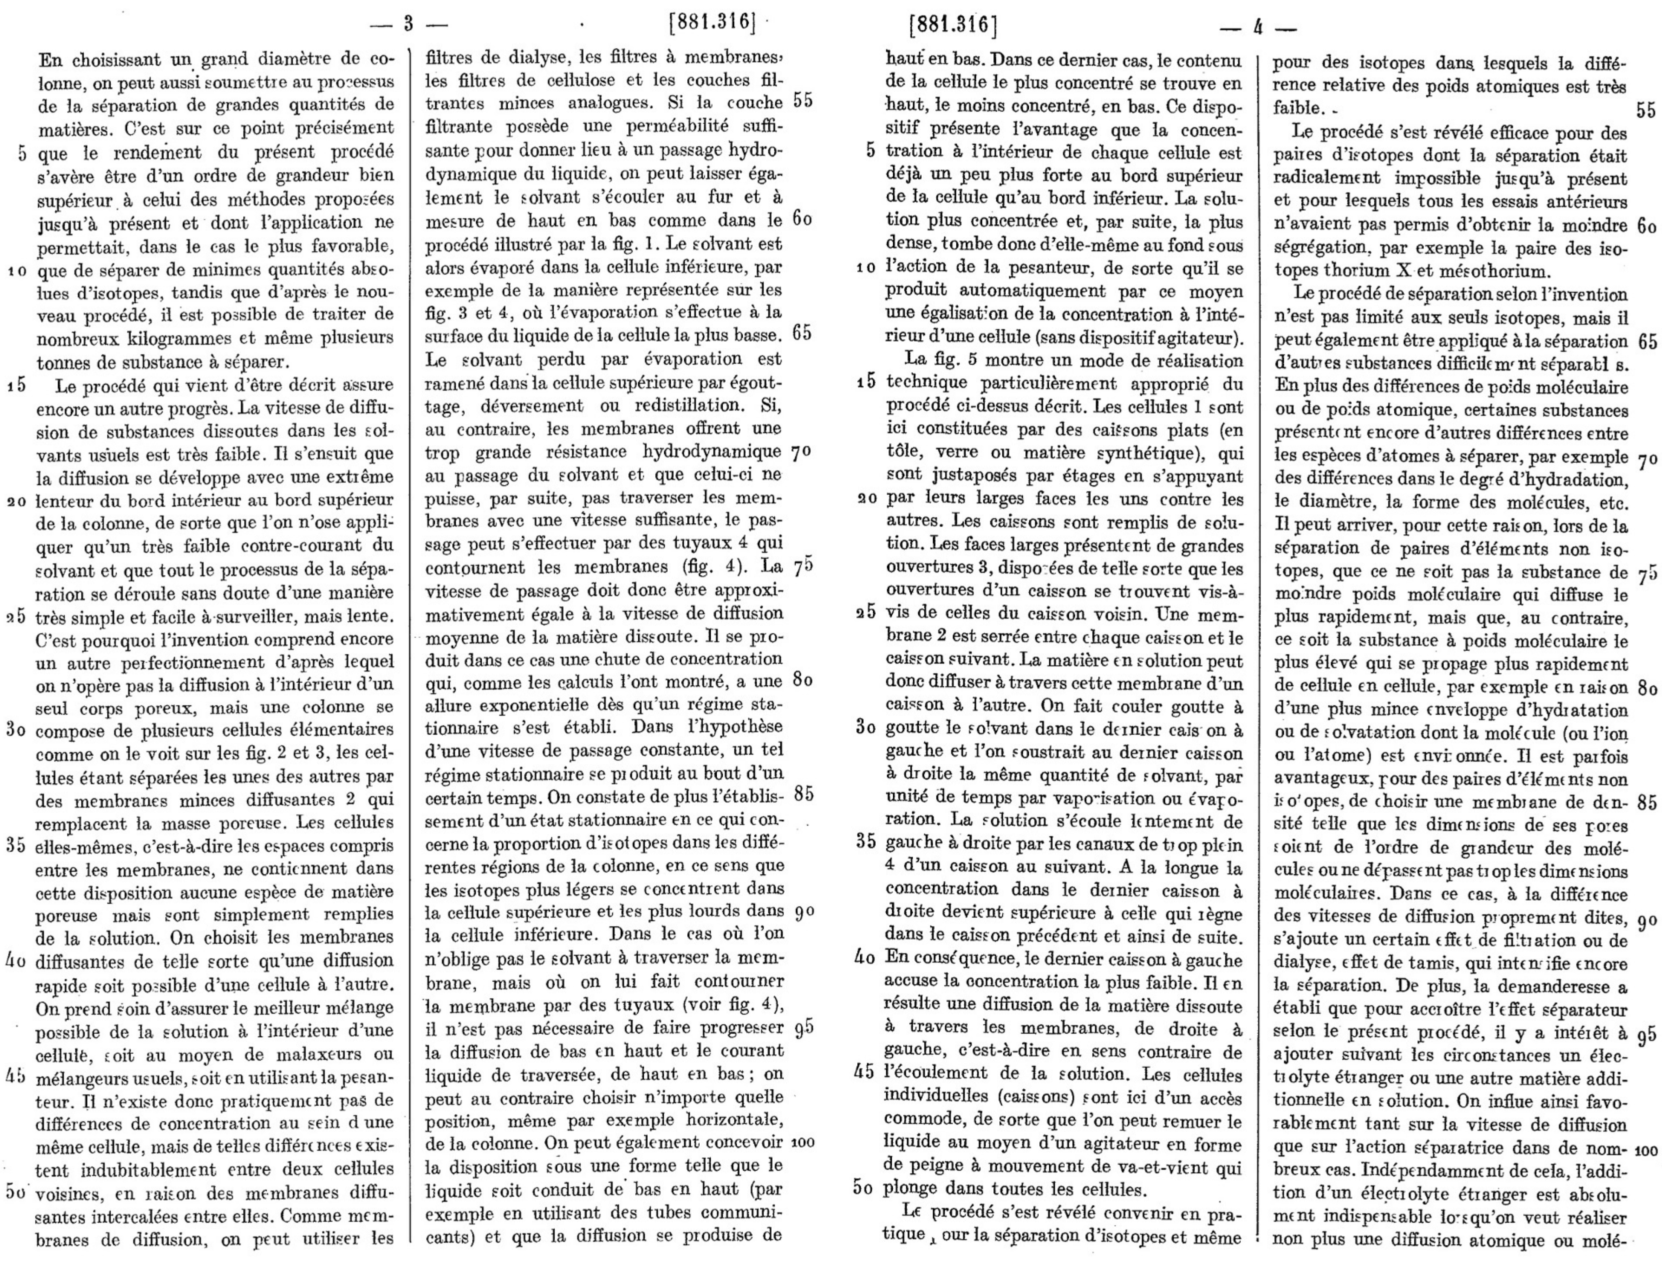
La présente invention concerne un procédé de séparation d'isotopes, exempt de tous les inconvénients caractéristiques des méthodes employées jusqu'à ce jour et qui, pour la première fois, permet de réaliser une séparation d'isotopes sur le plan industriel. Comme il s'agit ici d'un nouveau procédé physico-chimique de séparation, il est également applicable à la ségrégation d'autres substances difficilement séparables telles que, par exemple, les paires d'éléments formant des mélanges azéotropiques. En outre, le procédé n'est pas applicable uniquement aux gaz, mais encore particulièrement à des substances en solution. C'est là précisément qu'il convient d'apprécier l'importance particulière du nouveau procédé, car la séparation de substances dissoutes a une importance industrielle beaucoup plus grande que la séparation des seuls corps gazeux. En effet, les métaux notamment ne se trouvent pas en général normalement à l'état gazeux, tout au moins aux températures utilisables au laboratoire et en exploitation.

La description qui va suivre, en regard du dessin annexé, donné à titre d'exemple non limitatif, fera bien comprendre comment l'invention peut être réalisée, les particularités qui ressortent tant du dessin que du texte faisant, bien entendu, partie de celle-ci.

On décrira tout d'abord la forme de réalisation du procédé objet de l'invention qui est destinée à la séparation de substances à l'état dissous.

La fig. 1 sert à expliquer le procédé. Un cylindre 1, par exemple en tôle, est rempli d'une masse poreuse 2, telle que du sable, de la terre d'infusoires ou une masse céramique cohérente. La masse poreuse (telle que le sable) est noyée dans la solution des isotopes à séparer. A l'extrémité inférieure du cylindre, on évapore le solvant par la chaleur par ventilation ou par le vide, en prenant soin que l'évaporation soit suffisamment lente pour que le sel dissous ne risque pas de cristalliser. Par le haut, on verse du solvant frais goutte à goutte, en quantité égale à ce qui s'en évapore dans le bas. Il se passe alors le phénomène suivant : la solution se concentre au voisinage de la surface inférieure dans la mesure même où le solvant est évaporé à l'extrémité inférieure. Il se produit, par suite, une baisse de concentration de bas en haut et la matière dissoute commence à se diffuser de bas en haut. On a donc affaire ici à deux courants de sens contraires. L'un de ces courants est constitué par l'écoulement du solvant à travers la masse en direction descendante, l'autre est un courant de diffusion, en sens contraire, de la matière dissoute. Les atomes ou les ions ou molécules en solution, diffusent donc d'une manière ininterrompue de bas en haut, mais sans changer de place, car leur diffusion est continuellement compensée par le courant liquide s'écoulant à sa rencontre. (On pourrait illustrer les conditions régnant ici par l'exemple de l'écureuil dans sa cage rotative ; on sait que l'écureuil court continuellement sans changer de place, car la cage tourne en sens contraire). Grâce à la disposition adoptée, une diffusion ininterrompue et durable des isotopes s'établit de bas en haut et, par ce moyen, il se produit automatiquement une ségrégation, du fait que la partie basse de la solution s'enrichit peu à peu en isotope le plus lourd, la partie haute devenant plus riche en isotope le plus léger. Si l'on voulait entreprendre un fonctionnement de cette nature selon les méthodes usuelles de séparation, par exemple dans le genre de la cristallisation fractionnée, on serait conduit à employer des quantités de liquide exagérées et à surveiller et à préparer un très grand nombre de charges individuelles. Rien de tout cela n'est nécessaire pour le présent procédé. Tout le travail consiste à faire évaporer le solvant à l'extrémité inférieure de la colonne et à le faire retomber goutte à goutte à l'extrémité supérieure. Bien entendu, le dispositif doit comporter des appareils d'extraction, par exemple des tubulures d'aspiration qui permettent de prélever la solution de la colonne. Une telle colonne peut rester en service des mois, voire des années, sans nécessiter de frais importants en personnel de surveillance.

Figure D.235: Beginning in 1940, Auergesellschaft (probably Nikolaus Riehl) filed patents on an industrial-scale uranium enrichment process that combined aspects of gaseous thermal diffusion and what later became known as the PUREX process.



— 3 — [881.316]

En choisissant un grand diamètre de colonne, on peut aussi soumettre au processus de la séparation de grandes quantités de matières. C'est sur ce point précisément que le rendement du présent procédé s'avère être d'un ordre de grandeur bien supérieur à celui des méthodes proposées jusqu'à présent et dont l'application ne permettait, dans le cas le plus favorable, que de séparer de minimes quantités absolues d'isotopes, tandis que d'après le nouveau procédé, il est possible de traiter de nombreux kilogrammes et même plusieurs tonnes de substance à séparer.

Le procédé qui vient d'être décrit assure encore un autre progrès. La vitesse de diffusion de substances dissoutes dans les solvants usuels est très faible. Il s'ensuit que la diffusion se développe avec une extrême lenteur du bord intérieur au bord supérieur de la colonne, de sorte que l'on n'ose appliquer qu'un très faible contre-courant du solvant et que tout le processus de la séparation se déroule sans doute d'une manière très simple et facile à surveiller, mais lente. C'est pourquoi l'invention comprend encore un autre perfectionnement d'après lequel on n'opère pas la diffusion à l'intérieur d'un seul corps poreux, mais une colonne se compose de plusieurs cellules élémentaires comme on le voit sur les fig. 2 et 3, les cellules étant séparées les unes des autres par des membranes minces diffusantes 2 qui remplacent la masse poreuse. Les cellules elles-mêmes, c'est-à-dire les espaces compris entre les membranes, ne contiennent dans cette disposition aucune espèce de matière poreuse mais sont simplement remplies de la solution. On choisit les membranes diffusantes de telle sorte qu'une diffusion rapide soit possible d'une cellule à l'autre. On prend soin d'assurer le meilleur mélange possible de la solution à l'intérieur d'une cellule, soit au moyen de malaxeurs ou mélangeurs usuels, soit en utilisant la pesanteur. Il n'existe donc pratiquement pas de différences de concentration au sein d une même cellule, mais de telles différences existent indubitablement entre deux cellules voisines, en raison des membranes diffusantes intercalées entre elles. Comme membranes de diffusion, on peut utiliser les filtres de dialyse, les filtres à membranes, les filtres de cellulose et les couches filtrantes minces analogues. Si la couche filtrante possède une perméabilité suffisante pour donner lieu à un passage hydrodynamique du liquide, on peut laisser également le solvant s'écouler au fur et à mesure de haut en bas comme dans le procédé illustré par la fig. 1. Le solvant est alors évaporé dans la cellule inférieure, par exemple de la manière représentée sur les fig. 3 et 4, où l'évaporation s'effectue à la surface du liquide de la cellule la plus basse. Le solvant perdu par évaporation est ramené dans la cellule supérieure par égouttage, déversement ou redistillation. Si, au contraire, les membranes offrent une trop grande résistance hydrodynamique au passage du solvant et que celui-ci ne puisse, par suite, pas traverser les membranes avec une vitesse suffisante, le passage peut s'effectuer par des tuyaux 4 qui contournent les membranes (fig. 4). La vitesse de passage doit donc être approximativement égale à la vitesse de diffusion moyenne de la matière dissoute. Il se produit dans ce cas une chute de concentration qui, comme les calculs l'ont montré, a une allure exponentielle dès qu'un régime stationnaire s'est établi. Dans l'hypothèse d'une vitesse de passage constante, un tel régime stationnaire se produit au bout d'un certain temps. On constate de plus l'établissement d'un état stationnaire en ce qui concerne la proportion d'isotopes dans les différentes régions de la colonne, en ce sens que les isotopes plus légers se concentrent dans la cellule supérieure et les plus lourds dans la cellule inférieure. Dans le cas où l'on n'oblige pas le solvant à traverser la membrane, mais où on lui fait contourner la membrane par des tuyaux (voir fig. 4), il n'est pas nécessaire de faire progresser la diffusion de bas en haut et le courant liquide de traversée, de haut en bas ; on peut au contraire choisir n'importe quelle position, même par exemple horizontale, de la colonne. On peut également concevoir la disposition sous une forme telle que le liquide soit conduit de bas en haut (par exemple en utilisant des tubes communicants) et que la diffusion se produise de

[881.316] — 4 —

haut en bas. Dans ce dernier cas, le contenu de la cellule le plus concentré se trouve en haut, le moins concentré, en bas. Ce dispositif présente l'avantage que la concentration à l'intérieur de chaque cellule est déjà un peu plus forte au bord supérieur de la cellule qu'au bord inférieur. La solution plus concentrée et, par suite, la plus dense, tombe donc d'elle-même au fond sous l'action de la pesanteur, de sorte qu'il se produit automatiquement par ce moyen une égalisation de la concentration à l'intérieur d'une cellule (sans dispositif agitateur).

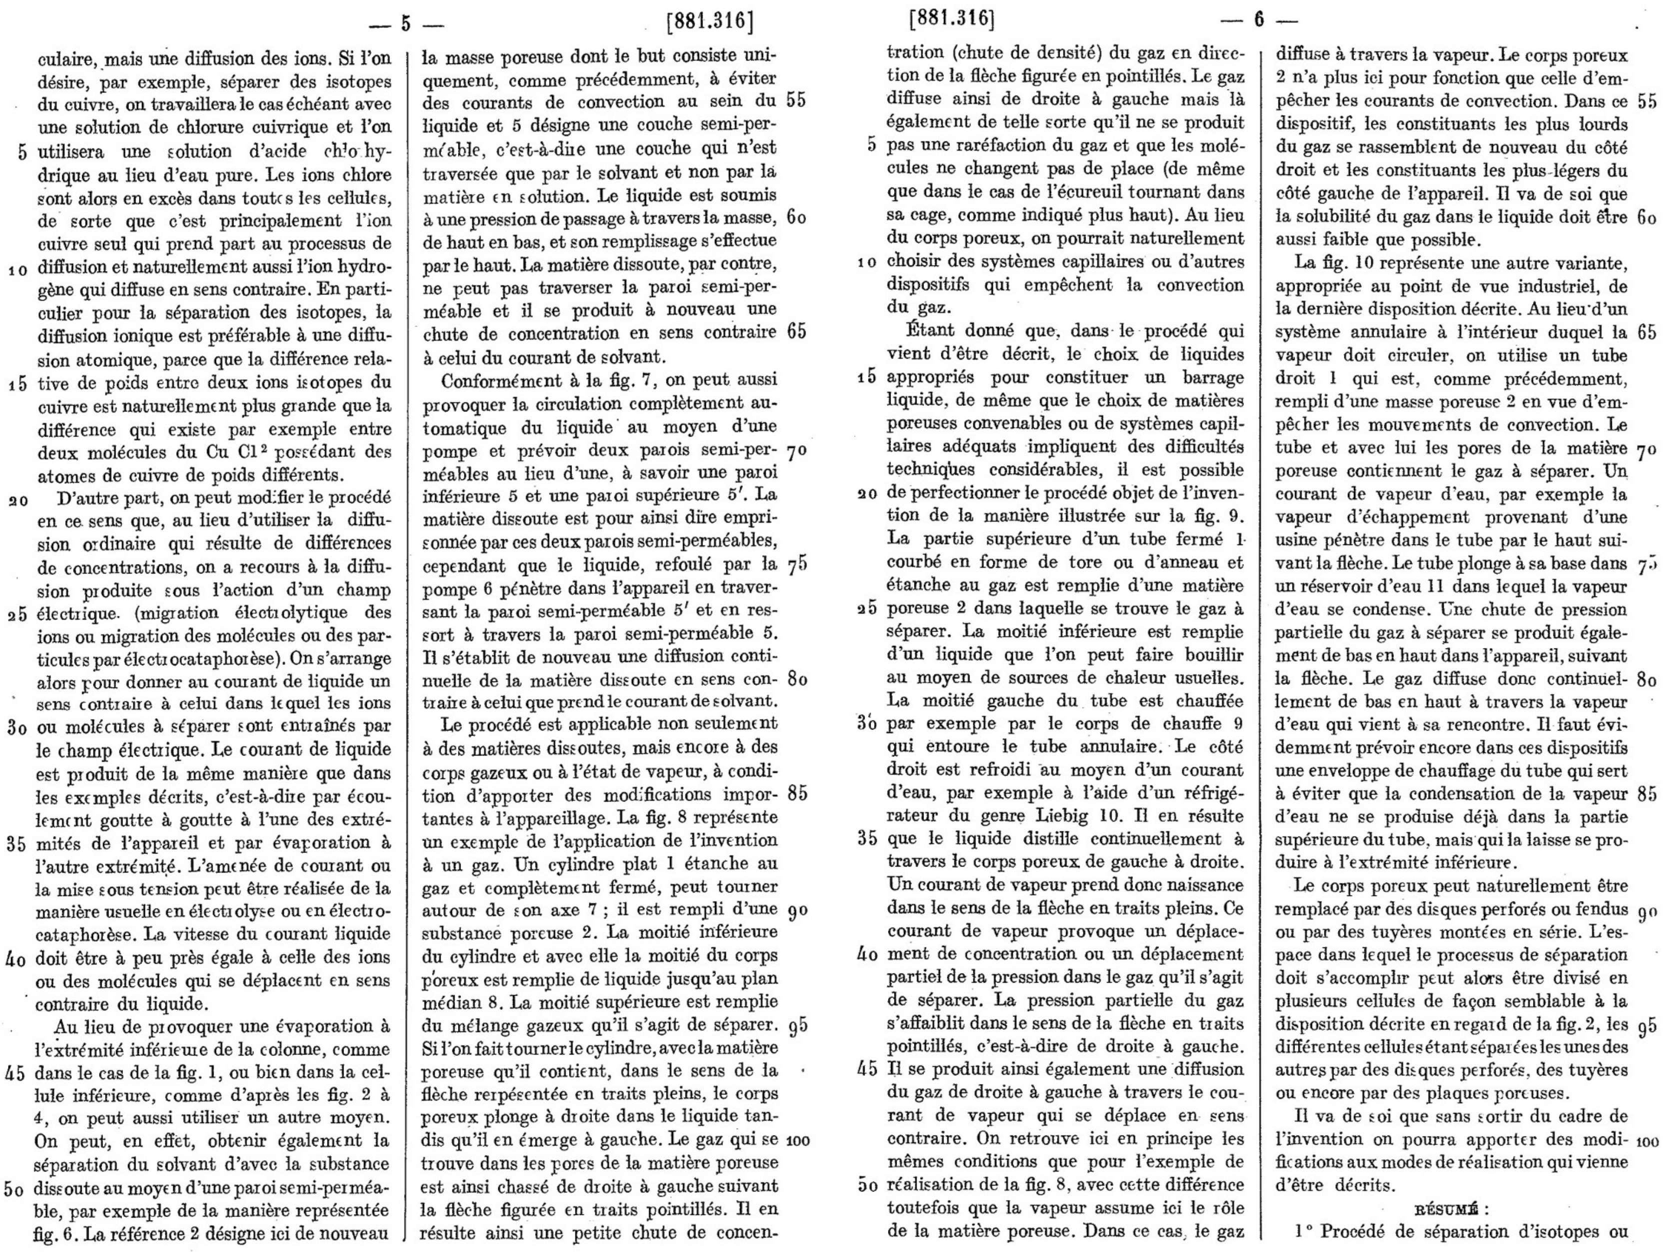
La fig. 5 montre un mode de réalisation technique particulièrement approprié du procédé ci-dessus décrit. Les cellules 1 sont ici constituées par des caissons plats (en tôle, verre ou matière synthétique), qui sont justaposés par étages en s'appuyant par leurs larges faces les uns contre les autres. Les caissons sont remplis de solution. Les faces larges présentent de grandes ouvertures 3, disposées de telle sorte que les ouvertures d'un caisson se trouvent vis-à-vis de celles du caisson voisin. Une membrane 2 est serrée entre chaque caisson et le caisson suivant. La matière en solution peut donc diffuser à travers cette membrane d'un caisson à l'autre. On fait couler goutte à goutte le solvant dans le dernier caisson à gauche et l'on soustrait au dernier caisson à droite la même quantité de solvant, par unité de temps par vaporisation ou évaporation. La solution s'écoule lentement de gauche à droite par les canaux de trop plein 4 d'un caisson au suivant. A la longue la concentration dans le dernier caisson à droite devient supérieure à celle qui règne dans le caisson précédent et ainsi de suite. En conséquence, le dernier caisson à gauche accuse la concentration la plus faible. Il en résulte une diffusion de la matière dissoute à travers les membranes, de droite à gauche, c'est-à-dire en sens contraire de l'écoulement de la solution. Les cellules individuelles (caissons) sont ici d'un accès commode, de sorte que l'on peut remuer le liquide au moyen d'un agitateur en forme de peigne à mouvement de va-et-vient qui plonge dans toutes les cellules.

Le procédé s'est révélé convenir en pratique pour la séparation d'isotopes et même pour des isotopes dans lesquels la différence relative des poids atomiques est très faible.

Le procédé s'est révélé efficace pour des paires d'isotopes dont la séparation était radicalement impossible jusqu'à présent et pour lesquels tous les essais antérieurs n'avaient pas permis d'obtenir la moindre ségrégation, par exemple la paire des isotopes thorium X et mésothorium.

Le procédé de séparation selon l'invention n'est pas limité aux seuls isotopes, mais il peut également être appliqué à la séparation d'autres substances difficilement séparables. En plus des différences de poids moléculaire ou de poids atomique, certaines substances présentent encore d'autres différences entre les espèces d'atomes à séparer, par exemple des différences dans le degré d'hydradation, le diamètre, la forme des molécules, etc. Il peut arriver, pour cette raison, lors de la séparation de paires d'éléments non isotopes, que ce ne soit pas la substance de moindre poids moléculaire qui diffuse le plus rapidement, mais que, au contraire, ce soit la substance à poids moléculaire le plus élevé qui se propage plus rapidement de cellule en cellule, par exemple en raison d'une plus mince enveloppe d'hydratation ou de solvatation dont la molécule (ou l'ion ou l'atome) est environnée. Il est parfois avantageux, pour des paires d'éléments non isotopes, de choisir une membrane de densité telle que les dimensions de ses pores soient de l'ordre de grandeur des molécules ou ne dépassent pas trop les dimensions moléculaires. Dans ce cas, à la différence des vitesses de diffusion proprement dites, s'ajoute un certain effet de filtration ou de dialyse, effet de tamis, qui intensifie encore la séparation. De plus, la demanderesse a établi que pour accroître l'effet séparateur selon le présent procédé, il y a intérêt à ajouter suivant les circonstances un électrolyte étranger ou une autre matière additionnelle en solution. On influe ainsi favorablement tant sur la vitesse de diffusion que sur l'action séparatrice dans de nombreux cas. Indépendamment de cela, l'addition d'un électrolyte étranger est absolument indispensable lorsqu'on veut réaliser non plus une diffusion atomique ou molé-

Figure D.236: Beginning in 1940, Auergesellschaft (probably Nikolaus Riehl) filed patents on an industrial-scale uranium enrichment process that combined aspects of gaseous thermal diffusion and what later became known as the PUREX process.



culaire, mais une diffusion des ions. Si l'on désire, par exemple, séparer des isotopes du cuivre, on travaillera le cas échéant avec une solution de chlorure cuivrique et l'on utilisera une solution d'acide chlorhydrique au lieu d'eau pure. Les ions chlore sont alors en excès dans toutes les cellules, de sorte que c'est principalement l'ion cuivre seul qui prend part au processus de diffusion et naturellement aussi l'ion hydrogène qui diffuse en sens contraire. En particulier pour la séparation des isotopes, la diffusion ionique est préférable à une diffusion atomique, parce que la différence relative de poids entre deux ions isotopes du cuivre est naturellement plus grande que la différence qui existe par exemple entre deux molécules du Cu Cl^2 possédant des atomes de cuivre de poids différents.

D'autre part, on peut modifier le procédé en ce sens que, au lieu d'utiliser la diffusion ordinaire qui résulte de différences de concentrations, on a recours à la diffusion produite sous l'action d'un champ électrique (migration électrolytique des ions ou migration des molécules ou des particules par électrocataphorèse). On s'arrange alors pour donner au courant de liquide un sens contraire à celui dans lequel les ions ou molécules à séparer sont entraînés par le champ électrique. Le courant de liquide est produit de la même manière que dans les exemples décrits, c'est-à-dire par écoulement goutte à goutte à l'une des extrémités de l'appareil et par évaporation à l'autre extrémité. L'amenée de courant ou la mise sous tension peut être réalisée de la manière usuelle en électrolyse ou en électrocataphorèse. La vitesse du courant liquide doit être à peu près égale à celle des ions ou des molécules qui se déplacent en sens contraire du liquide.

Au lieu de provoquer une évaporation à l'extrémité inférieure de la colonne, comme dans le cas de la fig. 1, ou bien dans la cellule inférieure, comme d'après les fig. 2 à 4, on peut aussi utiliser un autre moyen. On peut, en effet, obtenir également la séparation du solvant d'avec la substance dissoute au moyen d'une paroi semi-perméable, par exemple de la manière représentée fig. 6. La référence 2 désigne ici de nouveau la masse poreuse dont le but consiste uniquement, comme précédemment, à éviter des courants de convection au sein du liquide et 5 désigne une couche semi-perméable, c'est-à-dire une couche qui n'est traversée que par le solvant et non par la matière en solution. Le liquide est soumis à une pression de passage à travers la masse, de haut en bas, et son remplissage s'effectue par le haut. La matière dissoute, par contre, ne peut pas traverser la paroi semi-perméable et il se produit à nouveau une chute de concentration en sens contraire à celui du courant de solvant.

Conformément à la fig. 7, on peut aussi provoquer la circulation complètement automatique du liquide au moyen d'une pompe et prévoir deux parois semi-perméables au lieu d'une, à savoir une paroi inférieure 5 et une paroi supérieure 5'. La matière dissoute est pour ainsi dire emprisonnée par ces deux parois semi-perméables, cependant que le liquide, refoulé par la pompe 6 pénètre dans l'appareil en traversant la paroi semi-perméable 5' et en ressort à travers la paroi semi-perméable 5. Il s'établit de nouveau une diffusion continuelle de la matière dissoute en sens contraire à celui que prend le courant de solvant.

Le procédé est applicable non seulement à des matières dissoutes, mais encore à des corps gazeux ou à l'état de vapeur, à condition d'apporter des modifications importantes à l'appareillage. La fig. 8 représente un exemple de l'application de l'invention à un gaz. Un cylindre plat 1 étanche au gaz et complètement fermé, peut tourner autour de son axe 7 ; il est rempli d'une substance poreuse 2. La moitié inférieure du cylindre et avec elle la moitié du corps poreux est remplie de liquide jusqu'au plan médian 8. La moitié supérieure est remplie du mélange gazeux qu'il s'agit de séparer. Si l'on fait tourner le cylindre, avec la matière poreuse qu'il contient, dans le sens de la flèche rerpésentée en traits pleins, le corps poreux plonge à droite dans le liquide tandis qu'il en émerge à gauche. Le gaz qui se trouve dans les pores de la matière poreuse est ainsi chassé de droite à gauche suivant la flèche figurée en traits pointillés. Il en résulte ainsi une petite chute de concentration (chute de densité) du gaz en direction de la flèche figurée en pointillés. Le gaz diffuse ainsi de droite à gauche mais là également de telle sorte qu'il ne se produit pas une raréfaction du gaz et que les molécules ne changent pas de place (de même que dans le cas de l'écureuil tournant dans sa cage, comme indiqué plus haut). Au lieu du corps poreux, on pourrait naturellement choisir des systèmes capillaires ou d'autres dispositifs qui empêchent la convection du gaz.

Étant donné que, dans le procédé qui vient d'être décrit, le choix de liquides appropriés pour constituer un barrage liquide, de même que le choix de matières poreuses convenables ou de systèmes capillaires adéquats impliquent des difficultés techniques considérables, il est possible de perfectionner le procédé objet de l'invention de la manière illustrée sur la fig. 9. La partie supérieure d'un tube fermé 1 courbé en forme de tore ou d'anneau et étanche au gaz est remplie d'une matière poreuse 2 dans laquelle se trouve le gaz à séparer. La moitié inférieure est remplie d'un liquide que l'on peut faire bouillir au moyen de sources de chaleur usuelles. La moitié gauche du tube est chauffée par exemple par le corps de chauffe 9 qui entoure le tube annulaire. Le côté droit est refroidi au moyen d'un courant d'eau, par exemple à l'aide d'un réfrigérateur du genre Liebig 10. Il en résulte que le liquide distille continuellement à travers le corps poreux de gauche à droite. Un courant de vapeur prend donc naissance dans le sens de la flèche en traits pleins. Ce courant de vapeur provoque un déplacement de concentration ou un déplacement partiel de la pression dans le gaz qu'il s'agit de séparer. La pression partielle du gaz s'affaiblit dans le sens de la flèche en traits pointillés, c'est-à-dire de droite à gauche. Il se produit ainsi également une diffusion du gaz de droite à gauche à travers le courant de vapeur qui se déplace en sens contraire. On retrouve ici en principe les mêmes conditions que pour l'exemple de réalisation de la fig. 8, avec cette différence toutefois que la vapeur assume ici le rôle de la matière poreuse. Dans ce cas, le gaz diffuse à travers la vapeur. Le corps poreux 2 n'a plus ici pour fonction que celle d'empêcher les courants de convection. Dans ce dispositif, les constituants les plus lourds du gaz se rassemblent de nouveau du côté droit et les constituants les plus légers du côté gauche de l'appareil. Il va de soi que la solubilité du gaz dans le liquide doit être aussi faible que possible.

La fig. 10 représente une autre variante, appropriée au point de vue industriel, de la dernière disposition décrite. Au lieu d'un système annulaire à l'intérieur duquel la vapeur doit circuler, on utilise un tube droit 1 qui est, comme précédemment, rempli d'une masse poreuse 2 en vue d'empêcher les mouvements de convection. Le tube et avec lui les pores de la matière poreuse contiennent le gaz à séparer. Un courant de vapeur d'eau, par exemple la vapeur d'échappement provenant d'une usine pénètre dans le tube par le haut suivant la flèche. Le tube plonge à sa base dans un réservoir d'eau 11 dans lequel la vapeur d'eau se condense. Une chute de pression partielle du gaz à séparer se produit également de bas en haut dans l'appareil, suivant la flèche. Le gaz diffuse donc continuellement de bas en haut à travers la vapeur d'eau qui vient à sa rencontre. Il faut évidemment prévoir encore dans ces dispositifs une enveloppe de chauffage du tube qui sert à éviter que la condensation de la vapeur d'eau ne se produise déjà dans la partie supérieure du tube, mais qui la laisse se produire à l'extrémité inférieure.

Le corps poreux peut naturellement être remplacé par des disques perforés ou fendus ou par des tuyères montées en série. L'espace dans lequel le processus de séparation doit s'accomplir peut alors être divisé en plusieurs cellules de façon semblable à la disposition décrite en regard de la fig. 2, les différentes cellules étant séparées les unes des autres par des disques perforés, des tuyères ou encore par des plaques poreuses.

Il va de soi que sans sortir du cadre de l'invention on pourra apporter des modifications aux modes de réalisation qui vienne d'être décrits.

RÉSUMÉ :

1° Procédé de séparation d'isotopes ou

de mélanges de matières difficilement séparables, caractérisé par le fait que le mélange de matières est réparti sous forme de solution ou de gaz dans un corps intermédiaire, par exemple un solvant, une vapeur ou un corps poreux et est placé dans un réservoir de manière à ne pas pouvoir s'en échapper et que le corps intermédiaire précité est amené d'un côté dans l'espace fermé, le cas échéant, par un liquide de barrage et en est évacué de l'autre côté, de telle sorte qu'il se produit une chute de concentration du mélange de matières qui est dirigée en sens contraire au mouvement du corps intermédiaire ;

2° Appareil permettant la mise en œuvre du procédé spécifié sous 1°, caractérisé par le fait que la solution du mélange de matières se trouve à l'intérieur d'une colonne de matière poreuse entourée d'une enveloppe fixe et qu'il est prévu des moyens susceptibles d'évaporer le solvant à une extrémité de la colonne et de ramener la même quantité de solvant à l'autre extrémité de cette colonne ;

3° Appareil permettant la mise en œuvre du procédé spécifié sous 1°, caractérisé par le fait que la solution du mélange de matières à séparer est placée dans plusieurs cellules séparées les unes des autres par des membranes et l'on prévoit des moyens pour évaporer le solvant de la dernière cellule et pour en ramener la même quantité dans la première cellule, appareil pouvant présenter, en outre les particularités suivantes prises séparément ou en combinaison :

a. Les cellules connectées les unes à la suite des autres communiquent entre elles par des tuyauteries de dérivation ou de trop-plein ;

b. La série des cellules se compose de bassins étagés les uns par rapport aux autres, dont les parois adjacentes sont perforées et séparées entre elles par des membranes.

4° Variantes de l'appareil spécifié sous 2° selon lesquelles :

a. La colonne de matières poreuses est fermée à l'une de ses extrémités par une membrane semi-perméable ;

b. La colonne est limitée à chacune de ses extrémités par une membrane semi-perméable et une pompe refoule vers l'extrémité d'entrée le solvant qui est évacué par l'autre extrémité de la colonne ;

5° Appareil permettant la mise en œuvre du procédé spécifié sous 1° et comportant un cylindre creux horizontal fermé de toutes parts, susceptible de tourner autour de son axe et dont le volume intérieur est rempli d'une matière poreuse, la moitié supérieure du cylindre contenant le mélange gazeux à séparer, tandis que sa moitié inférieure est remplie d'un liquide de barrage.

6° Appareil permettant la mise en œuvre du procédé spécifié sous 1°, constitué par un tube annulaire fermé à ses extrémités et ayant un axe horizontal, tube rempli dans sa moitié inférieure d'un liquide de barrage et, dans sa moitié supérieure, du mélange gazeux à séparer qui peut être occlus dans un corps poreux, une partie du tube annulaire contenant le liquide étant pourvue d'un dispositif de chauffage et l'autre partie, d'un système réfrigérant.

7° Appareil permettant la mise en œuvre du procédé spécifié sous 1°, caractérisé par un cylindre vertical rempli d'une substance poreuse contenant elle-même le mélange gazeux à séparer, cylindre chauffé par l'extérieur et dont l'extrémité inférieure plonge dans un liquide d'arrêt, son extrémité supérieure étant raccordée à une conduite d'admission de vapeur.

1RE ADDITION
AU BREVET D'INVENTION

N° 881.316

Gr. 14. — Cl. 6. N° 53.405

Procédé de séparation, par diffusion, de matières difficilement séparables.

Société dite : AUERGESELLSCHAFT AKTIENGESELLSCHAFT résidant en Allemagne.
(Brevet principal pris le 16 avril 1942.)

Demandée le 17 avril 1942, à 14h 40m, à Paris.
Délivrée le 4 juin 1945. — Publiée le 10 janvier 1946.
(Demande de brevet additionnel déposée en Allemagne le 17 avril 1941. — Déclaration du déposant.)

Dans le brevet principal, il a été décrit notamment un procédé de séparation de mélanges gazeux difficilement séparables, selon lequel on provoque une diffusion continue du mélange gazeux d'une cellule dans l'autre, à travers des parois poreuses; dans ce but, à l'une des extrémités de la série de cellules, les cellules peuvent plonger successivement dans un liquide, tandis qu'elles sont soulevées hors de ce liquide à l'autre extrémité. Par ce moyen, il se produit une chute de pression du gaz le long de la série de cellules, ce qui provoque une diffusion permanente dans une direction.

La présente addition concerne un autre mode de réalisation de cette invention, qui offre d'importants avantages au point de vue de l'appareillage, notamment de la facilité de réalisation et de la sécurité de service de l'installation.

La description qui va suivre, en regard du dessin annexé, donné à titre d'exemple non limitatif, fera bien comprendre comment l'invention peut être réalisée, les particularités qui ressortent tant du dessin que du texte faisant, bien entendu, partie de celle-ci.

La fig. 1 est une coupe schématique servant à illustrer un premier exemple de réalisation.

Dans une enveloppe tubulaire cylindrique 1 fermée aux deux bouts ,un deuxième tube 2 peut monter et descendre à la manière d'un piston. Le tube 2 est subdivisé par plusieurs membranes poreuses 3 en compartiments distincts. La tige de commande 4 sert à imprimer au tube 2 un mouvement de va-et-vient vertical dans l'enveloppe tubulaire 1.

Quant la tige de commande et le tube 2 avec les membranes qui y son tdisposées, se déplacent vers le haut, par exemple, l'air est obligé de pénétrer de l'espace supérieur 5 dans la cellule voisine (cellule 6), par diffusion à travers les membranes. Il en résulte une surpression dans la cellule 6, de sorte qu'une nouvelle phase de diffusion se produit à travers la membrane suivante, dans la cellule 7 et ainsi de suite jusqu'à ce que la pression se soit à nouveau égalisée dans toutes les cellules et qu'il ne se trouve plus de traces d'air dans l'espace 5. Dans cet état, la membrane située le plus haut s'applique contre le couvercle de fermeture inférieur 10 de l'enveloppe tubulaire 1.

La course de translation suivante s'effectue en sens contraire : la tige de commande redescend. Il en résulte une surpression dans l'espace 8 de l'extrémité inférieure de l'enveloppe. A l'extrémité opposée, c'est-à-dire dans l'espace 5, on constate une dépression correspondante. La chute de pression du gaz est maintenant dirigée de bas en haut. Les membranes poreuses sont établies en même temps sous la forme de soupapes de retenue, autrement dit ces membranes, ou leur périphérie, reposent librement sur les anneaux 11, reliés solidairement au tube 2. Lors de la course descendante de la tige et du tube 2, les membranes se soulèvent, de sorte que l'égalisation de pression n'est plus provoquée par diffusion, mais par un écoulement ordinaire du mélange gazeux qui passe de la chambre inférieure dans la cellule située immédiatement au-dessus. Si l'on répète constamment les courses de montée et de descente, cela signifie que le gaz est sollicité, toujours à nouveau, à diffuser de haut en bas, de la cellule supérieure dans la cellule inférieure la plus proche. Ce processus peut être renouvelé aussi souvent qu'on le désire. Finalement, la fraction de mélange qui diffuse le plus facilement se rassemble dans la cellule inférieure, la fraction diffusant plus difficilement, dans la cellule supérieure.

La fig. 2 est une coupe schématique d'une variante, qui facilite mieux encore la mise en œuvre du procédé sur le plan industriel. On voit en 1, comme précédemment, un tube hermétiquement fermé à l'air. Des membranes de diffusion 3 sont fixées dans ce tube, de sorte que la totalité du tube est partagée en une série de cellules élémentaires. On a prévu en outre, d'une cellule à l'autre, des conduites de dérivation 12 qui peuvent être ouvertes ou fermées à l'aide des robinets ou soupapes 13. Une pompe 14 à piston, à membrane ou d'un autre type est disposée à la partie inférieure du tube 1. Sur le dessin, on a figuré en 14 une pompe à piston.

Quand l'appareil est en service, le piston monte et descend alternativement, ce qui produit tantôt une surpression, tantôt une dépression dans la cellule extrême inférieure. Lors de la course ascendante du piston, c'est une surpression qui est engendrée et le mélange gazeux doit diffuser à travers les membranes poreuses fixes, vers le haut, de cellule en cellule. Les robinets 13 des conduites de dérivation 12 sont fermés pendant la course ascendante du piston 14.

Au début de la course descendante du piston, on ouvre les robinets ou soupapes 13, ce qui peut être réalisé, par exemple, au moyen d'une barre d'accouplement ou d'une manière semblable connue. Lorsque le piston continue à descendre, il ne se produit par exemple, aucune diffusion du gaz de haut en bas à travers les membranes 3, mais le gaz revient en arrière dans chaque cellule inférieure voisine, en passant par les conduites de dérivation 12.

On obtient donc ici le même résultat final que dans le dispositif de la fig. 1, à savoir une diffusion sans cesse renouvelée du mélange gazeux, de bas en haut. Ce phénomène de diffusion se répète aussi souvent que le mouvement alternativement montant et descendant du piston. Les constituants du mélange gazeux qui diffusent le plus facilement se concentrent, dans ce cas, dans la cellule supérieure, les constituants les plus difficiles à diffuser, dans la cellule inférieure. On voit en 15 les tubulures d'évacuation ou les raccords à manomètres et appareils similaires.

L'appareil est naturellement susceptible de fonctioner aussi en régime continu, à condition de faire arriver par la tubulure intermédiaire le mélange gazeux à séparer, et de prélever ou d'extraire par la tubulure supérieure et la tubulure inférieure les mélanges qui se sont enrichis en constituants plus légers ou plus lourds. La différence essentielle de la disposition de la fig. 2 par rapport à celle de la fig. 1 consiste en ce que les déplacements alternatifs du gaz sont obtenus au moyen d'une seule pompe, c'est-à-dire d'une manière très simple aux points de vue constructif et technique.

Il va de soi que, sans sortir du cadre de la présente invention, on pourra apporter des modifications aux modes de réalisation qui viennent d'être décrits.

RÉSUMÉ

Mode de réalisation du procédé de séparation de mélanges gazeux difficilement séparables décrit dans le brevet principal, selon lequel on provoque tout d'abord une surpression à l'une des extrémités d'une colonne comportant des cellules remplies du mélange gazeux et séparées les unes des autres par des couches poreuses, de sorte qu'il s'établit une égalisation de pression de cellule en cellule par suite de la diffusion à travers les parois poreuses, puis on engendre une dépression à la même extrémité de la colonne, de telle sorte que l'égalisation des pressions s'établisse en sens contraire, non par diffusion mais par un écoulement ordinaire par des robinets ou soupapes qui s'ouvrent à cet effet, les deux phases se répétant alternativement aussi souvent qu'il peut être nécessaire.

2E ADDITION
AU BREVET D'INVENTION
N° 881.316

Gr. 14. — Cl. 6. N° 53.635

Procédé de séparation, par diffusion, de substances difficilement séparables.

Société dite : AUERGESELLSCHAFT AKTIENGESELLSCHAFT résidant en Allemagne.
(Brevet principal pris le 16 avril 1942.)

Demandée le 25 avril 1944, à 16^h 41^m, à Paris.
Délivrée le 18 février 1946. — Publiée le 21 juin 1946.
1re addition n° 53.405.

Le brevet principal concerne un procédé selon lequel on fait diffuser une substance dissoute ou une paire d'éléments en dissolution à travers des masses ou des membranes poreuses, mais en évitant un équilibre complet de la concentration de cette solution par le fait que l'on entretient un courant du solvant en sens contraire de celui de la diffusion. Par ce moyen on parvient à séparer les uns des autres les constituants dissous, d'une manière particulièrement favorable, qui n'était pas réalisable par la méthode de diffusion ordinaire. Afin d'entretenir le contre-courant du solvant, dont il vient d'être question, il faut verser continuellement du solvant frais à l'extrémité réceptrice ou à l'entrée du dispositif tandis que, à son autre extrémité, le solvant est constamment vaporisé, c'est-à-dire que la solution doit être reconcentrée. Cette vaporisation continue du solvant à une extrémité de l'appareil soulève des difficultés. Si l'on chauffe d'une manière quelconque la solution à cette extrémité de l'appareil, il se produit facilement, à cause du chauffage, des détériorations des membranes de diffusion employées. De plus, le chauffage donne lieu à des réactions indésirables entre, d'une part, le solvant ou les substances dissoutes et, d'autre part, les parois de l'appareil. Si l'on chauffe donc la solution de la manière habituelle, on est très limité dans le choix de la matière constitutive pour l'appareil, parce qu'il existe relativement peu de matériaux de construction qui gardent leur résistance à la majorité des réactifs, par exemple à la température d'ébullition de l'eau. Mais les membranes qui entrent en ligne de compte pour ce procédé, notamment celles constituées par de la cellulose régénérée, sont particulièrement sensibles à un chauffage. Or, de telles couches délicates, en cellulose ou analogues, se sont précisément comportées d'une façon très avantageuse pour le procédé en question.

Selon la présente invention, on remédie à cette difficulté par le fait que dans la partie de l'appareil conforme au brevet principal, dans laquelle doit s'effectuer la vaporisation du liquide, on introduit à une certaine distance du fond du récipient, un corps de verre creux à parois doubles, entre lesquelles règne le vide, corps dans l'intérieur duquel le liquide est chauffé d'une manière connue, par exemple au moyen d'un thermo-plongeur. Le corps creux

[53.635/881.316] — 2 —

peut être cylindrique et comporter à son extrémité inférieure, des pieds qui le maintiennent écarté du fond du récipient, dans lequel se trouve la solution à vaporiser.

On obtient par ce moyen qu'une fraction de la solution à vaporiser peut être chauffée jusqu'au point d'ébullition et, par suite, rapidement vaporisée, mais que les autres parties de la solution qui sont en contact avec les parois de l'appareil et avec les membranes de diffusion, restent froides. Le liquide vaporisé peut alors être reconduit à l'entrée de l'appareil, le cas échéant, à travers un réfrigérant.

La description qui va suivre, en regard du dessin annexé, donné à titre d'exemple non limitatif, fera bien comprendre comment l'invention peut être réalisée, les particularités qui ressortent tant du dessin que du texte faisant, bien entendu, partie de ladite invention.

Le dessin représente, à titre d'exemple pratique, la manière d'appliquer le perfectionnement ci-dessus décrit à l'appareil objet du brevet principal. Il montre la forme de réalisation d'appareil correspondant à la fig. 5 du brevet principal, dans laquelle l'ensemble du dispositif de diffusion se compose d'une série de cellules, séparées les unes des autres par des membranes diffusantes 2. Dans la dernière cellule doit s'opérer continuellement une vaporisation du solvant. La première cellule doit recevoir continuellement la même quantité de liquide solvant. Le courant de liquide va donc de la première à la dernière cellule, le courant de diffusion passe en sens contraire.

Sur le dessin, les cellules sont désignées par la référence 1. Les membranes de diffusion 2 sont serrées entre les parois des cellules 1 qui sont appliquées l'une contre la suivante et pourvues d'ouvertures 3. Dans la dernière cellule à droite se trouve, au sein du liquide, le tube 12, à vide entre ses parois, qui est maintenu écarté du fond du récipient 1, par exemple au moyen de pieds de support 13. Un corps de chauffe 14, avantageusement constitué par un thermo-plongeur ordinaire, est immergé à l'intérieur du tube 12 dans le liquide entouré par ce tube 12 et il provoque sa vaporisation. Les vapeurs sont emmenées par une conduite latérale 15, vers un réfrigérant 16 où elles se condensent et d'où le produit de cette condensation est ramené à la première cellule.

RÉSUMÉ :

1° Appareil permettant la mise en œuvre du procédé de séparation d'isotopes ou de mélanges de matières difficilement séparables spécifié dans le brevet principal, appareil dans la dernière cellule duquel (dans le sens du courant de solvant) est introduit, à une certaine distance du fond, un corps de verre creux entre les parois doubles duquel règne le vide et à l'intérieur duquel le liquide est chauffé et vaporisé d'une manière connue en soi, par exemple au moyen d'un thermo-plongeur;

2° Forme de réalisation de l'appareil spécifié sous 1°, dans laquelle on prévoit des moyens pour réintégrer dans le circuit le liquide vaporisé.

Mr. Philip Morrison
Metallurgical Laboratories
University of Chicago
Chicago, Illinois

Dear Morrison,

I made a survey of the Physics and Chemistry libraries which are the only ones which I feel competent to deal with. The following is a list of foreign journals to which I have access in these libraries:

- Physikalische Zeitschrift
- Zeitschrift fur Physik
- Annalen der Physik
- Die Chemische Technik
- Chemiker-Zeitung
- Die Chemie
- Die Chemische Industrie
- Chemische Zentralblatt
- Berichte d. Deutschen Chem. Ges.
- Kolloid Zeitschrift
- Z.f. Elektrochemie
- Z. physik. Chemie (A and B)
- Z. anal. Chemie
- Z. anorg. Chemie
- Bulletin de la Societe Chimique
- J.f. praktische Chemie
- Biochemische Zeitschrift
- Annalen der Chemie
- Brennstoff-Chemie

You will notice that I am lacking in Naturwissenschaften, Physikalische Berichte, and French physics journals. In general, our Chemistry Library is much better than the Physics Library in its efforts to secure foreign material.

2 ITEMS for Summary (P)

(Looking through some Chemische Zentralblatt which have just come in,) I found two references from French scientific journals on the possibilities of nuclear chain reactions and on element 94. (These are: (Constantin Bedreag "Position of Transuranic 93-94 in the natural system of elements." C.r. 215, 537 (1942); and Augustin Boutaric, "Nuclear Chemistry" Rev. sci. 80, 326 (1942).) (The first half of the Zentralblatt for 1943 came back from the bindery and) I found the following patent: Auergesellschaft, Berlin "Separation of Difficultly-Separable Gas Mixtures by Diffusion". At one end of a column containing cells separated from one another by porous layers and filled with the gaseous mixture an over-pressure is applied, so that pressure equalization takes place from cell to cell by diffusion. Next, at the

Letter to P. Morrison -2- 4-26-44.

same end of the column a low pressure is applied, and pressure equalization takes place in the opposite direction not by diffusion but by ordinary flow through automatically-opening valves. The two operations are repeated alternately as long as necessary. (Belgian patent 445,427 of 2-5-42, abstract published 20-3-43, German Priority 17-4-41.) I think this is extremely interesting as it is the first evidence of German interest in the diffusion method and also because of its tie-up with Auer.

I also picked up a reference to an article by Werner Kuhn and Hans Kuhn which was sent in from Basel on 2-8-43 and published in the Helvetica Chimica Acta on "The question of the rolling up of long chain molecules in flowing liquids".

I have not had much time to work on the plant descriptions, but I hope to be able to do them shortly. I will write as soon as I have anything.

Sincerely yours,

Karl Cohen

Summary of Information

Two references were found in French scientific journals on the possibilities of nuclear chain reaction and to element 94.

The following patent was uncovered in German scientific literature: Auergesellschaft, Berlin, "Separation of Difficultly-Separable Gas Mixtures by Diffusion." This patent is extremely interesting as it is the first evidence of German interest in the diffusion method and also bedause of its tie-up with Auergesellschaft.

MEMORANDUM TO: Major F. J. Smith
FROM: Karl Cohen

October 19, 1944

Evidence for an Enemy Diffusion Project

In the Kolloid Zeitschrift 106^3 201 (March 1944) an article by N. Riehl from the Scientific Center of the Auergesellschaft on "Some Observations on Diffusion of Gases through Rubber Films" begins as follows:

> "In the course of a series of investigations on the flow of gases through porous and other membranes with the object of separating gas mixtures by diffusion, (to be published shortly) the diffusion of gases through rubber was also investigated."

Porosity was measured by the rate of pressure loss through the membrane from a closed chamber. Extremely dry rubber was used, perhaps indicating application to gases reactive to water. Most of the observations were with air, but Radium emanation was also used - perhaps to see how high-molecular weight gases would act. The permeability coefficients were investigated as a function of molecular weights, and found to vary inversely as the square root of the masses (pure diffusion). The pressure-dependence of permeability was also investigated.

The time element of this investigation can be best judged by referring to the date April 17, 1941, the priority date of the Auer patent on a diffusion apparatus. Riehl's admission of a connection between diffusion through rubber and a gas separation project gives new meaning to an article by F. H. Müller "A simple apparatus for measuring the diffusion of gases through membranes", Physik Z. 42 48 (1941). His application are to high-polymer materials (triacetates, polystyrol, etc.), but the aim of the apparatus is to secure precise measurements over a wide range of porosities, for any gas - including condensible gases. Müller (Leipzig) is really interested in high polymers; if we assume he worked on a government project we are led to the interesting possibility that the enemy sought polymer screens for separating hex.

[The isotope sluice was an alternative form of gaseous diffusion invented by Erich Bagge. The principle was that in a beam of energetic uranium atoms/ions/molecules, lighter U-235 would travel slightly faster than heavier U-238. If that beam had to traverse a series of portals that quickly opened and closed with the right timing, the faster U-235 would be more likely to make it through than the slower U-238. The portals were generally holes in rapidly spinning disks. Because the isotope sluice involved energetic uranium beams and high-speed rotating machinery, it also had some characteristics of electromagnetic separators and centrifuges. Bagge led a team that successfully demonstrated isotope sluice prototypes during the war, and he tried unsuccessfully to attract enough support for the approach in the European nuclear industry after the war.

See pp. 3653–3662.]

Background investigation of Erich Bagge. 7 April 1952 [NARA RG 330, Entry A1-1B, Box 6, Folder Bagge, Erich]

On 28 March 1952, Frau Charlotte PRAGER nee BRINKMANN, a German national... now residing in BERLIN-Dahlem, Boltzmannstr. 19, was interviewed, and stated substantially as follows: BAGGE had lived in the neighborhood in 1941 with his wife and two (2) children. BAGGE worked in the Kaiser Wilhelm Institute for Physics; however, SOURCE was not sure what type of work BAGGE performed. In 1944, BAGGE and his family presumably departed for VIENNA (O49/X49), Austria. Since this time SOURCE has never seen or heard about BAGGE. [...]

[Did Bagge help transition his uranium-235 enrichment system to industrial-scale production someplace in Austria, such as at Gusen?]

Erich Bagge and Karl-Friedrich Leisinger. Patent DE1058024. Vorrichtung zur Trennung von Isotopen mit der Isotopenschleuse in der Gasphase. [Device for the Separation of Isotopes with the Isotope Sluice in the Gas Phase.] Filed 6 May 1955.

Es ist möglich, Isotope mit Hilfe der Isotopenschleuse nach einem von E. Bagge entwickelten Verfahren zu trennen. Die Methode besteht darin, daß man sich für das zu trennende Isotopengemisch einen Atom- oder Molekularstrahl herstellt, welcher ein System von intermittierenden Blenden durchsetzen muß. Die Blenden sind so eingerichtet, daß durch periodisches Öffnen und Schließen der Atom- oder Molekularstrahl in kleine Wölkchen zerhackt wird.

Die Wölkchen müssen dann über eine kurze Wegstrecke durch den Raum fliegen, wobei sich eine teilweise Trennung der Isotope vollzieht, indem sich die leichteren und dadurch schnelleren Teilchen an den Kopf des Wölkchens setzen, während die schwereren zurückbleiben. Das zweite Blendsystem sorgt dafür, daß die Wölkchen abermals zerteilt werden, indem die Spitze durchgelassen wird, während der Rest des Wölkchens zwischen den Blenden zurückbleibt. Auf diese Weise ist es möglich, aus dem ursprünglichen Atomstrahl einen neuen intermittierenden Strahl zu gewinnen, in dem die leichteren Isotope angereichert sind. Zur Ausbildung des primären Atomstrahls wird vor die erste intermittierende Blende eine raumfeste oder ein ganzes System räumlich feststehender Blenden gebracht. Das Verfahren, das sich in dieser Form auf Atomstrahlen leicht kondensierbarer Metalldämpfe mit Erfolg anwenden läßt, kann auch auf Gase übertragen werden.

It is possible to separate isotopes by means of the isotope sluice according to a method developed by E. Bagge. The method consists in producing an atomic or molecular beam for the isotope mixture to be separated, which must enforce a system of intermittent diaphragms. The apertures are arranged so that the atomic or molecular beam is chopped into small clouds by periodically opening and closing.

The small clouds then have to fly over a short distance through space, with a partial separation of the isotopes takes place by the lighter and thus faster particles sit on the head of the cloud, while the heavier remain behind. The second blend system causes the clouds to be split again by letting the tip through while leaving the rest of the cloud between the baffles. In this way, it is possible to obtain from the original atomic beam a new intermittent beam in which the lighter isotopes are enriched. To form the primary atom beam, a space-fixed or an entire system of spatially fixed diaphragms is brought before the first intermittent diaphragm. The method, which can be successfully applied in this form to atomic beams of easily condensable metal vapors, can also be applied to gases.

UNCLASSIFIED

Über die Möglichkeit einer ~~zur~~ Anreicherung der leichten Uranisotope mit der Isotopenschleuse.

Von E. Bagge.

In einer früheren Mitteilung[1] wurde ein Verfahren angegeben, mit dem es möglich sein muss, in einem Isotopengemisch die Gruppe der leichteren oder die der schwereren Partner anzureichern und dabei gleichzeitig zu technisch verwertbaren Mengen des gewünschten Stoffes zu gelangen. Es soll in dieser Arbeit die Leistungsfähigkeit der Methode im Hinblick auf eine Anreicherung der leichten Uranisotope kurz besprochen werden.

1.) Die Isotopenschleuse.

Die Anreicherungsmethode besteht darin, dass man einen Dampfstrahl des Isotopengemisches durch ein Blendensystem hindurchsendet, das von zwei rotierenden Scheiben gebildet wird. (sh. Abb. 1)

Abbildung 1

---

[1] E.Bagge: Ein rasch arbeitendes Verfahren zur Entmischung von Isotopen. (Bericht eingereicht im April 1941).

- 2 -

Umlaufszahl und Anordnung der Löcher auf den Scheiben müssen so eingerichtet sein, dass alle Atome, deren Geschwindigkeiten grösser sind als eine vorgegebene Geschwindigkeit V_o, durch das Blendensystem hindurchgelassen werden und den Auffänger erreichen können, während die Atome mit geringerer Geschwindigkeit zwischen den Scheiben aufgefangen werden. Dies führt infolge der verschiedenen Geschwindigkeitsverteilungen der isotopen Atomarten im Dampfstrahl unmittelbar zu einer Anreicherung der leichten Isotopen auf dem Auffänger.

Man erkennt dies leicht an den in Abb. 2 wiedergegebenen Verteilungsfunktionen für zwei Isotopenarten. Die Atome mit der kleineren Massenzahl haben im Dampfstrahl im Mittel eine etwas grössere Geschwindigkeit als die schwereren. Ihre Verteilungsfunktion ist darum in dieser Richtung verschoben. Schneidet man jetzt beide Verteilungsfunktionen oberhalb einer gewissen Geschwindigkeit ab (in der Abb. oberhalb $\frac{v_o}{v_m} = 2$), so erhält man eine Anreicherung der leichteren Isotope, wie sie in Abb. 2 der schraffierten Fläche entspricht.

Abbildung 2.

- 3 -

2.) Trenneffekt und ideale Ausbeute.

Der Betrag des Trenneffektes lässt sich unmittelbar berechnen. Die Geschwindigkeitsverteilung der Atome im Dampfstrom ist gegeben durch:

$$f(v)\,dv = 2\,\frac{v^3}{v_m^3}\,e^{-\frac{v^2}{v_m^2}}\,\frac{dv}{v_m} \tag{1}$$

Dabei ist V_m bestimmt durch die Bedingung:

$$\frac{m v_m^2}{2kT} = 1 \tag{2}$$

Massgebend für den Trenneffekt und die ideale Ausbeute ist jetzt das Integral:

$$\mathcal{A} = \int_{v_0}^{\infty} f(v)\,dv = \left(1+\frac{v_0^2}{v_m^2}\right)e^{-\frac{v_0^2}{v_m^2}} \tag{3}$$

Die Grenzen des Integrals sind dabei den Verhältnissen angepasst, wie sie durch die Wirkung des rotierenden Blendensystems auf den Dampfstrahl entstehen. Die Grösse $\mathcal{A}$ gibt im Falle des Urans, bei dem ja das Isotop ^{238}U in überwiegender Menge vorhanden ist, unmittelbar an, welcher Teil der Atome, die den Zwischenraum zwischen dem rotierenden Blenden erreichen, auch zum Auffänger gelangen. Sie stellt also die ideale Ausbeute dar. Die praktische Ausbeute hingegen, das Verhältnis der am Auffänger niedergeschlagenen Menge zur Menge des verdampften Urans, ist noch um einen Faktor kleiner, der durch die geometrischen Bedingungen der Strahlerzeugung bestimmt ist.

Der Trenneffekt τ für zwei verschiedene Isotopensorten folgt jetzt aus dem Verhältnis der entsprechenden Integrale (3) für die beiden Atomarten. Man bildet dazu zweckmässig den Ausdruck:

$$\tau = 1 - \frac{\mathcal{A}_1}{\mathcal{A}_2} = 1 - \frac{1+\frac{v_0^2}{v_{m1}^2}}{1+\frac{v_0^2}{v_{m2}^2}}\,e^{-v_0^2\left(\frac{1}{v_{m1}^2}-\frac{1}{v_{m2}^2}\right)} \tag{4}$$

- 4 -

Da bei Uran die Massen der verschiedenen Isotope nur um kleine Beträge im Verhältnis zu ihrer Gesamtmasse verschieden sind, kann man den Ausdruck (4) nach der Massendifferenz $\Delta m = m_2 - m_1$ unter Berücksichtigung von (2) entwickeln und erhält in ausreichender Näherung:

$$\tau = \frac{\Delta m}{m}\,\frac{\left(\frac{v_0}{v_m}\right)^4}{1+\left(\frac{v_0}{v_m}\right)^2} \tag{5}$$

$$\approx \frac{\Delta m}{m}\,\frac{v_0^2}{v_m^2} \quad \text{für} \quad v_0 \gg v_m \tag{5a}$$

Während also nach (3) die Ausbeute $\mathcal{A}$ mit wachsendem V_o exponentiell abnimmt, steigt der Trenneffekt τ nach (5a) quadratisch mit der Abschneidegeschwindigkeit an.

Die durch die Formeln (3) und (5) beschriebenen Verhältnisse sind für die beiden Atomsorten ^{235}U und ^{238}U in der Abb. 3 eingetragen. Trenneffekt und Ausbeute sind unmittelbar in Prozenten angegeben, und man sieht z.B., dass bei einer Anreicherung um 5 %, das heisst bei einem Anheben des Isotopenverhältnisses von 140:1 auf 133:1, eine Ausbeute von auch etwa 5 % er-

Abbildung 3.

- 5 -

zielt wird.

Wenn demnach 20 g des Atomstrahls die erste Blende durchsetzt haben, erreicht 1 g des um 5 % angereicherten Isotopengemisches den Auffänger.

Weitere Angaben erfolgen, sobald experimentelle Ergebnisse vorliegen.

Herrn Prof. Dr. Knauer danke ich für wertvolle Hinweise und Besprechungen.

Berlin, den 16. März 1942.

CAUTION RESTRICTED DATA

W.O. 22091

This document has been declassified by authority of issuing installation. Letter dated 6/4/50 Noted by

Die Anreicherung des leichten Silberisotops mit der Isotopenschleuse.

Von Erich Bagge.

In zwei früheren Arbeiten[1)] wurde gezeigt, dass es möglich sein muss, mit Hilfe der Isotopenschleuse eine partielle Entmischung der Uranisotope zu erzielen. Das Ausmass der Trennung hängt dabei in bestimmter, berechenbarer Weise von der mengenmässigen Ausbeute ab. Es liess sich abschätzen, dass mit einer solchen Anlage bei entsprechender technischer Ausgestaltung grössere Mengen eines angereicherten Isotopengemisches herstellbar sind.

Nach den bekannten ergebnislosen Versuchen, das leichte Uranisotop im Clusius-Dickelschen Trennrohr anzureichern, wurde darum im November 1941 auf eine Anregung von Prof. Harteck und auf Wunsch von Dr. Diebner hin mit dem Bau einer Isotopenschleuse begonnen. Die Absicht war dabei zunächst nur die, einmal auszuprobieren, ob die Methode an sich brauchbar ist und wirklich das leistet, was man sich theoretisch errechnet. Das Verfahren ist ja bisher in dieser Form noch nicht angewendet worden, und es war darum nötig, in einem Vorversuch zu zeigen, dass es gelingt, die Isotope zu entmischen. Es wurde darum auch von vornherein darauf verzichtet, eine Anlage aufzubauen, die sofort grössere Mengen des angereicherten Gemisches liefert. Vielmehr kam es bei diesem Versuch nur darauf an, eine solche Menge des gewünschten Stoffes herzustellen, dass ein einwandfreier Nachweis des Trenneffektes möglich war. Aus diesem Grunde wurde in der früher beschriebenen Anordnung die zu verdampfende Substanz nur durch einen einzigen Spalt hindurchgeschickt, während man im Prinzip bei unserer Anordnung 180 Spalte hätte anbringen können. Weiter wurde bei diesen Versuchen bisher noch

- 2 -

unterlassen, den maximal zulässigen Dampfdruck anzuwenden. Die Trennung wurde vielmehr sofort begonnen, als sich zeigte, dass die aus dem Spalt austretende Menge für unsere Zwecke ausreichte.

Auch wurde darauf verzichtet, den Trenneffekt direkt am Uranmetall nachzuweisen. Es erwies sich nämlich als ziemlich schwierig, dieses Metall in grösseren Mengen in reproduzierbarer Form zu verdampfen, und obwohl wir nunmehr in der Lage sind, dies zu tun, haben wir noch gezögert, es in der Trennapparatur selbst zu verdampfen, da der Metalldampf nach unseren Erfahrungen bei der hohen Betriebstemperatur möglicherweise mit Teilen der Apparatur chemisch reagiert. Mit Rücksicht darauf, dass aber bei einem technischen Einsatz dieser Methode ja ohnehin nicht mit Metalldampf, sondern sicher mit Uranhexafluorid gearbeitet werden wird, muss es als eine unnötige Mühe betrachtet werden, besonders viel Arbeit darauf zu verwenden, die Trennung nun gerade am Uranmetall durchzuführen, da eben hierbei Schwierigkeiten auftreten, die bei Verwendung des Hexafluorids von selbst fortfallen. Andererseits lagen zu der Zeit, als mit dem Bau der Anlage begonnen wurde, noch nicht genügende Erfahrungen vor, um mit dem Hexafluorid sicher arbeiten zu können. Dies ist zwar inzwischen auch der Fall, es wäre aber sehr schwierig gewesen, unsere im Bau befindliche Anlage auf den Betrieb mit Hexafluorid umzustellen, da dies neben der völligen Vernickelung auch noch besondere Massnahmen bei den Pumpen und beim Scheibenantrieb erfordert hätte.

Um möglichst bald zu einem greifbaren Ergebnis zu gelangen, wurde darum beschlossen, die Isotopenschleuse zunächst mit Silber zu betreiben.

Das Ergebnis ist folgendes: Aus einem einzigen Spalt von 1 mm Breite und etwa 10 mm effektiver Länge gelangten hinter den rotierenden Blenden unter bestimmten Bedingungen, die wir in einer ausführlichen Arbeit angeben werden, 0,33 mg/h der angereicherten Substanz auf den Auffänger. Die Bedingungen waren dabei so gewählt, dass nach den Abschätzungen, die allerdings für unendlich dünne untere Blende durchgeführt waren, eine Anreicherung des leichten Silberisotops um etwa 2 % hätte eintreten müssen. Diese Zahl müsste dabei als untere Grenze betrachtet werden, denn man konnte sofort sehen, dass für die wirkliche Blende die Verhältnisse nur günstiger liegen konnten.

- 3 -

In einer Arbeitszeit von 8 Stunden und vierzig Minuten wurden nun 3,066 mg des angereicherten Präparats auf eine Goldfolie aufgedampft und diese an Herrn Dr. Paul in Göttingen zur Untersuchung im Massenspektrometer weitergeleitet.

Nach Mitteilung des Herrn Dr. Paul zeigte nun eine genaue Untersuchung des Präparats, dass in der Tat eine Verschiebung des Mischungsverhältnisses der Isotope stattgefunden hat, und zwar beträgt diese mindestens 3 %, sicher aber nicht mehr als 5 %, d.h. also wenn man den Wert 3 % zugrunde legt, dass das leichte Isotop ^{107}Ag in seiner prozentualen Häufigkeit im Gemisch um 1,5 % zugenommen, das schwere Isotop ^{109}Ag um 1,5 % abgenommen hat, wenn man zum Vergleich das beim natürlich vorkommenden Silber vorliegende Häufigkeitsverhältnis heranzieht.

Die Anreicherung hat danach einen Wert, wie er zu dem theoretisch abgeschätzten durchaus passt. Genauere Rechnungen unter Berücksichtigung der endlichen Schlitzbreite und auch weitergehende Messungen müssen nun noch zeigen, bis zu welchem Grad von Genauigkeit sich beide in Übereinstimmung bringen lassen.

Herrn Dr. Paul, Göttingen, danke ich recht herzlich für die Durchführung der Messungen.

Der große Vorzug der Anordnung besteht darin, daß infolge ihrer Axialsymmetrie eine in sich geschlossene, ebenfalls axialsymmetrische Ionenfläche entsteht, in der sich die Raumladungskräfte in azimutaler Richtung überall kompensieren und in axialer Richtung klein sind wegen der geringen Höhe der „Ionenscheibe“ (letztere, um nicht zu große Polschuhabstände und damit Magnetleistungen zu erhalten). Voraussetzung dafür ist allerdings eine in azimutaler Richtung homogene Emission der Ionenquelle.

Außer der beschriebenen Anordnung hat EWALD auch eine solche mit Außenionenquelle und eine andere mit $r_b = r_c = \infty$ diskutiert. Er gelangt jedoch zu dem Schluß, daß für die Trennung schwerer Isotope die Apparatur mit Innenionenquelle am günstigsten ist. Im Anschluß an Ewald hat ARDENNE[117] einige für die praktische Ausführung des Isotopentrenners wichtige Daten (Abhängigkeit des praktischen Auflösungsvermögens von der relativen Häufigkeit der Isotope, Einfluß des Streufeldes, Ionenoptik, Massentransport, Ionisierungs-Wirkungsgrad, Energieaufwand) abgeschätzt, bzw. besprochen und einige konstruktive Vorschläge gemacht. Zu einer Ausführung von Versuchen ist es nicht mehr gekommen.

5. 7. 4 Die Isotopenschleuse

a) Prinzip der Anordnung: BAGGE[108] hat eine Methodik auf die Isotopentrennung übertragen, die in der Experimentalphysik schon mehrfach angewendet worden ist, so z. B. bei der Monochromasierung von Atom- und Neutronenstrahlen. Das Prinzip sei an Hand von Abb. 33 erläutert.

Abb. 33. Prinzip der Isotopenschleuse. B_0, B_1 ortsfeste Blenden, B_2, B_3 Blenden in zwei rotierenden Scheiben. A—A Rotationsachse. Breite der Blenden b senkrecht zur Zeichenebene: B_0, B_1, B_2 differentiell klein, B_3 endlich, jedoch $b \ll l$.

Aus der Blende B_0 des Ofens O, die, wie auch die Blenden B_1 und B_2, senkrecht zur Zeichenebene sehr schmal sein und in der Zeichenebene die Länge l besitzen soll, trete ein Dampf- oder Gas-Atomstrahl; er bildet hinter B_1 ein schmales Band. Die Blenden B_2 und B_3 seien in zwei um die Achse A-A rotierenden Scheiben angebracht. Bei der Rotation gibt die Blende B_2 für kurze Zeit den Atomstrahl frei und schließt wieder. Die Blende B_3 soll gleichzeitig mit B_2 den Strahl freigeben, wegen ihrer größeren Breite b jedoch erst später schließen. B_2 hackt auf diese Weise aus dem Atomstrahl ein Paket von Atomen heraus. Die schnelleren Atome dieses Paktes mit Geschwindigkeiten

$$v > v_0 = \frac{d \cdot \omega}{b} \cdot r_m$$

---

[117] M. V. ARDENNE, Sonderber. Mitt. Forsch.-Anst. dtsch. Reichspost.

(ω = Winkelgeschwindigkeit der Scheiben, andere Bezeichnungen vgl. Abb. 33) werden die zweite Scheibe noch passieren können; die langsameren hingegen werden im Raum zwischen den Scheiben abgefangen; es wird also das Ende der Geschwindigkeitsverteilung des Atomstrahls ab v_0 durchgelassen. Besteht der Atomstrahl aus zwei Sorten von Atomen mit verschiedener Masse, so werden von der leichteren Sorte relativ mehr Teilchen die Blende B_3 passieren als von der schwereren, und es wird eine Anreicherung des leichten Anteils hinter B_3, des schweren Anteils vor B_3 eintreten. Je nachdem, ob man es mit einem Gas- oder Dampfatomstrahl zu tun hat, können die beiden angereicherten Gemische abgepumpt oder kondensiert werden.

b) Berechnung des Trennfaktors: Unter Trennfaktor soll der Quotient q des Mischungsverhältnisses V_{II} des angereicherten Gemisches zu demjenigen des Ausgangsgemisches V_{I} verstanden werden. Bei kleinen Trennfaktoren gibt man bequemer den „Trenneffekt“

$$\tau = q - 1 = \frac{V_{\mathrm{II}} - V_{\mathrm{I}}}{V_{\mathrm{I}}}$$

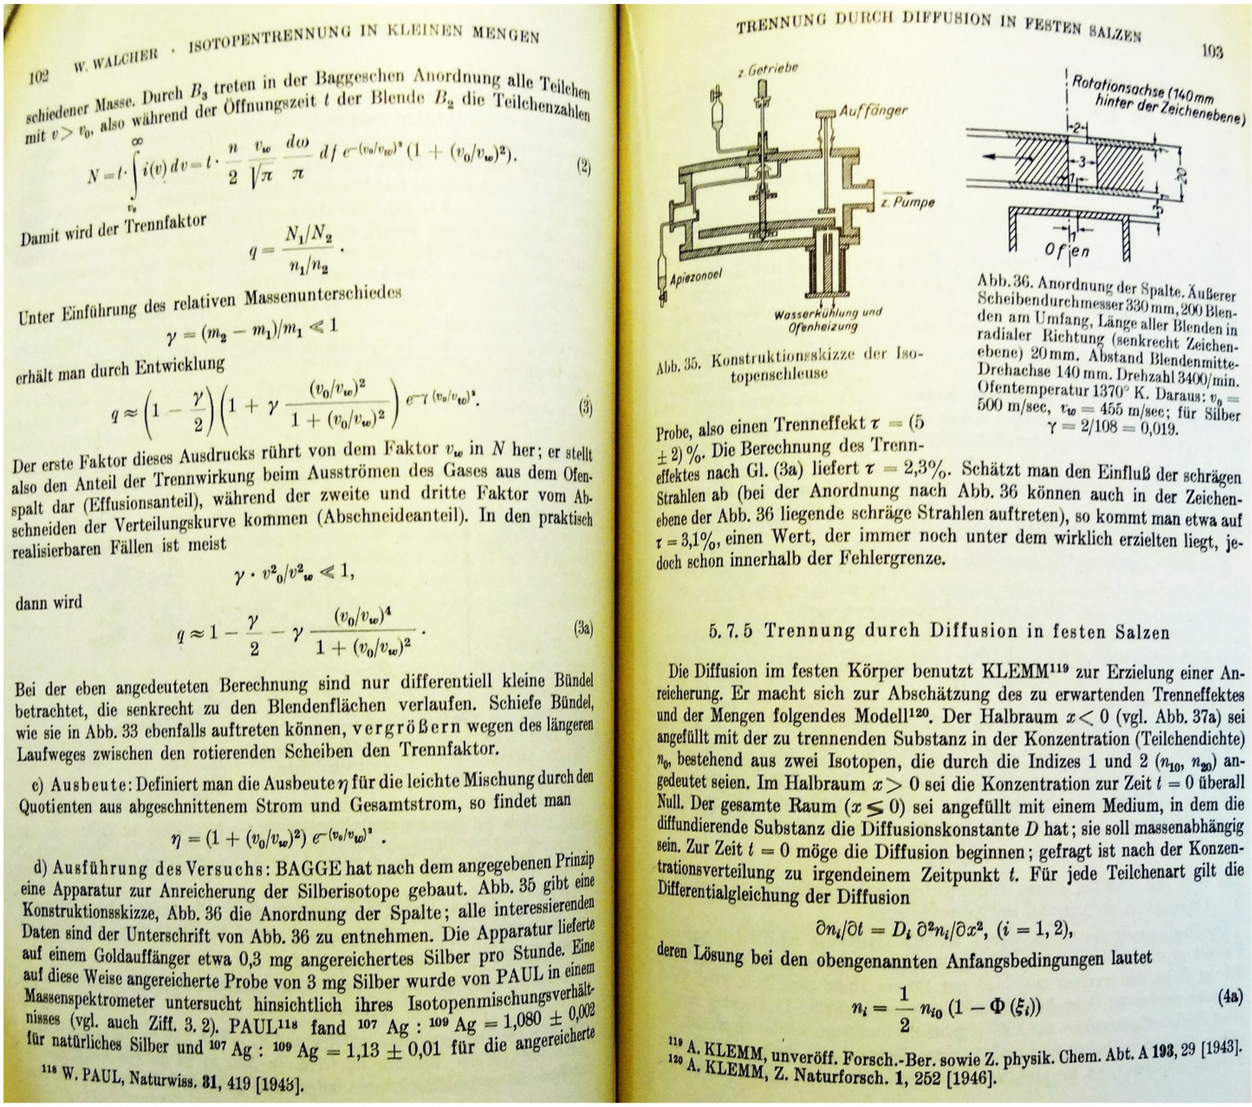
an. Man findet für die oben beschriebene Anordnung q bzw. τ für die „leichte Seite“ aus dem Anteil des Teilchenstromes mit Geschwindigkeiten zwischen v und $v + dv$, der aus dem Flächenelement df des Ofenspaltes senkrecht in das Raumwinkelelement $d\omega$ eintritt. Dieser Anteil ist gemäß dem Maxwellschen Verteilungsgesetz

Abb. 34. Geschwindigkeitsverteilung im Atomstrahl. v_w wahrscheinliche Geschwindigkeit im Ofen. Schraffierte Flächen: Durch das rotierende Blendensystem durchgelassene Teilchenströme.

$$i(v)\,dv = n\,\frac{v_w}{\sqrt{\pi}}\,\frac{d\omega}{\pi}\,df\,(v/v_w)^3\,e^{-(v/v_w)^2}\,d(v/v_w)\,. \tag{1}$$

Dabei ist n die Teilchendichte im Ofen und $v_w = \sqrt{2kT/m}$ die wahrscheinlichste Geschwindigkeit der Teilchen im Ofen. In Abb. 34 ist die Geschwindigkeitsverteilung dieses Teilchenstromes aufgetragen für zwei Teilchensorten mit ver-

Figure D.251: During the war, Erich Bagge led a team that invented, built, and demonstrated the “isotope sluice,” an alternative form of gaseous diffusion enrichment [FIAT Rev: *Nuclear Physics and Cosmic Rays* Vol. II, pp. 100–103].



schiedener Masse. Durch B_3 treten in der Baggeschen Anordnung alle Teilchen mit $v > v_0$, also während der Öffnungszeit t der Blende B_2 die Teilchenzahlen

$$N = t \cdot \int_{v_0}^{\infty} i(v)\, dv = t \cdot \frac{n}{2}\, \frac{v_w}{\sqrt{\pi}}\, \frac{d\omega}{\pi}\, df\, e^{-(v_0/v_w)^2} \left(1 + (v_0/v_w)^2\right). \qquad (2)$$

Damit wird der Trennfaktor

$$q = \frac{N_1/N_2}{n_1/n_2}\,.$$

Unter Einführung des relativen Massenunterschiedes

$$\gamma = (m_2 - m_1)/m_1 \ll 1$$

erhält man durch Entwicklung

$$q \approx \left(1 - \frac{\gamma}{2}\right)\left(1 + \gamma\, \frac{(v_0/v_w)^2}{1 + (v_0/v_w)^2}\right) e^{-\gamma\,(v_0/v_w)^2}. \qquad (3)$$

Der erste Faktor dieses Ausdrucks rührt von dem Faktor v_w in N her; er stellt also den Anteil der Trennwirkung beim Ausströmen des Gases aus dem Ofenspalt dar (Effusionsanteil), während der zweite und dritte Faktor vom Abschneiden der Verteilungskurve kommen (Abschneideanteil). In den praktisch realisierbaren Fällen ist meist

$$\gamma \cdot v^2{}_0/v^2{}_w \ll 1,$$

dann wird

$$q \approx 1 - \frac{\gamma}{2} - \gamma\, \frac{(v_0/v_w)^4}{1 + (v_0/v_w)^2}\,. \qquad (3a)$$

Bei der eben angedeuteten Berechnung sind nur differentiell kleine Bündel betrachtet, die senkrecht zu den Blendenflächen verlaufen. Schiefe Bündel, wie sie in Abb. 33 ebenfalls auftreten können, vergrößern wegen des längeren Laufweges zwischen den rotierenden Scheiben den Trennfaktor.

c) Ausbeute: Definiert man die Ausbeute η für die leichte Mischung durch den Quotienten aus abgeschnittenem Strom und Gesamtstrom, so findet man

$$\eta = (1 + (v_0/v_w)^2)\, e^{-(v_0/v_w)^2}\,.$$

d) Ausführung des Versuchs: BAGGE hat nach dem angegebenen Prinzip eine Apparatur zur Anreicherung der Silberisotope gebaut. Abb. 35 gibt eine Konstruktionsskizze, Abb. 36 die Anordnung der Spalte; alle interessierenden Daten sind der Unterschrift von Abb. 36 zu entnehmen. Die Apparatur lieferte auf einem Goldauffänger etwa 0,3 mg angereichertes Silber pro Stunde. Eine auf diese Weise angereicherte Probe von 3 mg Silber wurde von PAUL in einem Massenspektrometer untersucht hinsichtlich ihres Isotopenmischungsverhältnisses (vgl. auch Ziff. 3. 2). PAUL[118] fand ^{107}Ag : ^{109}Ag = 1,080 ± 0,002 für natürliches Silber und ^{107}Ag : ^{109}Ag = 1,13 ± 0,01 für die angereicherte Probe, also einen Trenneffekt τ = (5 ± 2) %. Die Berechnung des Trenneffektes nach Gl. (3a) liefert τ = 2,3%. Schätzt man den Einfluß der schrägen Strahlen ab (bei der Anordnung nach Abb. 36 können auch in der Zeichenebene der Abb. 36 liegende schräge Strahlen auftreten), so kommt man etwa auf τ = 3,1%, einen Wert, der immer noch unter dem wirklich erzielten liegt, jedoch schon innerhalb der Fehlergrenze.

Abb. 35. Konstruktionsskizze der Isotopenschleuse

Abb. 36. Anordnung der Spalte. Äußerer Scheibendurchmesser 330 mm, 200 Blenden am Umfang, Länge aller Blenden in radialer Richtung (senkrecht Zeichenebene) 20 mm. Abstand Blendenmitte-Drehachse 140 mm. Drehzahl 3400/min. Ofentemperatur 1370° K. Daraus: v_0 = 500 m/sec, v_w = 455 m/sec; für Silber $\gamma = 2/108 = 0{,}019$.

5.7.5 Trennung durch Diffusion in festen Salzen

Die Diffusion im festen Körper benutzt KLEMM[119] zur Erzielung einer Anreicherung. Er macht sich zur Abschätzung des zu erwartenden Trenneffektes und der Mengen folgendes Modell[120]. Der Halbraum $x < 0$ (vgl. Abb. 37a) sei angefüllt mit der zu trennenden Substanz in der Konzentration (Teilchendichte) n_0, bestehend aus zwei Isotopen, die durch die Indizes 1 und 2 (n_{10}, n_{20}) angedeutet seien. Im Halbraum $x > 0$ sei die Konzentration zur Zeit $t = 0$ überall Null. Der gesamte Raum ($x \lesssim 0$) sei angefüllt mit einem Medium, in dem die diffundierende Substanz die Diffusionskonstante D hat; sie soll massenabhängig sein. Zur Zeit $t = 0$ möge die Diffusion beginnen; gefragt ist nach der Konzentrationsverteilung zu irgendeinem Zeitpunkt t. Für jede Teilchenart gilt die Differentialgleichung der Diffusion

$$\partial n_i/\partial t = D_i\, \partial^2 n_i/\partial x^2, \ (i = 1, 2),$$

deren Lösung bei den obengenannten Anfangsbedingungen lautet

$$n_i = \frac{1}{2}\, n_{i0}\, (1 - \Phi(\xi_i)) \qquad (4a)$$

Vorrichtung zur Trennung von Isotopen mit der Isotopenschleuse in der Gasphase

Anmelder:

Dr. Kurt Diebner,
Kiel, Hindenburgufer 63

Dr. Erich Bagge, Hamburg-Wandsbek,
und Dr. Karl-Friedrich Leisinger, Frankfurt/M.,
sind als Erfinder genannt worden

Es ist möglich, Isotope mit Hilfe der Isotopenschleuse nach einem von E. Bagge entwickelten Verfahren zu trennen. Die Methode besteht darin, daß man sich für das zu trennende Isotopengemisch einen Atom- oder Molekularstrahl herstelltt, welcher ein System von intermittierenden Blenden durchsetzen muß. Die Blenden sind so eingerichtet, daß durch periodisches Öffnen und Schließen der Atom- oder Molekularstrahl in kleine Wölkchen zerhackt wird. Die Wölkchen müssen dann über eine kurze Wegstrecke durch den Raum fliegen, wobei sich eine teilweise Trennung der Isotope vollzieht, indem sich die leichteren und dadurch schnelleren Teilchen an den Kopf des Wölkchens setzen, während die schwereren zurückbleiben. Das zweite Blendsystem sorgt dafür, daß die Wölkchen abermals zerteilt werden, indem die Spitze durchgelassen wird, während der Rest des Wölkchens zwischen den Blenden zurückbleibt. Auf diese Weise ist es möglich, aus dem ursprünglichen Atomstrahl einen neuen intermittierenden Strahl zu gewinnen, in dem die leichteren Isotope angereichert sind. Zur Ausbildung des primären Atomstrahls wird vor die erste intermittierende Blende eine raumfeste oder ein ganzes System räumlich feststehender Blenden gebracht. Das Verfahren, das sich in dieser Form auf Atomstrahlen leicht kondensierbarer Metalldämpfe mit Erfolg anwenden läßt, kann auch auf Gase übertragen werden. Dabei tritt allerdings die Schwierigkeit auf, daß normale Gasmoleküle an dem intermittierenden Blendensystem nicht niedergeschlagen, sondern von ihm reflektiert werden. So kommt es zustande, daß die ursprünglich einem Atomstrahl angehörenden Gasmoleküle sich im Raum zwischen den intermittierenden Blenden längere Zeit aufhalten und damit zu Störeffekten Anlaß geben, die den Trennprozeß verändern.

Es können jedoch auch solche Gase, die bei der Temperatur der flüssigen Luft oder der festen Kohlensäure kondensierbar sind und die unter diesen Bedingungen nach der Kondensation einen so niedrigen Dampfdruck besitzen, daß dieser den Trennvorgang der Isotope nicht stört, in einer derartigen Vorrichtung wirksam getrennt werden, wenn man im Zwischenraum zwischen die beiden intermittierenden Blendensysteme, den der Molekularstrahl durchsetzen muß, bei Temperaturen der festen Kohlensäure oder der flüssigen Luft betriebene Kühlfallen in solcher Weise anbringt, daß diese für das zu trennende Isotopengemisch wie sehr rasch arbeitende Pumpen wirken. In diesem Raum wird dann das durch die Reflexionen der Gasmoleküle sich ansammelnde Gas sehr rasch weggepumpt.

Die technische Realisierung der oben angedeuteten Methode kann verschieden erfolgen. In der ursprünglichen Form der Isotopenschleuse wurde der Atomstrahl durch zwei rotierende Blenden hindurchgesandt, die auf einer Scheibe angebracht waren. Die Scheiben hatten dabei zahnradartige Ausschnitte verschiedener Größe, die in ihrer Phasenlage gegeneinander versetzt waren. Eine andere Möglichkeit besteht darin, daß man den Atomstrahl durch ein von zwei koaxial und starr verbundenen rotierenden Zylindern hindurchtreten läßt, die in Richtung ihrer Mantellinien Schlitze als Blenden tragen. Der Atomstrahl muß dann entweder vom inneren Zylinder aus durch das System der beiden rotierenden Zylinder nach außen hindurchgehen oder umgekehrt sich von außen nach innen bewegen. Es ist aber auch denkbar, die intermittierenden Blenden auf ganz andere Weise arbeiten zu lassen, indem man z. B. zwei solche Systeme von Blenden auf elektromagnetische Weise öffnet und schließt. Beim Betrieb der Isotopenschleuse muß der Druck des einzuschießenden Gases von solcher Größe sein, daß Atomstrahlen entstehen können. Dies ist der Fall, wenn die freie Weglänge der Gasmoleküle für die Stöße gegeneinander von der Größenordnung der Blendendimensionen ist.

Beim Betrieb der Isotopenschleuse ist im Auffangraum hinter der zweiten intermittierenden Blende für gutes Vakuum, d. h. für schnelles Abpumpen der diese Blende durchsetzenden Moleküle, zu sorgen, damit nicht etwa eine Rückdiffusion in den Raum zwischen den intermittierenden Blenden erfolgt. Weiter muß durch Labyrinthdichtungen der Raum zwischen den Blenden und dem Vorrats- bzw. dem Auffangraum für den Gasstrom genügend gegeneinander abgedichtet ein, damit nicht etwa auf Umwegen das Gas vom Innenraum unter Vermeiden des eigentlichen Trennraumes in den Auffangraum gelangen kann. Die Isotopenschleuse wird dazu beispielsweise in einem vakuumdichten Gefäß untergebracht und der Antrieb der rotierenden Zylinder in solcher Weise vorgenommen, daß das Vakuum aufrechterhalten bleibt.

Ein Ausführungsbeispiel der mit Atomen oder Molekülen gasförmiger Substanzen betriebenen Isotopenschleuse zur Anreicherung der schweren Isotope zeigen die Abb. 1 und 2.

Durch die Zuführung **1** wird das Gas in den Gasvorratsraum **2** eingeleitet. Das intermittierende Blendensystem **3** besteht aus einem inneren Blendensystem **3***a* und einem äußeren System **3***b*. Betrieben wird das Blendensystem durch den magnetischen Antrieb **3***c* und den magnetischen Mitnehmer **3***e*, die durch eine dünne Scheibe aus isolierendem und unmagnetischem Material **3***d* getrennt sind. Das ganze System bewegt sich in einem Lager **4***a*, und die Achse befindet sich in einer Führung **4***b*. Der eigentliche Trennraum **5** befindet sich zwischen den beiden intermittierenden Blendensystemen und ist vom Gasvorratsraum **2** sowie vom Auffangraum **8** durch die Labyrinthdichtungen **6** getrennt. Außerdem sind zwischen den rotierenden Blenden **3***a* und **3***b* Kühlfallen **7** angebracht. Eine weitere Kühlfalle **9** steht in direkter Verbindung mit dem Auffangraum **8**. Diese Kühlfalle **9** wird von einem doppelwandigen Gefäß **10** umgeben, das mit flüssiger Luft gefüllt ist und für die Kondensation des Gases im Auffangraum **8** sorgt. Unmittelbar an die Kühlfalle **9** schließt sich die Zuleitung zur Hochvakuumpumpe **12** an. Der Schnitt (Abb. 2) senkrecht zur Achse zeigt noch einmal die rotierenden Blenden **3***a* und **3***b*, und der eingezeichnete Pfeil **11** kennzeichnet die Richtung des zu trennenden Gasstromes.

PATENTANSPRÜCHE:

1. Vorrichtung zur Trennung von Isotopen in der Gasphase unter Verwendung gasförmiger Verbindungen der zu trennenden Isotope, die bei der Temperatur der flüssigen Luft oder der festen Kohlensäure kondensierbar sind, mit der Isotopenschleuse, dadurch gekennzeichnet, daß im Zwischenraum zwischen den rotierenden Blenden (**3**) Kühlfallen (**7**) und bzw. oder Pumpleitungen angeordnet sind.

2. Vorrichtung nach Anspruch 1, dadurch gekennzeichnet, daß als rotierende Blenden zwei koaxiale, miteinander verbundene und Schlitze enthaltende Zylinder angeordnet sind.

3. Abänderung der Vorrichtung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß an Stelle der rotierenden Blenden die Blenden räumlich fest angeordnet sind und auf elektrische oder magnetische Weise geöffnet und geschlossen werden.

4. Vorrichtung nach Anspruch 1 und 2, dadurch gekennzeichnet, daß der Trennraum zwischen den rotierenden Scheiben durch Labyrinthdichtungen an einer oder an beiden Blenden gegen den Vorrats- und Auffangraum abgedichtet ist.

5. Vorrichtung nach Anspruch 2 und 4, dadurch gekennzeichnet, daß die rotierenden Blenden von außen, d. h. von der freien Atmosphäre, über eine Scheibe oder ein Rohr auf magnetische oder magnetelektrische Weise· oder mit einer Welle angetrieben ist, wobei die Welle durch auf der Welle aufsitzende Dichtungsringe bzw. durch eine Öldurchflußdichtung abgedichtet ist.

S. A. Goudsmit
Brookhaven National Laboratory
Upton, L. I., New York 11973

Dear Sam:

I was pleased to receive your letter of 15 June 1966, and to hear of the "isotope sluice" process for separating uranium isotopes. The Production Division tells me that we know it as the "Bagge" process, but that little has been done in the way of detailed development.

I have asked that the appropriate AEC groups be appraised of the current German interest in the process.

Sincerely yours,

Howard

Mr. Howard C. Brown
Assistant General Manager
U.S. Atomic Energy Commission
Germantown, Maryland

Dear Howard:

I don't know whether this information is new to those who should have it but I thought I would let you know anyway.

The Germans are reviving an isotope separation method which they worked on during the war. It is the so-called "isotope sluice", devised by E. Bagge. Bagge believes that his method already was promising twenty years ago and that with modern techniques it might be superior to centrifuges, especially for the separation of uranium. At present it is still a small investigation, but ~~bares~~ bears watching.

Best regards.

Figure D.255: Samuel Goudsmit to Howard C. Brown. 15 June 1966 [NARA RG GOUDS, Entry UD-7420, Box 8, Folder Haycock/Brown/Tape AEC]. "The Germans are reviving an isotope separation method which they worked on during the war. It is the so-called 'isotope sluice', devised by E. Bagge. Bagge believes that his method already was promising twenty years ago and that with modern techniques it might be superior to centrifuges, especially for the separation of uranium."

D.4.5 Uranium-235 Enrichment via Photochemical Processes

[Beginning in the early 1930s, Stanisław Mrozowski (Polish, 1902–1999), K. Zuber (Swiss, 19??–19??), Werner Kuhn (Swiss, 1899–1963), Hans Martin (German, 19??–19??), and K. H. Eldau (German, 19??–19??) developed photochemical methods of isotope separation and demonstrated them with isotopes of elements such as mercury and chlorine. During the war, Kuhn, Martin, Eldau, Paul Harteck, and others seriously investigated the feasibility of applying such photochemical methods to uranium isotope separation. Publicly available documentation does not indicate how far that research progressed during the war, but given the available light sources, the photochemical enrichment of uranium seems unlikely to have ever gone beyond small-scale laboratory experiments.

Separately from the work on photochemical enrichment, or perhaps even motivated by it, other German-speaking scientists during the same time period worked toward the development of lasers as an improved monochromatic light source (Section C.3). After the war, the combination of the German-derived innovations in photochemical enrichment and laser technology made laser isotope enrichment a reality (p. 5127).]

Stanisław Mrozowski. 1930. *Bulletin of the Academy of Poland* 1:464.

Stanisław Mrozowski. 1932. Stoßerscheinungen bei optischer Anregung verschiedener Quecksilberisotopen. *Zeitschrift für Physik* 78:826–843.
https://doi.org/10.1007/BF01342044

Die Konstruktion einer neuen, sehr lichtstarken Anordnung hat es ermöglicht, die Hyperfeinstruktur der mit gefilterter Strahlung angeregten Resonanzstrahlung des Quecksilberdampfes unter verschiedenen Bedingungen zu erforschen und den früher entdeckten Verschiebungseffekt einer der Komponenten mit einer wesentlich höheren Genauigkeit festzustellen. Der Einfluß der nichtauslöschenden Zusatzgase äußert sich durch selektive Stoßüberführungen zwischen verschiedenen Hyperfeinstrukturkomponenten; dagegen wird bei Vergrößerung der Dampfdichte des Quecksilbers gleiche Überführungswahrscheinlichkeit für alle Komponenten beobachtet. Es wurde auch unter denselben Bedingungen ein Füchtbauereffekt erhalten, der bei Zusatz von Stickstoff die Hyperfeinstruktur des sichtbaren Tripletts zu studieren erlaubte. Es zeigt sich, daß die Hyperfeinstruktur von der Zusammensetzung der anregenden Resonanzlinie unabhängig ist, was in dem Einfluß der Stöße der metastabilen Atome mit Quecksilberatomen verschiedener Isotopenarten eine Erklärung findet.

The construction of a new, very high-intensity device has made it possible to explore the hyperfine structure of the resonance radiation of mercury vapor excited with filtered radiation under various conditions and to detect the previously discovered shift effect of one of the components with a much higher accuracy. The influence of the non-quenching additional gases is manifested by selective impact transfers between different hyperfine structure components; on the other hand, when the vapor density of mercury is increased, equal transfer probability is observed for all components. A fugacity effect was also obtained under the same conditions, which allowed to study the hyperfine structure of the visible triplet when nitrogen was added. It is shown that the hyperfine structure is independent of the composition of the exciting resonance line, which finds an explanation in the influence of the collisions of the metastable atoms with mercury atoms of different isotopic species.

K. Zuber. 1935. Die Linienabsorption des Quecksilberdampfes für einzelne Hyperfeinstruktur-Komponenten der Linie 2537 Å.E. *Helvetica Physica Acta* 8:4:370–380. https://dx.doi.org/10.5169/seals-110535

Messungen der Linienabsorption einzelner Hyperfeinstruktur-Komponenten führen zu Ergebnissen, welche mit dem Feinstrukturschema von Schüler und Keyston unter Berücksichtigung der von Inglis angegebenen Korrektur in Einklang stehen, falls man die mittlere Lebensdauer des 2 $^3P_1$-Niveaus im Gegensatz zu Mrozowski für alle Isotope gleich gross annimmt. Aus der Absorption für einzelne Komponenten lässt sich der Absorptionskoeffizient $k_{\lambda o}$ der ganzen Linie berechnen. Dieser Wert steht in guter Übereinstimmung mit den Messungen von Kunze und Ladenburg-Wolfsohn.

Measurements of the line absorption of individual hyperfine structure components lead to results which are in agreement with the fine structure scheme of Schüler and Keyston, taking into account the correction given by Inglis, if one assumes the mean lifetime of the 2 $^3P_1$ level to be the same for all isotopes, in contrast to Mrozowski. From the absorption for individual components, the absorption coefficient $k_{\lambda o}$ of the whole line can be calculated. This value is in good agreement with the measurements of Kunze and Ladenburg-Wolfsohn.

K. Zuber. 1935. Separation of the Mercury Isotopes by a Photochemical Method. *Nature* 136:796. https://doi.org/10.1038/136796a0

When a mixture of mercury vapour and oxygen is irradiated with the mercury resonance line λ 2537, the mercury becomes oxidised. Since excitation is a necessary stage in the oxidation, Mrozowski has suggested that it should be possible to produce a separation of the mercury isotopes by exciting them selectively. If the reaction consists of the primary photochemical process

$$\mathrm{Hg}^{+} + \mathrm{O}_2 \rightarrow \mathrm{HgO} + \mathrm{O}$$

only the atomic species which are excited by the incident light should be oxidised.

In my experiments the light from a mercury arc was passed through a Mrozowski filter consisting of a column of mercury vapour in a magnetic field. This transmitted only the hyperfine structure components of the resonance line corresponding to the isotopes 200, 202. After an irradiation of between 10 and 30 minutes, the isotopic composition of the remaining mercury or of that recovered from the oxide was examined by the method of absorption of single hyperfine structure components. The results of the experiments show:

(1) The separation is in every case only partial, so that besides the primary process, secondary reactions must take place.

(2) An addition of nitrogen assists the separation ($p_{\mathrm{O2}} : p_{\mathrm{N2}} \sim 1:1$, $p_{\mathrm{O2}} \sim 1$ mm. Hg).

(3) It has been possible to obtain samples in which the ratio $\frac{p_{200,\,202}}{p_{198,\,199,\,201,\,204}}$ was modified by a factor of four.

More detailed information will be published in the *Helv. Phys. Acta.*

K. Zuber. 1936. Trennung der Quecksilber-Isotope nach einer photochemischen Methode. *Helvetica Physica Acta* 9:285–300. https://dx.doi.org/10.5169/seals-110628

Bestrahlt man ein Gemisch von Hg-Dampf und Sauerstoff mit der Resonanzlinie 2537 Å. E., so tritt Oxydation des Quecksilbers ein. Da sich das Oxyd nur nach vorheriger Anregung der Quecksilberatome bildet, schlägt Mrozowski vor, einzelne Isotopensorten anzuregen. Besteht die Reaktion allein aus dem photochemischen Primärprozess $Hg^* + O_2 = HgO + O$, so sollten sich im Oxyd nur die vorher angeregten Isotopen wiederfinden. Es ergibt sich: 1. Das Gemisch Hg und O_2 ist für eine Trennung nicht geeignet. Notwendig ist ein Zusatz von Stickstoff. 2. Die Trennung ist immer nur teilweise, wofür sekundäre Reaktionen als Ursache angesehen werden. 3. Durch Wiederholen des Versuches lässt sich die Trennung verbessern. Es konnten Proben hergestellt werden, bei denen das Verhältnis der einzelnen Isotope um den Faktor vier verschieden war.

If a mixture of Hg vapor and oxygen is irradiated with the resonance line 2537 Å. E., oxidation of the mercury occurs. Since the oxide forms only after prior excitation of the mercury atoms, Mrozowski proposes to excite individual isotope species. If the reaction consists solely of the primary photochemical process $Hg^+ + O_2 = HgO + O$, only the previously excited isotopes should be found in the oxide. It results: 1. The mixture Hg and O_2 is not suitable for separation. An addition of nitrogen is necessary. 2. separation is always partial, for which secondary reactions are considered to be the cause. 3. separation can be improved by repeating the experiment. Samples could be produced in which the ratio of the individual isotopes was different by a factor of four.

Werner Kuhn and Hans Martin. 1932. Photochemische Trennung von Isotopen. *Naturwissenschaften* 20:772. https://doi.org/10.1007/BF01494810

Werner Kuhn and Hans Martin. 1933. Photochemische Trennung von Isotopen. *Zeitschrift für Physikalische Chemie B* 21:93. https://doi.org/10.1515/zpch-1933-2111

Es werden die Grundlagen und Voraussetzungen einer photochemischen Tren-nung von Isotopen in optischer, photochemischer und chemischer Hinsicht auseinandergesetzt und insbesondere im Falle des Phosgens genau diskutiert. Im Anschluss daran wird eine Versuchsanordnung beschrieben, mit welcher äusserst monochromatisches Licht in guter Ausbeute erhalten wird und für die präparative Darstellung benutzt werden kann. Chlor, welches in dieser Weise aus Phosgen freigemacht wurde, zeigte gegenüber gewöhnlichem Chlor eine Atomgewichtsverschiebung von 0.025 Einheiten. Es wird dadurch die Interpretation von Bandenvervielfachungen im Phosgenabsorptionsspektrum als Isotopieeffekt bestätigt, und es können weitere Schlüsse gezogen werden, namentlich mit Bezug auf die Zerfallswahrscheinlichkeiten in den den Prädissoziationsgebieten benachbarten Bereichen diskontinuierlicher Absorption.

The fundamentals and prerequisites of photochemical separation of isotopes in optical, photochemical, and chemical terms are discussed in detail, particularly in the case of phosgene. Subsequently, an experimental setup is described with which extremely monochromatic light is obtained in good yield and can be used for preparative imaging. Chlorine liberated from phosgene in this manner showed an atomic weight shift of 0.025 units compared to ordinary chlorine. This confirms the interpretation of band multiplications in the phosgene absorption spectrum as an isotopic effect, and further conclusions can be drawn, namely with respect to the decay probabilities in the regions of discontinuous absorption adjacent to the predissociation regions.

Werner Kuhn, Hans Martin, and K. H. Eldau. 1941. Anreicherung der Chlorisotopen durch Bestrahlung von Chlordioxyd bei niedrigem Druck. ***Zeitschrift für Physikalische Chemie B*** **50:213–254. https://doi.org/10.1515/zpch-1941-5014**

Anschließend an eine Diskussion der Stoffeigenschaften, welche die photochemische Trennung von Isotopen einerseits ermöglichen, andererseits herabmindern, wird gesagt, daß Chlordioxyd (ClO_2) eine Substanz sein dürfte, mit der bei Benutzung einer geeigneten Lichtquelle gute Ergebnisse erwartet werden können. Es wird darauf eine Apparatur beschrieben, mittels deren sehr reines Chlordioxyd dargestellt und unter einem Drucke von etwa 0.2 mm Hg mit praktisch reinem Lichte der Quecksilberlinien 3650.15, 3654.83 und 3663.27 Å bei Vermeidung von Reaktionsketten bestrahlt werden kann und welche gestattet, das dabei freigesetzte Chlor von unverändertem Chlordioxyd zu trennen. In den mit der Apparatur ausgeführten Versuchen wird einerseits festgestellt, daß die Quantenausbeute unter den gewählten Versuchsbedingungen tatsächlich ungefähr gleich 1 ist und daß als Zersetzungsprodukte praktisch ausschließlich Chlor und Sauerstoff gebildet werden. Andererseits wird in dem photochemisch freigesetzten Chlor eine Vermindeiung des Atomgewichts um 0.016 Einheiten gegenüber gewöhnlichem Chlor festgestellt. Das geringe Ausmaß der erzielten Trennung wird darauf zurückgeführt, daß von den drei genannten Quecksilberlinien nur die dritte mit einer Absorptionsbande von ClO_2 genau zusammenfällt und daß die anderen Linien, welche sich weniger eignen, im Gegensatz zu vorhandenen Literaturangaben eine Intensität besitzen, welche die der "geeigneten" Linie zusammen etwa um einen Faktor 4 übertrifft.

Following a discussion of the properties of the substance which on the one hand make possible the photochemical separation of isotopes and on the other hand reduce it, it is said that chlorine dioxide (ClO_2) is a substance with which good results can be expected when a suitable light source is used. An apparatus is described by means of which very pure chlorine dioxide can be prepared and irradiated under a pressure of about 0.2 mm Hg with practically pure light of the mercury lines 3650.15, 3654.83, and 3663.27 Å, while avoiding reaction chains, and which permits the chlorine thus released to be separated from unchanged chlorine dioxide. In the experiments carried out with the apparatus, it is found, on the one hand, that the quantum yield under the selected experimental conditions is indeed approximately equal to 1 and that practically only chlorine and oxygen are formed as decomposition products. On the other hand, a reduction in atomic weight of 0.016 units is found in the photochemically liberated chlorine as compared with ordinary chlorine. The small extent of the separation obtained is attributed to the fact that, of the three mercury lines mentioned, only the third coincides exactly with an absorption band of ClO_2 and that the other lines, which are less suitable, have, contrary to existing literature data, an intensity which exceeds that of the "suitable" line together by a factor of about 4.

G-156. Paul Harteck. The Separation of Isotopes with Special Reference to the Isotopes of Uranium. Die Trennung von Isotopen unter besonderer Berücksichtigung der Isotopen des Urans. 1942. pp. 10–11, 18.

10.) Das von einem Molekül angewendete Bandenspektrum (bezw. sein Absorbtionsspektrum) ist von der isotopischen Zusammensetzung abhängig, da jede Linie im Bandenspektrum durch eine quantenhafte Energieänderung seiner Elektronenenergie, der Schwingungs- und der Rotationsenergie des Moleküls entsteht. Setzt man die reduzierte Masse des Moleküls $\frac{m_1 m_2}{m_1+m_2}$ (wo m_1 und m_2 die Massen der Molekülpartner bedeuten) gleich μ, so ist bei einer Massenänderung von m_1, in m_1', d.h. von μ in μ' die Aenderung der Elektronenenergie in fast allen Fällen zu vernachlässigen; die Aenderung der Schwingungsenergie dagegen bedingt in erster Näherung eine Frequenzverschiebung um den Betrag

10.) The band spectrum applied by a molecule (i.e. its absorption spectrum) depends on the isotopic composition, since each line in the band spectrum is formed by a quantum energy change of its electron energy, the vibrational energy and the rotational energy of the molecule. If one sets the reduced mass of the molecule $\frac{m_1 m_2}{m_1+m_2}$ (where m_1 and m_2 mean the masses of the molecular partners) to μ, then with a mass change of m_1, in m_1', i.e. of μ in μ' to neglect the change of the electron energy in almost all cases; the change of the oscillation energy, on the other hand, causes in a first approximation a frequency shift of the magnitude

$$11. \qquad \Delta\nu_s = \left(\sqrt{\frac{\mu}{\mu'}} - 1\right)\nu_s$$

(ν_s = Frequenz der ursprünglichen Linie);

(ν_s = frequency of the original line);

die Aenderung der Rotationsenergie bewirkt näherungsweise eine Frequenzverschiebung um

the change of the rotational energy approximately causes a frequency shift by

$$12. \qquad \Delta\nu_{rot} = \left(\frac{\mu}{\mu'} - 1\right)\nu_{rot}$$

doch ist dieser Effekt sehr viel kleiner als der Schwingungsanteil, da ν_s sehr viel grösser als ν_{rot} ist.

but this effect is much smaller than the vibration component, because ν_s is much larger than ν_{rot}.

Zahlreiche photochemische Reaktionen werden durch optische Anregung eines der an ihnen beteiligten Moleküle ausgelöst. Verwendet man zur Anregung eine Linie, die nur von einem der isotopisch verschiedenen Moleküle absorbiert wird, so kann eine Trennung der Isotopen erreicht werden, wenn es gelingt, eine Abreaktion des abgespaltenen Atoms zu verhindern. W. Kuhn und H. Martin[16)] gelang nach dieser Methode eine Anreicherung des Chlorisotops ^{35}Cl unter Verwendung der photochemischen Dissoziation des Phosgens $COCl_2$, K. Zuber[17)] eine Anreicherung der Quecksilberisotope nach der photochemischen Reaktion $(Hg + h\nu) + O_2 = HgO + O$.

Numerous photochemical reactions are triggered by optical excitation of one of the molecules involved. If a line is used for excitation which is only absorbed by one of the isotopically different molecules, a separation of the isotopes can be achieved if it is possible to prevent an abreaction of the split atom. W. Kuhn and H. Martin[16)] succeeded in enriching the chlorine isotope ^{35}Cl with this method using the photochemical dissociation of phosgene $COCl_2$, K. Zuber[17)] enriched the mercury isotopes using the photochemical reaction $(Hg + h\nu) + O_2 = HgO + O$.

16) W. Kuhn u. H. Martin, Z. phys. Chem. (B) 21, 93 (1933)

17) K. Zuber, Helvet. phys. Acta 9, 285 (1936)

[From 1930 onward, papers such as those above demonstrated that a finely tuned metal plasma lamp could emit intense light of just the right wavelength to separate isotopes of that same type of metal, such as a mercury plasma lamp to separate mercury isotopes. In principle, a uranium plasma lamp could similarly be used to separate uranium isotopes, and it appears that there was significant wartime research in Germany to investigate that possibility. See the brief discussion in the Farm Hall transcripts about a photochemical process to enrich uranium (p. 3339).

In practice, a uranium plasma lamp probably would have consumed too much electrical power and produced too little light at just the right wavelength to be suitable for industrial-scale uranium isotope separation. Thus if there was any large-scale uranium isotope separation in the wartime German nuclear program, it probably relied on one or more of the methods covered in previous sections: centrifugation, electromagnetic separation, isotope sluice, and gaseous diffusion.

Nonetheless, this 1930s–1940s research in the German-speaking world on photochemical methods of isotope separation, together with research toward the development of lasers that was being conducted at the same time in the German-speaking world (Section C.3), was transferred to other countries during and after the war, and ultimately led to successful laser isotope separation programs decades later (p. 5127). For more information on the history, see:

D.4.6 Possible Locations of Uranium Enrichment Facilities

[In order to enrich enough uranium to a high enough concentration of uranium-235 for a bomb, it would have been necessary to have not just one enrichment unit (a centrifuge, electromagnetic separator, isotope sluice, or gaseous diffusion cell), but a large number of them operating in parallel and/or in series. Presumably after a prototype enrichment unit had been developed and proven to be satisfactory in small-scale laboratory experiments, the unit would have been mass-produced. The mass-produced units would have been set up in a new location with more room and better security.

The United States conducted its corresponding work at one massive facility in Oak Ridge, Tennessee. Proponents of the conventional view that Germany did not have a nuclear weapons program emphasize the apparent absence of an Oak-Ridge-like facility in wartime Germany. However, there are many counterarguments that must be considered:

- Oak Ridge enriched enough uranium for a gun-type bomb (Little Boy) that did not compress the uranium, was thus highly inefficient, and required ~64 kg of ~80% uranium-235. In contrast, as shown in Section D.8, the German atomic bomb was apparently a spherical implosion design (like the U.S. Gadget/Fat Man), which would have been much more efficient and would have required far less uranium ($\leq$ 10 kg). Therefore the German bomb program would have needed a far smaller production capacity than Oak Ridge.

- To minimize the risk that Allied bombing could destroy the whole program, German uranium enrichment would have been distributed among many different small sites, not concentrated in one large target. Indeed, that is exactly what was done, according to a declassified October 1944 OSS report based on information from Adolf Schneider, a senior manager of the Deutsche Waffen und Munitions-Fabrik (pp. 4400–4403).

- Any uranium enrichment conducted in the final years of the war would probably have been underground, like most other major German manufacturing. Being underground would have made it much easier for Germans to hide the enrichment facilities from Allied aerial surveillance during the war, and from Allied ground troops at the end of the war (by blowing up the entrances to the underground facilities).

- As shown in this section, primary source documents mentioned many different installations whose puzzling characteristics suggested that they might have been uranium enrichment facilities. Most of these documents ended up in the foreign intelligence files of the U.S. Manhattan Project, which means that Manhattan Project officials also thought these locations sounded like potential uranium enrichment facilities.

- Most of these potential uranium enrichment facilities were in areas of the Third Reich that ended up being occupied and stripped bare by Soviet forces, without western Allies ever having had the chance to study them.

- Even if some or all of the specific facilities mentioned in these documents were not doing nuclear-related work, they serve as excellent examples of how widespread, how sophisticated, and how secret German wartime industrial and weapons programs were, and how little we know about them to this day. Under these circumstances, it is difficult to rule out the possibility of nuclear-weapons-related production plants operating somewhere within the Third Reich, even if we cannot rule them in by pointing to their exact locations right now.

Figure D.256: Sites of possible enrichment facilities for the German nuclear program.

Some locations that may have been involved in uranium enrichment or other nuclear-related work include (see maps on pp. 3671 and 2086–2099):

Sites now in Germany:

- Berlin area, numerous locations (pp. 3438–3439, 3461–3463, 3608–3617, 3688, 3708–3709, 3926–3928, 4068, 4635–4639) [Hayes 2004; Nagel 2016].
- Bitterfeld, I.G. Farben facilities (pp. 3492–3493, 4050–4051, 4110, 4128, 4133–4137) [Karlsch 2005, p. 110; Sadovsky 2011b].
- Braunschweig, Buchler (pp. 3420, 3430–3431, 3458, 3460–3463, 3465, 4980).
- Dresden (pp. 3423, 3426, 4305, 4507).
- Erzgebirge, SS facility (p. 3708).
- Espelkamp [Preuss and Eitelberg 2003].
- Essen, Krupp (pp. 3458, 3461–3463, 3465–3467]).
- Frankfurt/Griesheim area, Degussa, Radium-Chemie, I.G. Farben, and other facilities (pp. 3440–3441, 3458, 3461–3465, 3678–3680, 4066–4067) [Hayes 2004; Nagel 2016].
- Freiburg-im-Breisgau/Feldberg area (pp. 3512–3540, 3681, 3696).
- Göttingen (pp. 3542–3544).
- Halle, I.G. Farben facilities (pp. 4052–4055).
- Hamburg area (pp. 3458, 3461–3463, 3465, 3494–3516, 4056–4061).
- Heinschenwall (pp. 3682–3683).
- Hohenzollern castle (p. 3696).
- Johanngeorgenstadt/Schneeberg/Freiberg area, Saxony (pp. 3416, 3424, 3426–3428, 3433–3437, 3445, 3456, 3468–3469, 3708, 4922) [Zeman and Karlsch 2008].
- Kaufering/Landsberg (p. 3692).
- Kiel (pp. 3494–3515).
- Koralle, north of Berlin (p. 3694).
- Lehesten (pp. 3689, 3696, 4080).
- Leuna, I.G. Farben facilities (pp. 4042–4050).
- Leverkusen, I.G. Farben facility (pp. 3488–3489, 3934–3935).
- Lübeck, Dräger Werke (pp. 4062–4063).
- Lüneburger Heide area, south of Hamburg (pp. 4176–4182, 4406).

- Müggenberg (pp. 4064–4065).
- Mühldorf (p. 3689).
- Munich area universities, research institutes, and industry (pp. 3498–3507, 4068).
- Neustadt an der Orla (pp. 3633–3638, 5052, 5055–5057).
- Nordhausen area (pp. 5289–5294).
- Oranienburg (pp. 3446, 3458, 3461–3463, 3465, 4180, 4182, 4980) [Nagel 2016].
- Peenemünde (p. 3696).
- Piesteritz, near Wittenberg (pp. 4082, 4452–4453).
- Regensburg vicinity, I.G. Farben facility (p. 3694).
- Rügen island (pp. 4390–4435).
- Saalfeld (p. 3689).
- Stassfurt vicinity, Salzbergwerke (p. 3697).
- Sigmaringen (p. 3696).
- Tegernsee (p. 3696).
- Thuringia, numerous facilities (pp. 3468–3469, 3708–3709, 3854–3868, 4436–4438, 4478–4571, 4635–4639) [Hayes 2004; Nagel 2016; Zeman and Karlsch 2008].
- Tübingen (p. 3696).
- Unterraderach/Friedrichshafen area (pp. 3921–3925).
- Villingen-Schwenningen am Neckar, W. Maier KG Radiumchemische Industrie und Laboratorium [Oleynikov 2000].
- Wittingen, W. de Boer (pp. 3458, 3461–3463, 3465).
- Zellendorf (p. 3694).
- Zeuthen-Miersdorf, near Berlin (p. 3608).
- Other possible sites in Germany?

Sites now in Austria:

- Althofen: Treibacher Chemische Werke (pp. 3420, 3432–3437, 3458, 3460, 4980) [Gollmann 1994].
- Ebensee (pp. 3718–3741, 5297–5299).
- Graz (pp. 4611–4612).
- Linz (pp. 3877–3880).

- Lofer (p. 4974).
- Melk vicinity or associated sites, underground facilities that were part of the Quarz development (pp. 3732, 4078–4079)) [Schmitzberger 2004].
- Redl Zipf/Voecklamarkt/Voecklabruck area (pp. 3718–3741).
- Rheinfelden, Degussa plant on Drau river (pp. 4080–4081).
- Stadl Paura (pp. 3718–3741).
- Steyr.
- St. Georgen/Gusen/Langenstein area (e.g., pp. 3874–3920 and 4962–4970).
- Vienna area universities, research institutes, and industry, including Floridsdorf (e.g., p. 3696).
- Weer, near Wattens, Tyrol (pp. 4072–4077).
- Weissenstein, Austrian Chemical Works plant on Drau river (pp. 4080–4081).
- Wiener Neustadt vicinity, underground facility (pp. 3732, 3748).
- Zell-am-See (p. 4788).
- Other possibles sites in Austria (pp. 3490–3491)?

Sites now in Poland:

- Baltic coast/Pomerania, many military test ranges (p. 4396).
- Bydgoszcz/Bromberg, underground facility (p. 4456).
- Gdansk/Danzig, uranium enrichment (pp. 3560, 4406, 4521).
- Oświęcim/Auschwitz area (pp. 4069, 4443–4477) large I.G. Farben facility (including heavy water plant), and nearby Auergesellschaft uranium facility at Katowice/Kattowitz.
- Poznan/Posen (pp. 2562–2575, 3245–3246).
- “Riese” area of Silesia (pp. 3328, 3424, 3429, 3445, 3471, 3712–3714, 4069, 4504–4519).
- Tuchola Forest/Tucheler Heide (p. 4902).
- Wrocław/Breslau (pp. 3712–3714, 4070–4071, 4316–4317, 4522).
- Other possibles sites in Poland?

Sites now in the Czech Republic:[11]

- Brno/Brünn (pp. 3694, 3997).
- Čelakovice/Tschelakowitz cyclotron factory (pp. 3979–4022).

---

[11] See also Czech information on World War II sites that appear to have radioactive contamination: https://www.sekm.cz and https://kontaminace.cenia.cz

- České Budejovice/Budweis (pp. 3979–4022, 5503–5566).
- Děčín/Tetschen area, Podmokly/Bodenbach/Krizik Works/Weserwerke (pp. 3936–3937, 3987–3998, 5503–5566).
- Durrnaul near Mariánské Lázně/Marienbad (p. 3424).
- Jáchymov/St. Joachimsthal area (pp. 3418–3429, 3445, 3469–3470, 3998, 4978–4984) [Hayes 2004, pp. 132–133, 235, 243].
- Liberec/Reichenberg and Jablonec/Gablonz area, Bedrichov/Friedrichsthal/Benesov nad Ploucnici and numerous other high-tech production facilities (pp. 3979–4022, 5503–5566).
- Litoměřice/Leitmeritz, Richard I, II, and III underground factories (p. 3689).
- Mladkov/Wichstadt (p. 3425).
- Opava/Tropau, I.G. Farben production plant (p. 3748).
- Ostrava/Ostrau and Vitkovice/Witkowitz, I.G. Farben and other industrial production plants (pp. 3748, 3979–4022, 5503–5566).
- Pardubice/Pardubitz/Wesser (pp. 3446, 4082–4083).
- Plzeň/Pilsen (p. 4974).
- Prague/Praha/Prag universities and other laboratories (pp. 3979–4022, 5503–5566).
- Příbram/Przibram/Pibrans (pp. 3423–3424, 3470, 3751–3754, 4921, 5696).
- Štěchovice/Stechowitz area, Blaumeise underground facilities (pp. 3755–3782).
- Other possible sites in the Czech Republic (pp. 3770–3771, 3979–4022, 5503–5566)?

Sites now in Slovakia:

- Dubnica/Dubnitz, Skoda underground facility (pp. 3784–3785).
- Other possible sites in Slovakia?

Sites now in Hungary:

- Sopron (pp. 3746–3747).
- Other possible sites in Hungary?

Sites now in Russia:

- Kaliningrad/Königsberg area, East Prussia (pp. 3928–3933).
- Other possible sites now in Russia?

Sites now in Denmark:

- Bornholm island (pp. 3786–3793).

- Other possible sites in Denmark?

Sites now in Belgium:

- Union Minière in Brussels or other locations (pp. 3335, 3408–3414) [Irving 1967, p. 65].
- Other possible sites in Belgium?

Sites now in Norway:

- Vemork (pp. 4031–4039).
- Såheim (p. 4040).
- Notodden (p. 4041).
- Trondheim (pp. 4404, 4436, 5011, 5034).
- Oslo area (pp. 5190–5198).
- Other possible sites in Norway?

Sites now in France:

- Génissiat area (pp. 3710–3711).
- Other possible sites in France?

Sites now in Italy:

- Montecatini plant, Sinigo-Merano, Italy (p. 4069).
- Montecatini plant, Cotrone/Crotone, Italy (p. 4069).
- Other possible sites in Italy?

Sites now in the Netherlands:

- Eindhoven (pp. 3976–3978, 4314–4318, 4832–4853).
- Other possible sites in the Netherlands?

Sites now in Switzerland:

- Factories producing uranium gas centrifuges for export to Germany (pp. 3545–3548).
- Other possible sites in Switzerland?

Sites now in Romania:

- Băiţa-Plai (pp. 3449–3455, 3471).
- Other possible sites in Romania?

Sites now in Bulgaria:

- Sofia area (pp. 3446, 3470, 4588) [Hayes 2004, p. 235; https://ejatlas.org/conflict/life-after-the-uranium-mines-in-buhovo-bulgaria].
- Other possible sites in Bulgaria?

Miscellaneous sites:

- Facilities run by or involving AEG.
- Facilities run by or involving Siemens.
- Other facilities run by or involving I.G. Farben (pp. 3488–3489, 3492–3493, 3678–3680, 3748–3750, 4440–4477) [Mader 1965, pp. 193–202].
- Other facilities run by or involving Degussa.
- Other facilities run by or involving Auer.
- Other facilities run by or involving the SS.
- Other facilities run by or involving the Reichspost.
- Other facilities run by or involving the Heereswaffenamt.
- Other facilities run by or involving the Luftwaffe.
- Other facilities run by or involving the Kriegsmarine.
- Other facilities run by or involving the Organisation Todt.
- Other possible sites?

All of these possible nuclear weapons production sites (and any other candidate sites that can be identified) should be investigated further. Hopefully additional documents could be found that would elucidate whether these sites conducted nuclear or non-nuclear work. If there is significant documentary evidence that a site may have done nuclear work, and if there is reason to believe that that work may have left measurable traces, industrial archaeology should be conducted at that site to measure isotopes, search for remaining pieces of equipment, or identify other evidence.

As already mentioned, the large number, size, and sophistication of all of these sites, and how little information scholars currently have about them, should at the very least emphasize (1) how vast wartime German R&D programs were, (2) how little we still know about some of them, and (3) how unwise it would be for historians currently to categorically state that there was no nuclear-weapons-related development and production anywhere in the Third Reich.]

Known/Reported Sites Now in Germany

[In addition to the sites specifically mentioned in this section, documents elsewhere throughout this appendix name a large number of other sites in Germany that were known or suspected to be conducting nuclear-related work.]

Summary of Bacteriological/Chemical Warfare in Axis Europe. Supp. Report #2. 11 March 1944. [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)] See document photo on p. 3679.

Southern Bavaria is believed to be the location of the first trials of a new German explosive, manufactured by I. G. Farben and said to be another of Germany's secret weapons. Griesheim is reported to be the location of the I. G. Farben plant where the new explosive is being manufactured. Difficulties have been encountered in its production on required scale owing to the scarcity of the "raw materials required for preparation of two of the constituent compounds."

Further experiments on another of Germany's secret weapons are now being conducted in the neighborhood of Semmering, Germany.

Vienna is said to be an important research center in Germany.

[See document photos on pp. 3679–3680.

This 11 March 1944 intelligence report mentioned planned tests of a new type of German bomb using rare materials that were manufactured (among other places) at I.G. Farben Griesheim.

Independently, it was reported that Griesheim was producing heavy water (pp. 4066–4067).

The Griesheim plant appears to have been occupied and tightly controlled by the U.S. military for nearly a year and a half after the war. See for example:

https://de.wikipedia.org/wiki/Chemische_Fabrik_Griesheim-Elektron

and sources cited therein.]

SECRET

SUMMARY OF

BACTERIOLOGICAL/CHEMICAL WARFARE

IN AXIS EUROPE

Supp. Report #2

MAR 11, 1944

This report deals principally with plants in Germany and in German-occupied territory having bacteriological capabilities, as well as with leading civilian and military personalities connected with these plants or with bacteriological research.

The report contains nothing of interest to us in the way of scientific personnel but several locations mentioned in connection with research, experimentation and manufacture may be of some interest.

Southern Bavaria is believed to be the location of the first trials of a new German explosive, manufactured by I. G. Farben and said to be another of Germany's secret weapons. Griesheim is reported to be the location of the I. G. Farben plant where the new explosive is being manufactured. Difficulties have been encountered in its production on required scale owing to the scarcity of the "raw materials required for preparation of two of the constituent compounds."

Further experiments on another of Germany's secret weapons are now being conducted in the neighborhood of Semmering, Germany.

Vienna is said to be an important research center in Germany.

Figure D.257: This 11 March 1944 intelligence report mentioned planned tests of a new type of German bomb using rare materials that were manufactured (among other places) at I.G. Farben Griesheim [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]. See also pp. 4066–4067.

SECRET
By authority A. C. of S., G-2,

Date 5 MAY 44 (SLC)
Initials

Information on a secret German underground rocket factory obtained from an Infantry Private captured in Tunisia 7 May 1943. Information received in the U.S. 4 May 1944.

The factory is located according to the prisoner, 1 km. N.W. of Feldberg in Baden. Coordinates of Feldberg are: 47.52 N, 8.2 E.

Information has not been verified by other sources, and should not be accepted at face value.

The prisoner's brother-in-law worked at this secret establishment for some time during the winter of 1940-41, and it is from him that the prisoner derived all information below not specified as his own at first hand.

The prisoner was first told by his brother-in-law that very important work was being conducted at the factory which if it turned out well would change the whole aspect of the war for the Germans. At this time he added no further details beyond saying that it was concerned with new explosives and ray weapons. At some point in the winter of 1940-41 he went a little further declaring that the object in view was to produce a terrifically effective liquid explosive. The investigations were already far advanced but had not yet attained precisely what the investigators were looking for. It was, however, his belief that an explosive had even then been developed so powerful that it put all others in the shade. Work was likewise in progress on a television instrument for projectiles, which was to be fitted to the rocket missiles the Germans were developing if it proved successful. At that stage the only difficulty with these rockets, otherwise very satisfactory, was that they did not yet have an adequate range but, in the opinion of prisoner's informant, this was a matter which depended only on the explosive propellant which was exactly what the Germans were endeavoring to improve. In connection with the explosive itself, it was found difficult to store it in very large quantities as it detonated immediately on contact with oxygen. Hence, both the explosive as such had to be stored, and the projectiles loaded with it, in chambers entirely free of air. (It is not explained how any workers could have breathed during the loading of the projectiles under the circumstances, but perhaps the process was entirely mechanical- Editors Note).

In the Spring of 1941 the prisoner's brother-in-law made an attempt to get permission for the prisoner to attend certain important tests which were to be held the following summer but he was unable to do so. He also then told the prisoner more about the television instrument above mentioned. It was to have a beryllium casing..All kinds of other alloys had been tried for this purpose but until beryllium was used nothing worked. The inner circumference of the instrument was 37 cm. and about one fifth of its internal space was occupied by the mechanism. 26 meters of platinum wire were used in the instrument. It was fitted with twelve photographic eyes, of which the openings sloped at an angle forward.

No fears were entertained that the instrument might fall into enemy hands only slightly damaged, because it would automatically be blown to pieces as soon as it came within 150 m. of the ground.

SECRET

1231 Page 2

The ignition for the explosive charge by means of which this was accomplished operated by a system based on terrestrial magnetism.

During the summer of 1941 the prisoner was informed that the explosive to be employed both in the bursting and propellant charges of the rocket projectiles had been finally perfected. It was designated K.Z.O. and was also to be used in new artillery projectiles. A new 125 mm. twin gun had been constructed for that purpose. The barrels for this weapon had to be much stronger than those of an ordinary cannon. They were also somewhat longer. The shells were intended for use as AA, and were capable of reaching a height of 16,000 meters. They had very great explosive force.

Experiments with rocket projectiles went on through the fall of 1941 and the succeeding winter. They achieved a high degree of success. Most of them took place on the Lueneburger Heide. On one occasion some were carried out at the Krupp artillery proving grounds. By the summer of 1942 it was stated to the prisoner that a range of 800 km. could be attained with the rocket projectile. The one then in use had a 15 cm. calibre. The range mentioned was really only reached late in the autumn of 1942. The later experiments involved did not occur on the Lueneburger Heide. At what exact location they were conducted the prisoner does not know, but he was informed that it was somewhere in the North and the rockets were aimed toward Norway. He was not told in just what area they fell.

The last information which the prisoner received from his brother-in-law dates from May 1943. It was to the effect that tests were about to be made with 52-cm. rocket projectiles. The informant then estimated that at earliest the projectiles would come into practical use by the summer of 1944. Great pressure is being exercised in the conversion of industries to produce this new weapon, but, the informant wrote "all good things take time". He likewise estimated that the twin 125 mm. cannon above would be used in the field about November or December, 1943.

From his personal knowledge of his brother-in-law the prisoner is convinced in his own mind that he was not telling lies. He goes on to state (apparently on his own authority) that ever since the summer of 1941 the personnel employed on the above projects have from time to time been sent for their health to a hotel in St. Georgen located a few km. West of Villingen, but not the one on the S.W. edge of Freiburg-in-Breisgau. The prisoner is not certain of the precise identity of the hotel but believes it to be one which is not very well-known. When the personnel go there it is under Gestapo supervision and they are allowed to talk to nobody. There is also a "home" for them somewhere, but all the prisoner knows about it is its existence.

What follows is the prisoner's account of his own visit to the establishment already in part described in the autumn of 1941. He calls it "Kriegslaboratorium"(war laboratory).

The prisoner was met at Freiburg-in-Breisgau by his brother-in-law. They then drove for twenty minutes in a car, stopping in a young forest, where the car was driven into one of several very well camouflaged garages. The prisoner says that if they had not been pointed out to him he would never have believed that there were any garages there. It is his belief that an entrance (presumably underground - Editor's Note) led all the way from the place where they stopped to the laboratory, but he can give no definite information on this subject. In any case, after stopping they walked for two hours. He asked whether it was always necessary to do this in order to reach the laboratory. His brother-in-law laughed at him and a Gestapo agent who accompanied them told him not to be so curious.

SECRET

1231 Page 3

He did not enter what he calls the "Feldberghaus" itself, which his brother-in-law told him was the headquarters of the entire project. Instead they went into a hut which from the outside was exactly like a large hunting lodge. In reality it was the entrance to an elevator. Outside the height of the hut was about 5 or 6 meters but inside steps went down for some 9 meters. At this point a gallery led off but the prisoner knows neither where it went nor anything else about it. They then went down in an elevator, for about twenty meters, according to another Gestapo man who was with them. Here the prisoner was shown the process by which the explosive was drawn off into flasks made of steel, and from then again into still smaller ones. He was supposed to make up his mind whether the "shut-off" apparatus" could be used for torpedoes. In his opinion it could not.

In another room he was shown various explosive projectiles. Steel capsules were here filled with different explosives of which he does not remember the names. The walls of these capsules were 3 cm. thick. None of the types of explosive first used could burst them. Next, two of the capsules were filled with K.Z.O., and the charge ignited. Both burst.

The prisoner then asked to be taken to the storeroom. This was done. They went down to a level of 40 meters, (below the surface? or below the point they had already reached?- Editor's Note). Then they traveled about a kilometer on a level ~~track~~ R.R. They next transferred to another car and traveled a further 2½ km. in a slightly downward direction until they had reached a floor level of 72 meters. The prisoner does not know in what direction they traveled.

The corridor to which they finally came, he estimates to have been about 300 meters long. From it storerooms opened. They then entered a room in which they put on rubber suits which shut them off completely from the air. Afterwards they went into a second room which proved to be only an anti-chamber. When the door had been shut the prisoner states that the air was entirely pumped out of this room, but this he said he did not learn until he got back to the railroad station. They remained in the anti-chamber for approximately ten minutes. The door of the actual storeroom was then opened. In it were kept uncovered containers filled with explosive.

When they were once more outside and had taken off their rubber suits there was a discussion. One of the men said to the prisoner, who seems at that time to have been working with torpedoes,"You are going into the water and we into the air." As this remark was rather puzzling, another man added: "Of course, torpedoes for you and rockets for us." The prisoner felt that he had better conceal from them quite how much he knew already about their activities, so he merely murmured: "Oh yes, storm-rockets." One of the previous speakers looked at him, and then telling him to follow, led him into the room where the rockets were stored. This room was not air-free. He was not allowed to get very near the rockets nor to stay in the room for more than two minutes. The rocket projectiles he saw were, he thinks, about 230 cm. long.

They then returned by the same way they had come. He had been in the establishment, all told, about four hours. One individual whom he mentions having seen there was a Doctor Ernst. Before he left he was obliged to sign a paper to the effect that everything which he had seen or heard in this place was a state secret and that to reveal any of it was an offense punishable with death. The Gestapo agents stayed at the railroad station. He later learned that a good many of them were kept on duty in that vicinity.

SECRET

1231 Page 4

In a subsequent talk the prisoner's brother-in-law observed that he was convinced provisions had been made for the work to be continued elsewhere should there by misfortune be an accident with the explosive which destroyed the actual establishment. But he had no idea where the alternative site might be situated. He also told the prisoner that the villages adjacent to the underground factory, where its workers lived, had been bought up some time before. The fields were farmed by the families of the Gestapo men in order not to attract notice by their being left unplanted. He believed that well-trained police dogs were used in the area and that these animals were such as had been employed for similar purposes over many years in Germany or abroad. The entire district was infested with individuals who seemed to be tramps but who were really Gestapo agents. He thought that there were beside various technical security measures, but was ignorant of their nature. In fact, he did not think that there was any single person who knew them all. He believed it more probable that each man was familiar with only one security measure. It was his idea that, when it was considered perfect security had been assured for the project, the area would again be opened to the public. In that case the personnel would have to get out of the Feldberghaus. He knew at least that a new house was being built to the N.W. of this structure, however, he was not aware for what purpose it was intended. Neither could he supply any information about how and when the building of the laboratory had been begun, except that it was his impression that this had taken place in connection with the work on the Western frontier defenses. He asserted that it had not been necessary to carry all the material underground on the elevator which the prisoner saw, saying that other entrances and exits existed for that sort of thing. However, he did not say where they were, observing merely that they were well-placed. Nor did he make any statement about the transportation of materials.

In the Autumn of 1941 the prisoner again met Dr. Ernst, above mentioned, at some kind of a meeting in Magdeburg. The talk turned to the war and the weapons with which it was fought. This led Ernst to put forward the claim that if he was successful in his experiments with certain rays, to which he owed the mutilation of one of his hands, the war would be won. He was convinced that the enemy could find no way of counteracting the effect of the rays, and that they would kill an immense number of men. He spoke too of rays which were to be used against planes. But he gave no additional details whatever about either kind of ray.

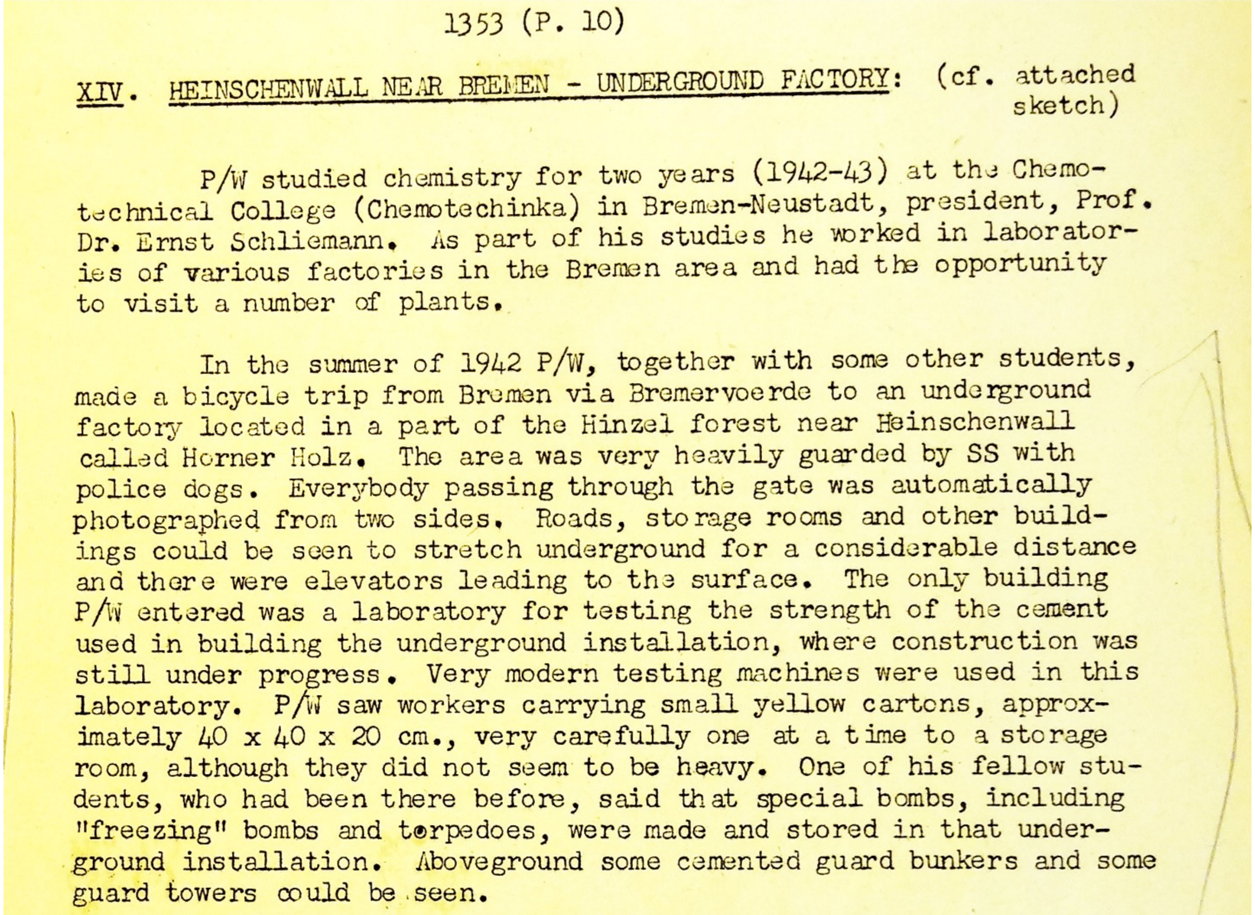
REPORT FROM CAPTURED PERSONNEL AND MATERIAL BRANCH

Information from several German army Ps/W captured in France in August 1944 and two Ps/W captured in Italy in June and July 1944. Obtained in the U. S. 13 - 16 October 1944. Believed reliable, not verified from other sources.



1353 (P. 10)

XIV. HEINSCHENWALL NEAR BREMEN - UNDERGROUND FACTORY: (cf. attached sketch)

P/W studied chemistry for two years (1942-43) at the Chemotechnical College (Chemotechinka) in Bremen-Neustadt, president, Prof. Dr. Ernst Schliemann. As part of his studies he worked in laboratories of various factories in the Bremen area and had the opportunity to visit a number of plants.

In the summer of 1942 P/W, together with some other students, made a bicycle trip from Bremen via Bremervoerde to an underground factory located in a part of the Hinzel forest near Heinschenwall called Horner Holz. The area was very heavily guarded by SS with police dogs. Everybody passing through the gate was automatically photographed from two sides. Roads, storage rooms and other buildings could be seen to stretch underground for a considerable distance and there were elevators leading to the surface. The only building P/W entered was a laboratory for testing the strength of the cement used in building the underground installation, where construction was still under progress. Very modern testing machines were used in this laboratory. P/W saw workers carrying small yellow cartons, approximately 40 x 40 x 20 cm., very carefully one at a time to a storage room, although they did not seem to be heavy. One of his fellow students, who had been there before, said that special bombs, including "freezing" bombs and torpedoes, were made and stored in that underground installation. Aboveground some cemented guard bunkers and some guard towers could be seen.

SECRET

MEMORANDUM FOR MAJOR R.R. FURMAN:

Subject: German Plants that might be working with Uranium.

A prel. survey of the German Chemical industry has been made for the purposes of determining possible chemical plants within Germany that are possibly engaged in the production of U. metal, and the bomb damage sustained by each, if any. Inasmuch as there are some 17,141 chemicals plants in Germany proper this survey was limited mainly to the two largest German Chemical units, namely, I. G. Farbenindustrie, A. G., and Wintershall, A. G., and to those plants that were known to have been engaged in the handling and processing of precious metals before the war. ~~Although~~ However, there was no concerted effort to determine names and localaties of all Germany's precious metal producers inasmuch as FEA has presently undertaken such an assignment at your request. ~~However,~~ A curosy examination was made of all the larger German chemical plants to the extent of the information on file in the FEA, which is very brief in respect to many of the plants.

1. I. G. FARBENINDUSTRIE, A. G.

As you know I. G. Farben is Germany's largest Chemical Combine with its headquarters in Frankfort a/m.

In some important commodity groups, plant management and commodity distribution are concentrated in many cities for attaining desirable ends of decentralization. Thus control over the pharamaceutice trade

- 1 -

SECRET

written by Calvert

SECRET

is centered in the Bayer work at Leverkusen; photographic film and rayon in the Afga headquarters in Berlin; ammonia in the Leuna plant, etc. However, general managerial control, policy, technical supervision, etc., are concentrated in Frankfort.

The larger I. G. plants are as follows:

NAME	CAPITALIZATION IN RM(millions)	RANK ORDER IN GERMANY
Ludwigshafen	300	1
(Bombed numerous times - overall destruction evaluation is D ∕)		
Leuna	135	2
(Bombed numerous times - overall destruction unestimated)		
Leverkusen	100	3
(Bombed numerous times - overall destruction unestimated)		
Elberfeld	50	8
Frankfort	60	6.1
(Bombed numerous times, the latest raids in February of which the reports are not prepared as of date. In the raids of 22 October 1943, 18 November 1943, 25 November 43, the plant sustained slight damage. Received some damage in the raid of 20 December 1943. In the USAAF raid of 29 January 1944 it sustained major damage. Overall classification of bomb damage would be "C".)		
Griesheim	60	6.2
Bitterfeld I Bitterfeld II	75	5
Rhienfeld	2	27.1
Offenbach	10	10.3
(Bombed on 20 December 1943 sustaining slight damage, probably received additional damage in bombings of February on Frankfort.)		
Premnitz	30	4
(Hadn't received any damage as of 1 February 1944.)		

The I. G. Farbenindustrie is the logical Chemical Company that would be engaged in any German operation of large scale isotope separation, if

- 2 -

SECRET

SECRET

Germany undertook such an operation. The company's experience in heavy chemicals, and, it being a Chemical combine comparable to DuPont would lead me to believe that it is the most likely company to be engaged in such production. From examination of FEA files no new large construction programs were being undertaken by I.G. other than normally building in their established plants. There was nothing on the scale anyways comparable to what is believed to be necessary for such an operation. There was one report of an installation near Brandenburg that was described as a huge plant, "secret factory." The production was not known. The plant was surrounded by huge steel fence. The plant was situated in a swampy and desolate area with few settlements. This plant could be an I.G. plant. This will be investigated further, also topographical terrain will be studied, availability of power supply, etc.

For the reason that it would almost be impossible by such methods to determine possible locations, most of the survey was directed towards those I.G. plants that had experience in Fluorine. The two main I.G. producers of hydrofluric acid are Leverkusen and Bitterfeld and would probably be the most logical location where a K-25 separation would be located provided a separate and individual plant had not been erected for such purposes, Even if there has been separate installation constructed, these plants would be the logical place for a pilot plant for a K-25 job. From RAF reconnaisance pictures there was no evidence of ~~any~~ new construction of any importance at Leverkausen. Likewise there was no new construction at Bitterfeld with the exception of one new building of app. size, 820" x 150". Utilization of this new building was not given. Both

- 3 -

SECRET

SECRET

Leverkusen and Bitterfeld have sustained rather heavy bomb damage. Bitterfeld sustaining probably the greatest damage due to the large raids on Frankfort during last month. For a detailed list of all the larger I.G. plants see attached list.

2. WINTERSHALL, A. G.

Wintershall Chemical Company is Germany's second largest Chemical company with its home office in Berlin. As a means of comparison in size with I.G., it should be pointed out that Wintershall's capitalization in RM (millions) is 112.5, while I.G.'s capitalization is 800, or in other words Wintershall in terms of capitalization is not even as large as I.G.'s biggest plant--Leuna. Wintershall's chief subsidaries are Sprengstoffwerke Kiesilebach, (50%), and Mitteldeutsche Sprengstoffwerke, Langelshiem (36%). The main products are potash, alkalies. It is the owner of a large number of potassium salt mines and plants for the milling and purification of the salts. They are also producers of nitrogen, ammonia, fertilizers (nitrogen and potassium), and nitric acid. The main plant at Rauxel, 7 miles N.W. of Dortmund. While no evidence of bomb damage to Wintershall could be found, Dortsmound has been bombed numerous times and undoubtedly Wintershall has been damaged, at least indirectly through the bombing of Dortmund. In this survey there was nothing uncovered to give the impression that Wintershall would be of interest to us more than any other large German Chemical company.

3. Refiners of precious metals and bomb damage they have sustained.

A. Deutsche Gold und Silber Scheideanstalt

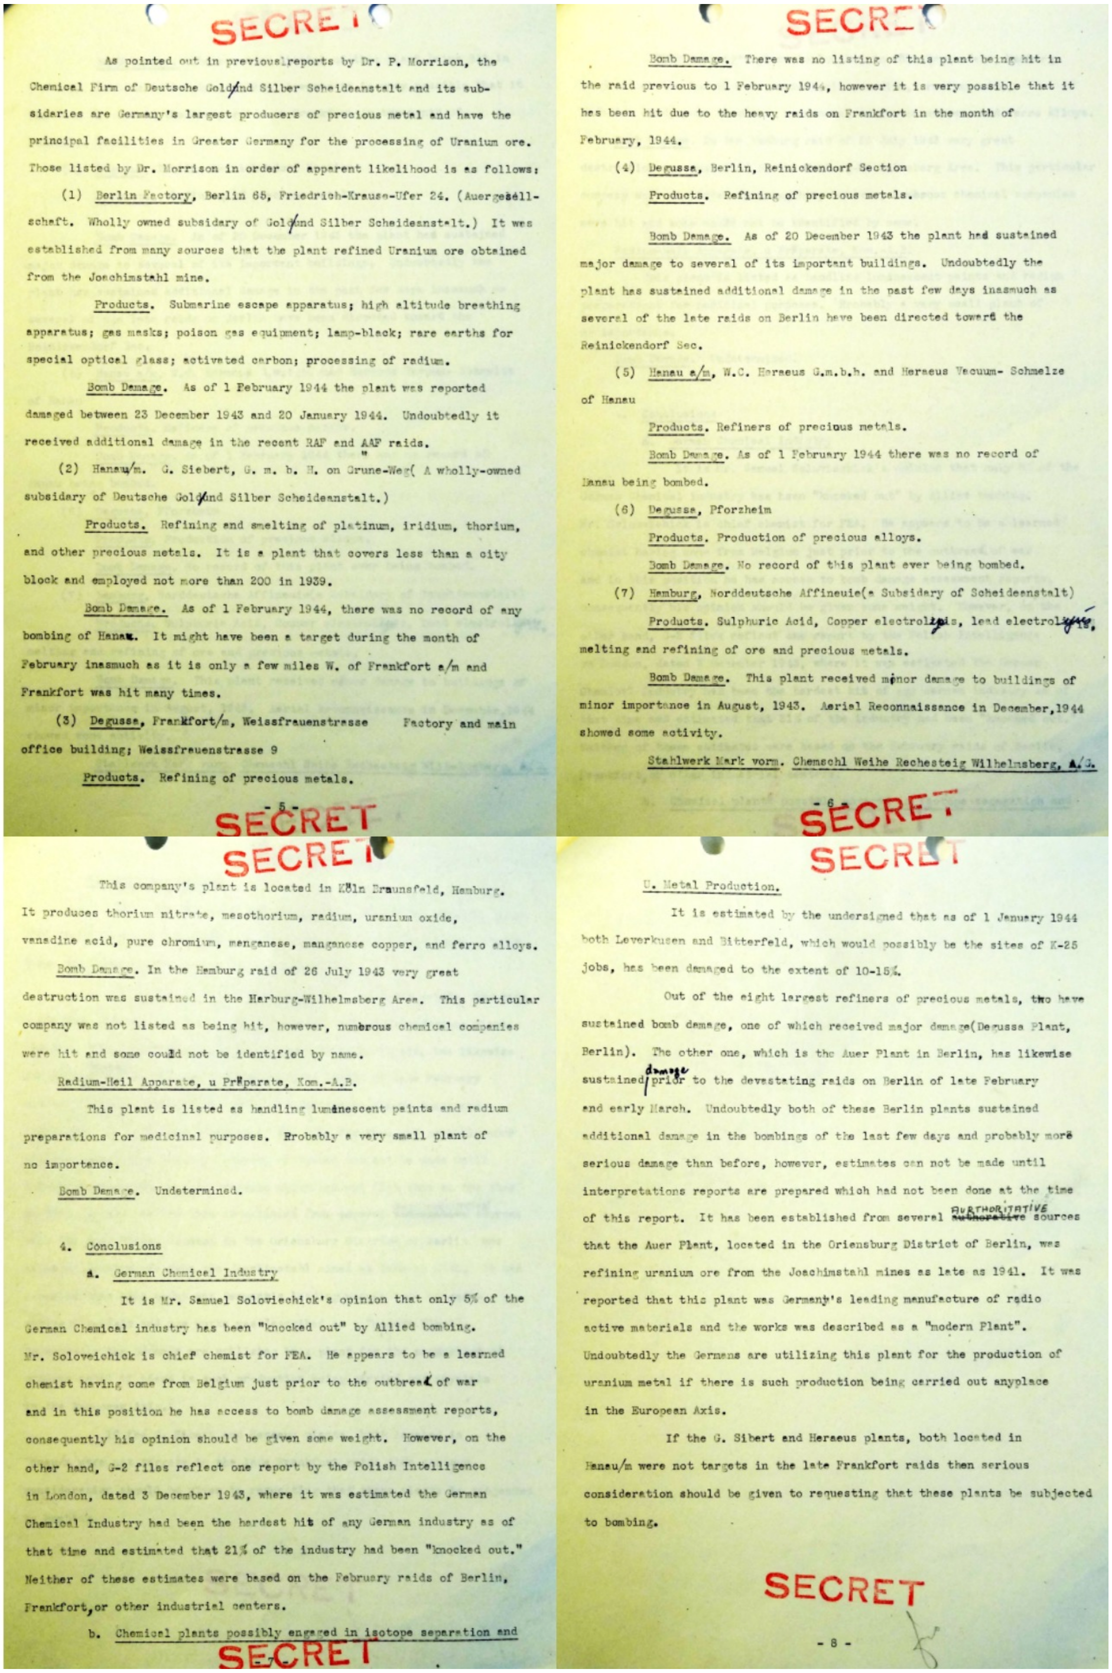
NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-1
GERMANY: US Wartime Positive Int. (July 42–June 44).
Horace Calvert to Robert Furman. Undated but apparently Feb. 1944.



SECRET

As pointed out in previous reports by Dr. P. Morrison, the Chemical Firm of Deutsche Gold/und Silber Scheideanstalt and its subsidaries are Germany's largest producers of precious metal and have the principal facilities in Greater Germany for the processing of Uranium ore. Those listed by Dr. Morrison in order of apparent likelihood is as follows:

(1) Berlin Factory, Berlin 65, Friedrich-Krause-Ufer 24. (Auergesellschaft. Wholly owned subsidary of Gold/und Silber Scheideanstalt.) It was established from many sources that the plant refined Uranium ore obtained from the Joachimstahl mine.

Products. Submarine escape apparatus; high altitude breathing apparatus; gas masks; poison gas equipment; lamp-black; rare earths for special optical glass; activated carbon; processing of radium.

Bomb Damage. As of 1 February 1944 the plant was reported damaged between 23 December 1943 and 20 January 1944. Undoubtedly it received additional damage in the recent RAF and AAF raids.

(2) Hanau/m. G. Siebert, G. m. b. H. on Grüne-Weg(A wholly-owned subsidary of Deutsche Gold/und Silber Scheideanstalt.)

Products. Refining and smelting of platinum, iridium, thorium, and other precious metals. It is a plant that covers less than a city block and employed not more than 200 in 1939.

Bomb Damage. As of 1 February 1944, there was no record of any bombing of Hanau. It might have been a target during the month of February inasmuch as it is only a few miles W. of Frankfort a/m and Frankfort was hit many times.

(3) Degussa, Frankfort/m, Weissfrauenstrasse Factory and main office building; Weissfrauenstrasse 9

Products. Refining of precious metals.

- 5 -

SECRET

SECRET

Bomb Damage. There was no listing of this plant being hit in the raid previous to 1 February 1944, however it is very possible that it has been hit due to the heavy raids on Frankfort in the month of February, 1944.

(4) Degussa, Berlin, Reinickendorf Section

Products. Refining of precious metals.

Bomb Damage. As of 20 December 1943 the plant had sustained major damage to several of its important buildings. Undoubtedly the plant has sustained additional damage in the past few days inasmuch as several of the late raids on Berlin have been directed toward the Reinickendorf Sec.

(5) Hanau a/m, W.C. Heraeus G.m.b.h. and Heraeus Vacuum- Schmelze of Hanau

Products. Refiners of precious metals.

Bomb Damage. As of 1 February 1944 there was no record of Hanau being bombed.

(6) Degussa, Pforzheim

Products. Production of precious alloys.

Bomb Damage. No record of this plant ever being bombed.

(7) Hamburg, Norddeutsche Affineuie(a Subsidary of Scheideanstalt)

Products. Sulphuric Acid, Copper electrolysis, lead electrolysis, melting and refining of ore and precious metals.

Bomb Damage. This plant received minor damage to buildings of minor importance in August, 1943. Aerial Reconnaissance in December,1944 showed some activity.

Stahlwerk Mark vorm. Chemschl Weihe Rechesteig Wilhelmsberg, A/G.

- 6 -

SECRET

SECRET

This company's plant is located in Köln Braunsfeld, Hamburg. It produces thorium nitrate, mesothorium, radium, uranium oxide, vanadine acid, pure chromium, manganese, manganese copper, and ferro alloys.

Bomb Damage. In the Hamburg raid of 26 July 1943 very great destruction was sustained in the Harburg-Wilhelmsberg Area. This particular company was not listed as being hit, however, numbrous chemical companies were hit and some could not be identified by name.

Radium-Heil Apparate, u Präparate, Kom.-A.B.

This plant is listed as handling lumanescent paints and radium preparations for medicinal purposes. Probably a very small plant of no importance.

Bomb Damage. Undetermined.

4. Conclusions

a. German Chemical Industry

It is Mr. Samuel Soloviechick's opinion that only 5% of the German Chemical industry has been "knocked out" by Allied bombing. Mr. Soloveichick is chief chemist for FEA. He appears to be a learned chemist having come from Belgium just prior to the outbreak of war and in this position he has access to bomb damage assessment reports, consequently his opinion should be given some weight. However, on the other hand, G-2 files reflect one report by the Polish Intelligence in London, dated 3 December 1943, where it was estimated the German Chemical Industry had been the hardest hit of any German industry as of that time and estimated that 21% of the industry had been "knocked out." Neither of these estimates were based on the February raids of Berlin, Frankfort, or other industrial centers.

b. Chemical plants possibly engaged in isotope separation and

- 7 -

SECRET

SECRET

U. Metal Production.

It is estimated by the undersigned that as of 1 January 1944 both Leverkusen and Bitterfeld, which would possibly be the sites of K-25 jobs, has been damaged to the extent of 10-15%.

Out of the eight largest refiners of precious metals, two have sustained bomb damage, one of which received major damage(Degussa Plant, Berlin). The other one, which is the Auer Plant in Berlin, has likewise sustained damage prior to the devastating raids on Berlin of late February and early March. Undoubtedly both of these Berlin plants sustained additional damage in the bombings of the last few days and probably more serious damage than before, however, estimates can not be made until interpretations reports are prepared which had not been done at the time of this report. It has been established from several ~~authorative~~ AUTHORITATIVE sources that the Auer Plant, located in the Oriensburg District of Berlin, was refining uranium ore from the Joachimstahl mines as late as 1941. It was reported that this plant was Germany's leading manufacture of radio active materials and the works was described as a "modern Plant". Undoubtedly the Germans are utilizing this plant for the production of uranium metal if there is such production being carried out anyplace in the European Axis.

If the G. Sibert and Heraeus plants, both located in Hanau/m were not targets in the late Frankfort raids then serious consideration should be given to requesting that these plants be subjected to bombing.

From a cable from Stockholm dated 12 April 1945 the information below is paraphrased for your use. The information is dated 7 April 1945 and is obtained from a source which is experienced in weapons, and is reliable.

1. V weapon. The German experimental station at Peenemünde has been evacuated and moved to Wilhelmshafen and Plauen according to definite information. Professor [Herbert A.] Wagner is the head of the experimental station. Rocket bomb type Hs (Henschel) 117, also called Luftgoliath, is the subject of most experiments at present. This controlled rocket bomb is a long range weapon. 8000 meters is the height to which it can be shot with precision. Is propelled vertically towards [from] the ground. This weapon can be directed into groups of enemy planes by means of remote radio control. In October 1944 at Lüneburger Heide in experiments all of a group of 12 of their own [...] remotely controlled planes sent up were shot down with only 1 shot.

4000 of the Hs 117 have now been delivered. [...]

V weapons which are grenades of flying bombs filled with an unknown gas, which is harmless in itself, are, according to vague rumors, manufactured somewhere in Germany (location unknown). When this projectile strikes, a very high pressure is developed which kills living creatures within a radius of from one to four kilometers. Even insects such as beetles are killed by the explosion according to reports. [...]

5. There is an “SS Gebiet” surrounded by double barbed wire charged with high voltage not far from Berlin, at Neunburg. 40,000 [...] forced laborers who may not leave are within this area. Some well known technicians who visit the place sometimes stay more than a week. The product manufactured here is not known. There is very strict guarding by SS, and people have been shot without warning when they wandered too near the barricade.

[There were several independent reports of nuclear-weapons-related plants in or near Lüneburger Heide (e.g., pp. 4172–4182, 4406–4407).

There were also several independent reports of nuclear-weapons-related plants in or near Berlin (e.g., pp. 3608–3617, 4635–4639).]

SUBJECT: AZUSA.

From a cable from Stockholm dated 12 April 1945 the information below is paraphrased for your use. The information is dated 7 April 1945 and is obtained from a source which is experienced in weapons, and is reliable.

1. V weapon. The German experimental station at Peenemunde has been evacuated and moved to Wilhelmshafen and Plauen according to definite information. Professor Wagener is the head of the experimental station. Rocket bomb type HS (Henscheu) 117, also called Luftgoliat, is the subject of most experiments at present. This controlled rocket bomb is a long range weapon. 8000 meters is the height to which it can be shot with precision. Is propelled vertically towards the ground. This weapon can be directed into groups of enemy planes by means of remote radio control. In October 1944 at Luneburger Heide in experiments all of a group of 12 of their own* remotely controlled planes sent up were shot down with only 1 shot.

4000 of the HS 117 have now been delivered. Production began ten days ago.

Manufacture of the HS is at Henschel Factories, Oderwerke in Nordhausen woffleben (Halle-Kassel). Entrance to mine shaft in which weapons are actually manufactured can be observed from the air. Barracks which are used as quarters for workers, offices, and construction offices are erected around the entrance. The Friedrich Listwerke in Plauen Voigtland manufactured the "Kreiseln"**(remote control arrangement) for the HS 117.

Hornwerke, Oderstrasse 26 in Berlin-Telow makes the rocket engine. Askaniawerke,*** Berlin-Kaiserallee, Friedenau also carries out various details.

Friedenau is also the center for administration for the entire V manufacture.

Figure D.264: H. W. Dix to Francis J. Smith. 14 April 1945. SUBJECT: AZUSA. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

- 2 - SECRET

V weapons which are grenades or flying bombs filled with an unknown gas, which is harmless in itself, are, according to vague rumors, manufactured somewhere in Germany (location unknown) When this projectile strikes, a very high pressure is developed which kills living creatures within a radius of from one to four kilometers. Even insects such as beetles are killed by the explosion according to reports.

2. Regarding peroxide factories. No information has been obtained from inquiries made through connections in medical circles as to whether there are any factories left in Germany or as to whether any new ones have been constructed.

3. Regarding technical magazines. A few of these, in stenciled copy form, are distributed in Germany only among leading people.

4. Essener National Zeitung is no longer issued in Germany according to information.

5. There is an "SS Gebiet" surrounded by double barbed wire charged with high voltage not far from Berlin, at Neunburg. 40,000 (sic)**** forced laborers who may not leave are within this area. Some well known technicians who visit the place sometimes stay more than a week. The product manufactured here is not known. There is very strict guarding by SS, and people have been shot without warning when they wandered too near the barricade.

* Received as owo.
** Also received as Kretseln.
*** Also received as Atkaniawerke.
**** as received.

There are two points which do not appear to shape up. The first point is the last sentence of the first paragraph of number 1. It is questionable whether all of the twelve planes could be shot down with one shot. The second point is on all of the second paragraph under number 1. The four thousand is a sizeable quantity to be made within ten days from the beginning of manufacture if the item is sizeable at all. The first paragraph of number 1 would indicate that it is of considerable size.

II INFORMATION ON POSSIBLE T A SITES

7. Saalfeld-Thüringia.

A report dated 19 April 1944 was received from OSS stating that a new weapon is being manufactured in an underground factory at SAALFELD-THÜRINGIA, Germany. The report added that experimental laboratories formerly in Berlin have been transferred to STRASBOURG and installed in a hospital there. The casings and tubings for the weapon were reported to be manufactured in the mechanical workshops in Bitschwiller (Haut-Rhin). Some significance is attached to this report because of the fact that a laboratory of interest to us has been discovered in a hospital in Strasbourg. Air coverage of the Saalfeld area has been obtained and is now being studied. [...]

10. Leitmeritz.

An ungraded report indicated that the production of precision instruments for V-3 is being carried on by the Germans in the town of LEITMERITZ in Sudetenland. According to this report, a large volume of electric power is being directed to the factory. A power survey and aerial coverage of the area have been obtained and are being forwarded to General Groves' office for review.

11. LEHESTEN.

An OSS report states that possible manufacture of long range projectiles is being carried on in a semi-underground installation about 1.5 K.M. north of Lehesten in Germany. T A interest in the report arises from the fact that Siemens and Halske are said to be in charge of the plant, and a reference to the breaking down of water by electrolysis at this site. Aerial coverage has been requested.

[See document photos on pp. 4764–4765.]

Monthly Intelligence Summary. March 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

k. Air photos of a German plant at Muhldorf were forwarded to Major Smith for submission to Dr. Morrison. Interpreters on this side were unable to establish what sort of work was being pursued here.

SECRET — 5TH ARMY POW CAGE (Air) — Target Notes A/16
7th November 1944

1. **Preamble** The following information was obtained from a reasonably intelligent and cooperative P/W. He claims that he deserted at the first opportunity and makes every effort to be accurate and helpful. His information may be considered reliable and dates from his most recent furlough in June 1944. He has been sent to CSDIC (Air) Rome for detailed interrogation.

2. **Underground Jet-Propelled A/C Factory, Kloster/Lechfeld — Kaufering** In June 1944 approximately 20,000 workers began excavation and construction under Organization TODT on underground work-shops which P/W estimates to be ten in all. Some of these were already partially dug when he saw them in June 1944. P/W describes their size as 25 meters deep, 100 meters long, and 60 meters wide. The depth he describes as being that at which he saw the excavations. He assumes that they were intended to be deeper. The holes were spaced in a straight line about 200 meters apart. P/W recalls seeing one being dug some distance away from this line and claims that others were being dug in the woods west of KAUFERING.

3. Work was begun simultaneously on all but the ones nearest KAUFERING were closer to completion. When the holes exceeded 6 meters in depth camouflaging netting was placed over them. Guards with watch-dogs were on duty about the area whose dual purpose was both to keep the workers in the area and the civilians out. Barbed-wire entanglements were also erected.

4. From KLOSTER/LECHFELD three RR sidings were laid to HURLACH (48 degrees 7' 30"N—10 degrees 50'00"E), where the freight depot was being enlarged. This depot was the main RR center for the underground activity.

5. The head architect of the operation, a Herr ANTON LICHTENSTEIN, told P/W that "Turbine Jäger" (Jet-Propelled Air-craft) were to be manufactured here. LICHTENSTEIN's offices were located at MÜNCHER STRASSE 9, LANDSBERG.

6. These excavations were located between KLOSTER/LECHFELD and KAUFERING in the area bounded by 48 degrees 05'30"N—10 degrees 49'30"E and 48 degrees 08' 30"N—10 degrees 49' 00"E. P/W describes the area as being west of the main highway between AUGSBURG and LANDSBERG, west of the river LECH, and 250 meters west of the small RR line from LECHFELD to KAUFERING.

7. **Other Underground Factories** P/W claims that a number of underground factories are located between LANDSBERG and SCHONGAU on the west side of the RR line and main highway in a heavily wooded area. P/W did not know what was to be built or whether they were already in operation. He knew, however that were similarly constructed as the above (See paragraph 2). He had his information from members of Organization TODT, who had helped with construction there.

8. **Electric Powers Stations, LANDSBERG — SCHONGAU** Along the river LECH between LANDSBERG and SCHONGAU four electric power stations are located. Their approximate coordinates are:

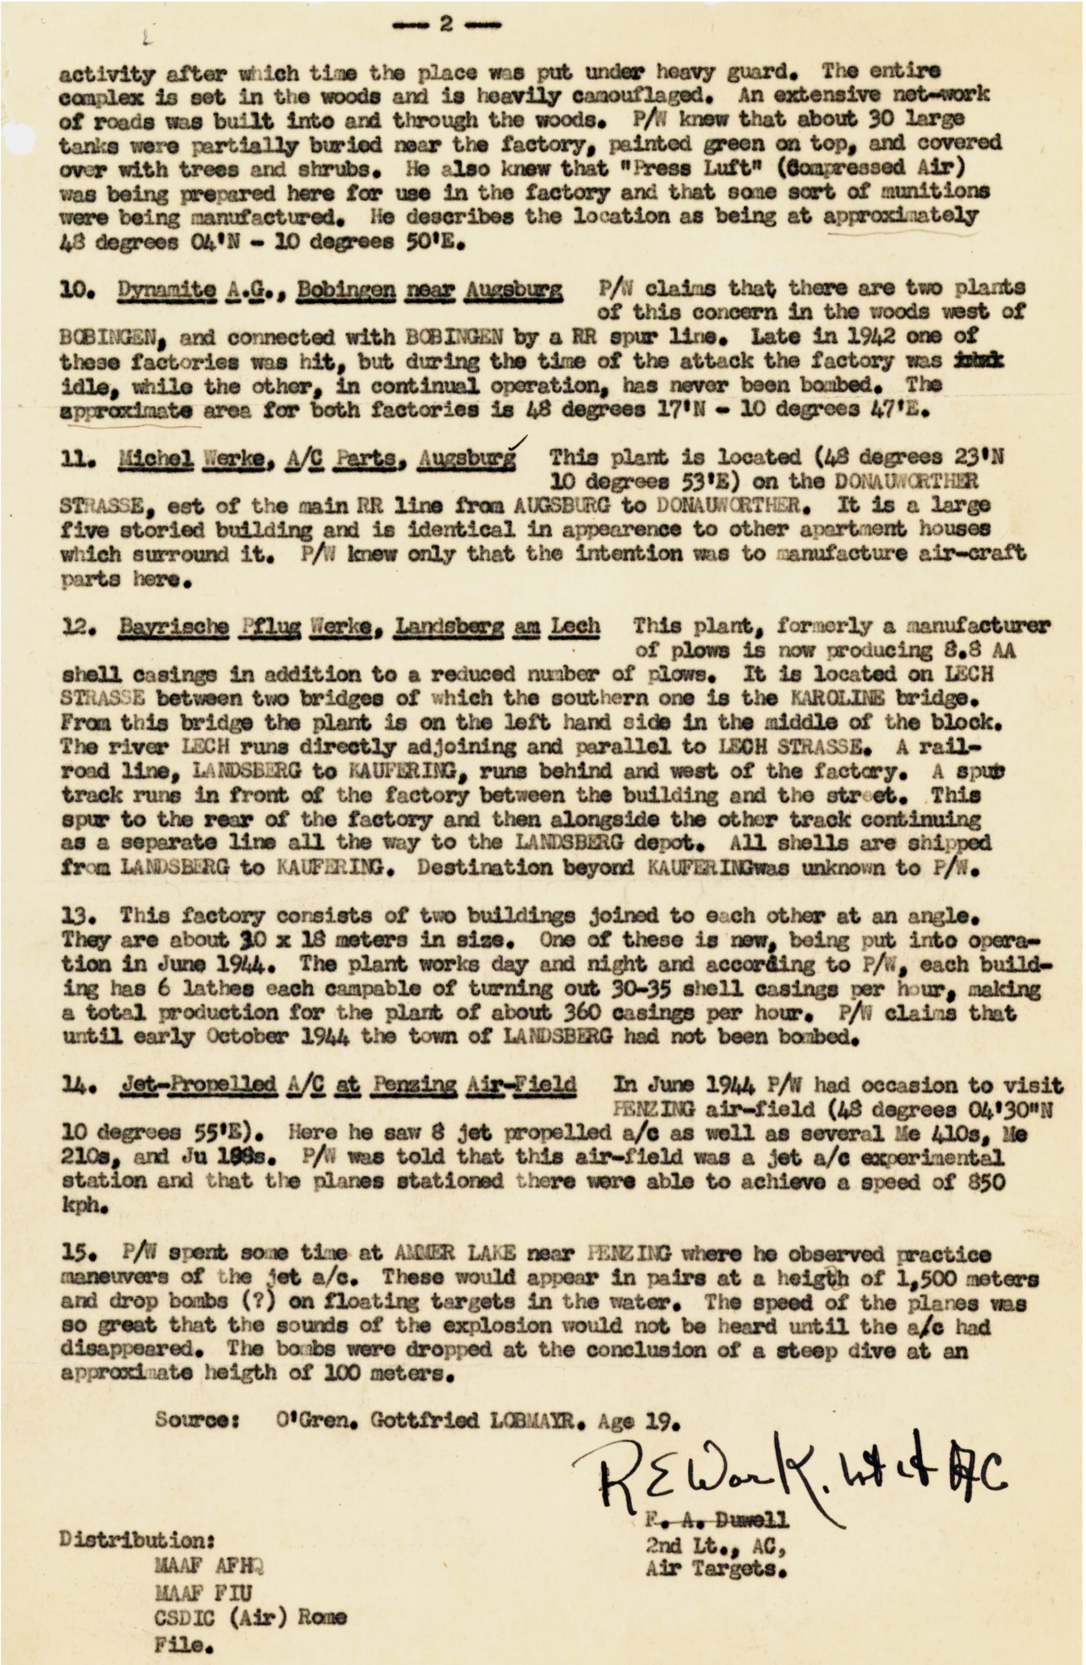
a.	47	degrees	53'20"N	— 10	degrees	56'E.	(West of ROTT)
b.	47	"	56' N	— 10	"	53'E.	(West of ISSING)
c.	47	"	59' N	— 10	"	53'30"E.	
d.	48	"	01'30"N	— 10	"	53'E.	

9. **Dynamite A.G. Kaufering at Landsberg** This plant was begun in 1939-40 and at that time curious civilians were informed that they need not be concerned as the project was of little importance. However, this did not quiet the suspicions that something highly secret was being performed, suspicions that are still rife today. In May 1943 there was a sudden increase in

Figure D.266: F. A. Duwell. 5th Army POW Cage (Air), Target Notes A/16. 7 November 1944. [AFHRA folder 512.619C-15A 1943–1945; AFHRA A5417 electronic pp. 966–967]

THIS PAGE DECLASSIFIED IAW EO 13526

AFHRA folder 512.619C-15A 1943-1945



— 2 —

activity after which time the place was put under heavy guard. The entire complex is set in the woods and is heavily camouflaged. An extensive net-work of roads was built into and through the woods. P/W knew that about 30 large tanks were partially buried near the factory, painted green on top, and covered over with trees and shrubs. He also knew that "Press Luft" (Compressed Air) was being prepared here for use in the factory and that some sort of munitions were being manufactured. He describes the location as being at approximately 48 degrees 04'N – 10 degrees 50'E.

10. Dynamite A.G., Bobingen near Augsburg P/W claims that there are two plants of this concern in the woods west of BOBINGEN, and connected with BOBINGEN by a RR spur line. Late in 1942 one of these factories was hit, but during the time of the attack the factory was idle, while the other, in continual operation, has never been bombed. The approximate area for both factories is 48 degrees 17'N – 10 degrees 47'E.

11. Michel Werke, A/C Parts, Augsburg This plant is located (48 degrees 23'N 10 degrees 53'E) on the DONAUWORTHER STRASSE, est of the main RR line from AUGSBURG to DONAUWORTHER. It is a large five storied building and is identical in appearence to other apartment houses which surround it. P/W knew only that the intention was to manufacture air-craft parts here.

12. Bayrische Pflug Werke, Landsberg am Lech This plant, formerly a manufacturer of plows is now producing 8.8 AA shell casings in addition to a reduced number of plows. It is located on LECH STRASSE between two bridges of which the southern one is the KAROLINE bridge. From this bridge the plant is on the left hand side in the middle of the block. The river LECH runs directly adjoining and parallel to LECH STRASSE. A railroad line, LANDSBERG to KAUFERING, runs behind and west of the factory. A spur track runs in front of the factory between the building and the street. This spur to the rear of the factory and then alongside the other track continuing as a separate line all the way to the LANDSBERG depot. All shells are shipped from LANDSBERG to KAUFERING. Destination beyond KAUFERINGwas unknown to P/W.

13. This factory consists of two buildings joined to each other at an angle. They are about 30 x 18 meters in size. One of these is new, being put into operation in June 1944. The plant works day and night and according to P/W, each building has 6 lathes each campable of turning out 30-35 shell casings per hour, making a total production for the plant of about 360 casings per hour. P/W claims that until early October 1944 the town of LANDSBERG had not been bombed.

14. Jet-Propelled A/C at Penzing Air-Field In June 1944 P/W had occasion to visit PENZING air-field (48 degrees 04'30"N 10 degrees 55'E). Here he saw 8 jet propelled a/c as well as several Me 410s, Me 210s, and Ju 188s. P/W was told that this air-field was a jet a/c experimental station and that the planes stationed there were able to achieve a speed of 850 kph.

15. P/W spent some time at AMMER LAKE near PENZING where he observed practice maneuvers of the jet a/c. These would appear in pairs at a heigth of 1,500 meters and drop bombs (?) on floating targets in the water. The speed of the planes was so great that the sounds of the explosion would not be heard until the a/c had disappeared. The bombs were dropped at the conclusion of a steep dive at an approximate heigth of 100 meters.

Very urgent INTELLIGENCE
Germany

Research on Secret Weapons

A center of research has been set up at KAPPEL, 37 km. north of Berlin, in a disguised woods. Near this center, and camouflaged by the same woods, there is the whole of E. M. de DOENITZ.

Researches are carried on vigorously upon the "atomic explosion", at the SS Technical Academy at ZELLENDORF (700 m. south of the (RR) station) and especially at BRNO in Bohemia. These experiments are pursued intensively by the old establishments of BAYER (the special section of the I. G. Farben near Berlin and in the vicinity of Regensburg).

[Apparently added later:]

see paragraphs 3 and 4 of cable 2877 December 21, 1944, from Bern IN—29784

MAR 20 1945

[It is very interesting that this report took on a renewed urgency for the U.S. on 20 March 1945, and that the information added then refers to a cable from Bern by U.S. spy Moe Berg; note that the actual date of that cable appears to be December 31, not December 21 [Petersen 2008, p. 625].]

Monthly Intelligence Summary. March 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

c. A report was received that a research center engaged in work on "atomic explosion" has been set up near Koralle, 37 kilometers north of Berlin. A study of air coverage of this area failed to reveal any visual evidence of TA activity.

[The correct name of this site appears to be Koralle as mentioned in the second document, not Kappel as mentioned in the first. (Perhaps the "p"s were "ρ"s, indicating a Slavic origin for this intelligence?) The German Naval High Command was located there during 1943–1945 (the first document mentioned Admiral Doenitz), and there may well have been other facilities in the same general area.]

CSDIC (AFHQ) A 315 (F.N. 721). 5 February 1944. HE 177—Germany's New Bomber Hope: Detailed interrogation report on He 177's shot down on January 23rd and 24th. [AFHRA A5417 electronic pp. 882, 886]

48. In many forest regions of Germany including one near REGENSBURG, the home of the P/W, the manufacture of the secret weapon or weapons is being rushed with utmost energy. Extreme security precautions are taken, such as keeping the workers in the factory, and not permitting them to go home.

Research Institutes

1. According to informant, eight research institutes whose purpose is the development of V-weapons, gases, bacteriological means of warfare, and atom smashing devices have existed or are functioning in Germany and Austria. Their locations are as follows:

   (a) Peenemünde (about 40 km northwest of Swinemünde)

   (b) Tegernsee (about 50 km south-southeast of Munich)

   (c) Schloss Hohenzollern at Sigmaringen

   (d) A stone quarry near Lebestan (sic—this may be Lehesten, about 50 km west of Plauen)

   (e) Tübingen. Nothing definite is known about this institute.

   (f) Floridsdorf, in the northeastern portion of Vienna. The institute is now closed, and its equipment is believed to have been moved to Tegernsee.

   (g) Freiburg-im-Breisgau. The institute is now closed, and its equipment is believed to have been moved to Sigmaringen.

   OSS Washington Comment: According to another informant, the Schloss Hohenzollern mentioned is located about 20 km south-southwest of Tübingen, not at Sigmaringen. This may be the missing eighth location.

Alcohol

2. A ball bearing factory in Hronow (about 130 km northeast of Prague) is adding alcohol to the gasoline for starting and landing rocket planes and for the new ramming plane (Rammflugzeug).

3. Alcohol is being distilled from wine for this purpose. It is expected that 2,000,000 liters will be obtained from the Schlumberger Co. of Vöslau (30 km south-southwest of Vienna).

Doc. No. 112, Subject: Waldow, Willi (27 September 1946). [NARA RG 319, Entry A1-134A, Box 17, Folder XE 169886, Russian Deportation of German Scientists and Technicians]

[...] Subject, while traveling between the Russian and American Zones on the 29th August 1946, made the acquaintance of a Mr. BRUECKNER in the railroad station STASSFURT (M52/D66). The conversation that took place consisted of BRUECKNER's description of his recent forced employment and subsequent escape from a Russian underground factory, located at SALZBERGWERKE (M52/D66) near STASSFURT. BRUECKNER, a German engineer, formerly engaged in atomic research as early as 1934 stated that a group of between two or three thousand Germans with scientific and technical backgrounds are being forcibly engaged at working on experiments dealing with atomic energy pertaining to development of the atomic bomb, as well as rocket experiments with the "V 2". The site of this factory is supposedly that of a former German underground factory used to manufacture special types of weapons during the war, located as SALZBERGWERKE. According to Subject BRUECKNER further stated that despite his previous knowledge of atomic energy, the work now being conducted is in an entirely new field.

INFORMATION ON POSSIBLE GERMAN WAR-TIME PRODUCTION
PLANT FOR URANIUM ISOTOPE 235, AND PRESENT
SOVIET INTEREST.

Section
Introduction.. I
Soviet Efforts to Secure Services of Source........................... II
Description of the Uranium Separation Installation.................... III
Direct Interrogation of Dipl. Ing. J. Greiner......................... IV
Evolution of Information.. V
Evaluation of Sources... VI

Section I

INTRODUCTION

1. The information in this report was obtained through Ing. Otto P. Fuchs, Austrian electrical engineer (See AIU/PIR/133, this office, dated 6 May 1947), who was placed under American "denial" contract through G-2, Headquarters, USFA, in March for an indefinite period, pending final decision in connection with "Project Paper-Clip". Fuchs had been interrogated by this office, and was preparing special technical reports on projects outlined in the above interrogation report (AIU/PIR/133), when the following information was revealed to him during trips to Vienna.

2. Although certain doubtful items are still being investigated, and the movements and work of Fuchs are being closely controlled by this office, it was felt that the information below might be sufficiently important to make a report on the facts available. Any further information obtained on this subject will be forwarded by this office to the agencies referred to in the distribution list below, unless instructions to the contrary are received from higher headquarters.

Section II

SOVIET EFFORTS TO SECURE SERVICES OF SOURCE.

3. Fuchs states that he visited Vienna in Mid-April 1947, to conduct business in connection with the reports he was preparing for this office. During his first visit he was contacted by an old acquaintance, a Dipl. Ing. Joseph Greiner, who operates an electrical laboratory at Vienna VI, Mariahilferstrasse 32. Greiner related to Fuchs that during the war he had developed an electrical apparatus by means of which special areas could be secured against trespassing. He had built such a device upon orders from the SS during the war, and as he was interested in assuring himself that the apparatus was correctly installed and properly operated, he had requested permission from the SS to visit the site where the apparatus was being used.

4. As Greiner was well-known to Adolf Hitler, according to Fuchs, and as the SS was aware of this, he was given immediate permission to visit the highly secret installation where his equipment had been set up. He claimed that during his tour of the premises he learned that the installation was engaged in the production of Uranium Isotope 235, through utilization of the power of natural lightning. By virtue of his technical knowledge he was able to note and interpret many of the details of this plant but was of the opinion that Fuchs was more capable than he of evaluating, calculating and determining the exact nature of the work so that the project could be judged by competent scientists.

SECRET

5. Greiner then explained that the real purpose of his meeting with Fuchs was to enlist him for the Soviets to undertake such an evaluation, as the Soviets had expressed great interest in the project on the strength of Greiner's account. This evaluation was to be based upon the story that Greiner was able to relate. It was to consist of drawings, calculations, and conclusions as to the exact nature of the installation. Fuchs was to conclude from this whether or not the described method was a practical one for the separation of Uranium Isotope 235, and whether it appeared of sufficient value to warrant further Russian exploitation.

6. Although Fuchs had no interest in preparing such data for the Soviets, because of his contract with the Americans, he felt that if he turned the offer down too bluntly, he might appear in a somewhat suspicious light. Neither Greiner nor the Russians were apparently aware at the time that Fuchs was under temporary contract to the United States. When Fuchs indicated that he would appreciate more definite information before he committed himself, Greiner suggested that a thorough discussion be held on the next day. Fuchs immediately went to Technical Intelligence, G-2, Headquarters, USFA, through which office he had been placed under contract, and explained what Greiner had told him. It was suggested to him that he make every effort to have Greiner present his information to the Americans, and failing in this, to at least continue the discussions until he (Fuchs) had sufficient information to reconstruct the project, which he should then present to the Americans.

7. As arranged, Fuchs met Greiner the next day and casually suggested to him that he should offer his information to the Americans, whereupon Greiner was emphatic in his opposition to such a step, explaining that the Americans were only interested in obtaining information either for nothing or for the lowest possible reimbursement, whereas the Soviets paid well and promptly. Greiner then suggested that he and Fuchs go immediately to the Soviet headquarters and discuss the matter with Dr. Garin. (Dr. Garin has come to the attention of this office in several instances as the Vienna Soviet technical intelligence contact man. He sometimes calls himself Major or Dr. Garin and sometimes Dr. Samsonoff).

8. Fuchs was cordially received by Garin who immediately told him that he was no doubt the individual who could best reconstruct the workings of the Uranium Isotope 235 production plant. Financial arrangements were promptly suggested, and Fuchs claims that he was to be paid the exorbitant sum of two hundred thousand (200,000) Shillings for the complete reconstruction and mathematical calculation of the project, which plans Fuchs estimated could be completed in two to three months. Fuchs was also informed that he should return to Garin's office next day with a two or three page outline of how he intended to develop his plans on the project, whereupon contracts would be ready for signature. Fuchs was to get a down payment of two thousand (2,000) Shillings for the outline after he had signed the contract.

9. Upon completion of the conversation, Fuchs returned to Technical Intelligence, G-2, Hq, USFA, and reported what had taken place. It was arranged that he leave Vienna at once, proceed to the Air Section Interrogation Unit at Gmunden, in the US Zone of Austria, and submit all information he had obtained. After having informed Greiner that personal matters necessitated his immediate return to his home, Fuchs left Vienna that evening. As Fuchs had not as yet obtained sufficient data from Greiner to complete his own interpretation of the Uranium undertaking, he returned to Vienna several days later. He told Greiner that he was in Vienna again on other business, on a hurried, one-day stay, and would appreciate further explanations and descriptions so that he could begin a preliminary evaluation of the project upon his return to his home in Kitzbuehel. He claims that he questioned Greiner very carefully and thoroughly and from his answers obtained sufficient data to reconstruct the project in general terms. He then went to a Frau Dr. G. Urm, a former scientific co-worker, with whom he spent two days completing his conclusions from the information Greiner had given him. When this paper was completed, Fuchs reported to the Air Interrogation Unit, at Gmunden, and turned over all information as well as a report with drawings which reproduced the alleged German installation as well as Fuchs and Dr. Urm were able to develop it from the available data.

- 2 -
SECRET

10. Fuchs was advised by the Air Interrogation Unit, this office, to inform Dr. Garin and Greiner that he had accepted other employment and that he would be unable to undertake the project outlined in his discussion with Garin in Vienna. He was also told to phrase his letter in such a way that it might be possible for him to take up relations with Dr. Garin regarding the matter at a later date. In complying with these instructions, Fuchs wrote to Greiner, requesting that he inform Garin of his other obligations. (See copy of the letter Incl #1).

Section III

DESCRIPTION OF THE URANIUM SEPARATION INSTALLATION

11. The following information is taken from Fuchs' report (Incl.#2), from the accompanying drawings reproduced to half their original size (Incls # 3 & 4), and from other data obtained by Fuchs in subsequent discussions with Greiner. (It should be noted that some of the information appearing in Fuchs' attached report differs from information appearing elsewhere in this report. This is due to the fact that conversations Fuchs held with Greiner, after the report was written, clarified certain aspects of the Uranium project and also developed new information).

12. The German unit which was responsible during the war for this undertaking is claimed by Greiner to have been "The Highest SS and Police Direction of the Ukraine" ("Der Hoechste SS und Polizeifuehrer der Ukraine"). The project operated under the code-name "Unternehmen Buntspecht" and was carried out by specialists who were exclusively SS members. Various research problems were dealt with but special emphasis was placed upon the production of Uranium Isotope 235. The work was under the direction of SS officers Dr. Boehm, Dr. Beck and Dr. Bachman. Greiner claims that Boehm and Beck are now residing in Argentina and that Bachman is still in Germany or Austria (See paragraphs 14 and 27 below for additional information on Bachman).

13. Possible confirmation of Greiner's claim as to the present location of at least Dr. Beck, came to this office through another source. Attention was called to an item in a Vienna Communist weekly, "Stimme der Frau", dated 24 May 1947, in which the Paris (Communist) paper "Ce Soir" is paraphrased as follows:

> "We note that the Paris Paper "Ce Soir" in a detailed article, points to the fact that in an atomic research laboratory of the fascist country Argentina, research is now being carried on under the direction of two specialists who, some time ago, were in the service of the Nazi war machine. The two men involved are the German Dr. Richard Gans and the Austrian Dr. Guido Beck. This work is not being financed by official state funds, but largely out of "Black Funds" of private fortunes estimated at roundly a billion dollars which were safely smuggled out of Germany just in time".

14. Fuchs states that he pressed Greiner considerably for information on the present whereabouts of Bachman. He claims that Greiner told the following story regarding Bachman's present location: Greiner related that toward the end of May, after Fuch's original contact with him regarding this Uranium installation, Dr. Bachman called upon Greiner in Vienna to pay what Greiner describes as a social call. Greiner stated that Bachman had heard of Greiner's book "The End of The Hitler Myth" ("Das Ende des Hitler Mythos"), and that he was calling to ask if he might have an autographed copy. Greiner complied with this request and immediately asked Bachman about the fate of the Uranium installation. Greiner told Fuchs that Bachman was very non-committal and practically refused to speak about the Uranium installation. Greiner told Fuchs that Bachman claimed he was in the services of the Americans and that he appeared at Greiner's office dressed in an American army uniform. Greiner claimed that to his question as to how a former SS scientist now came to wear an American uniform, Bachman is said to have answered something to the effect that "in these times things change quickly". Greiner insisted to Fuchs that Bachman wore US insignia buttons on either side of his collar. (This is the story that Fuchs claims to have had from Greiner concerning Bachman. See paragraph 27 for contradicting story that Greiner gave to interrogators of this office on Bachman.)

- 3 -
SECRET

15. Greiner described the location of the installation to Fuchs as follows: From Woerth an der Isar, located a short distance NE of Landshut, Germany, a 4 to 5 hour automobile ride over very poor roads in a mountainous area, took Greiner to the site of the installation which was located about 1,500 meters above sea level. Greiner claims that the trip was made at night, that he had no knowledge as to the direction taken from Woerth, that he recalls no towns passed through during the five hour ride, and that he obtained no hint as to where he was during the day he spent at the installation. He emphatically claims that he does not know whether the installation was located in the Bavarian Alps, South of Woerth, or in the mountainous area on the German-Czechoslovakian border, East of Woerth.

16. Greiner claims that the installation was scheduled for dismantling and destruction of permanent buildings in December 1944 - January 1945 and was to be evacuated to another destination. He claims that his electrical alarm system was installed in November 1944 to protect the area against trespassers who might be drawn to the site through curiosity over the heightened activity that would naturally accompany the evacuation. (See Incl #5 for photostatic copy of the order blank which Greiner told Fuchs was for the alarm system used at the Uranium installation). During the conversation Greiner claims to have had with Bachman regarding the closing of the installation, Bachman is said to have mentioned that it was his personal opinion that the installation was scheduled to move to Spain, although nothing had been made officially known in this regard. It is Greiner's opinion that the installation might have moved to Spain and then on to Argentina.

17. Greiner's observations on the site prior to its destruction in December 1944, and the report of these observations to Fuchs, enabled Fuchs and Urm to prepare the two drawings (Incls # 3 and 4), together with the explanatory report (Incl #2). These theoretically represent their impressions of how the installation and the Isotope producing apparatus probably looked and operated.

18. Drawing #1 (Incl #3), is Fuchs' impression of the individual apparatus for the separation of Uranium Isotope 235. There were twenty of these units. They could be described approximately as follows:

19. Inside the circular containers (No. 10) was a round glass body (No. 1), which had a diameter of approximately 500 milimeters and a height of approximately 2,000 milimeters. This body appeared to be made out of poured glass (Gussglas) and had a wall thickness of 50 milimeters. In the center of this body was placed a copper bar (No. 7) which was attached inside the body to a cathode of pure metallic Uranium in plate form (No. 2). Underneath this plate a circular supplementary electrode (No. 3) was attached to the glass wall (No. 1). This electrode was apparently made of graphite. According to a remark of Dr. Boehm, the Uranium Isotope 235 was attracted to this graphite plate (No. 3) through magnetic action, the heavier components of Uranium lining the bottom of the plate and other, lighter components attaching themselves higher and higher on the plate depending upon their specific weights. This plate (No. 3) was connected by means of a copper rod to another, smaller glass body (No. 6), in which 2 electrodes were visible. The lower electrode was connected with the ground by a copper tube through an insulator (No. 12). On the bottom of the glass body (No. 1), it appeared as if a pipe-line went through the floor and probably connected with the vacuum pumping installation underneath. These two tubes, which were probably gas-discharge outlets, were

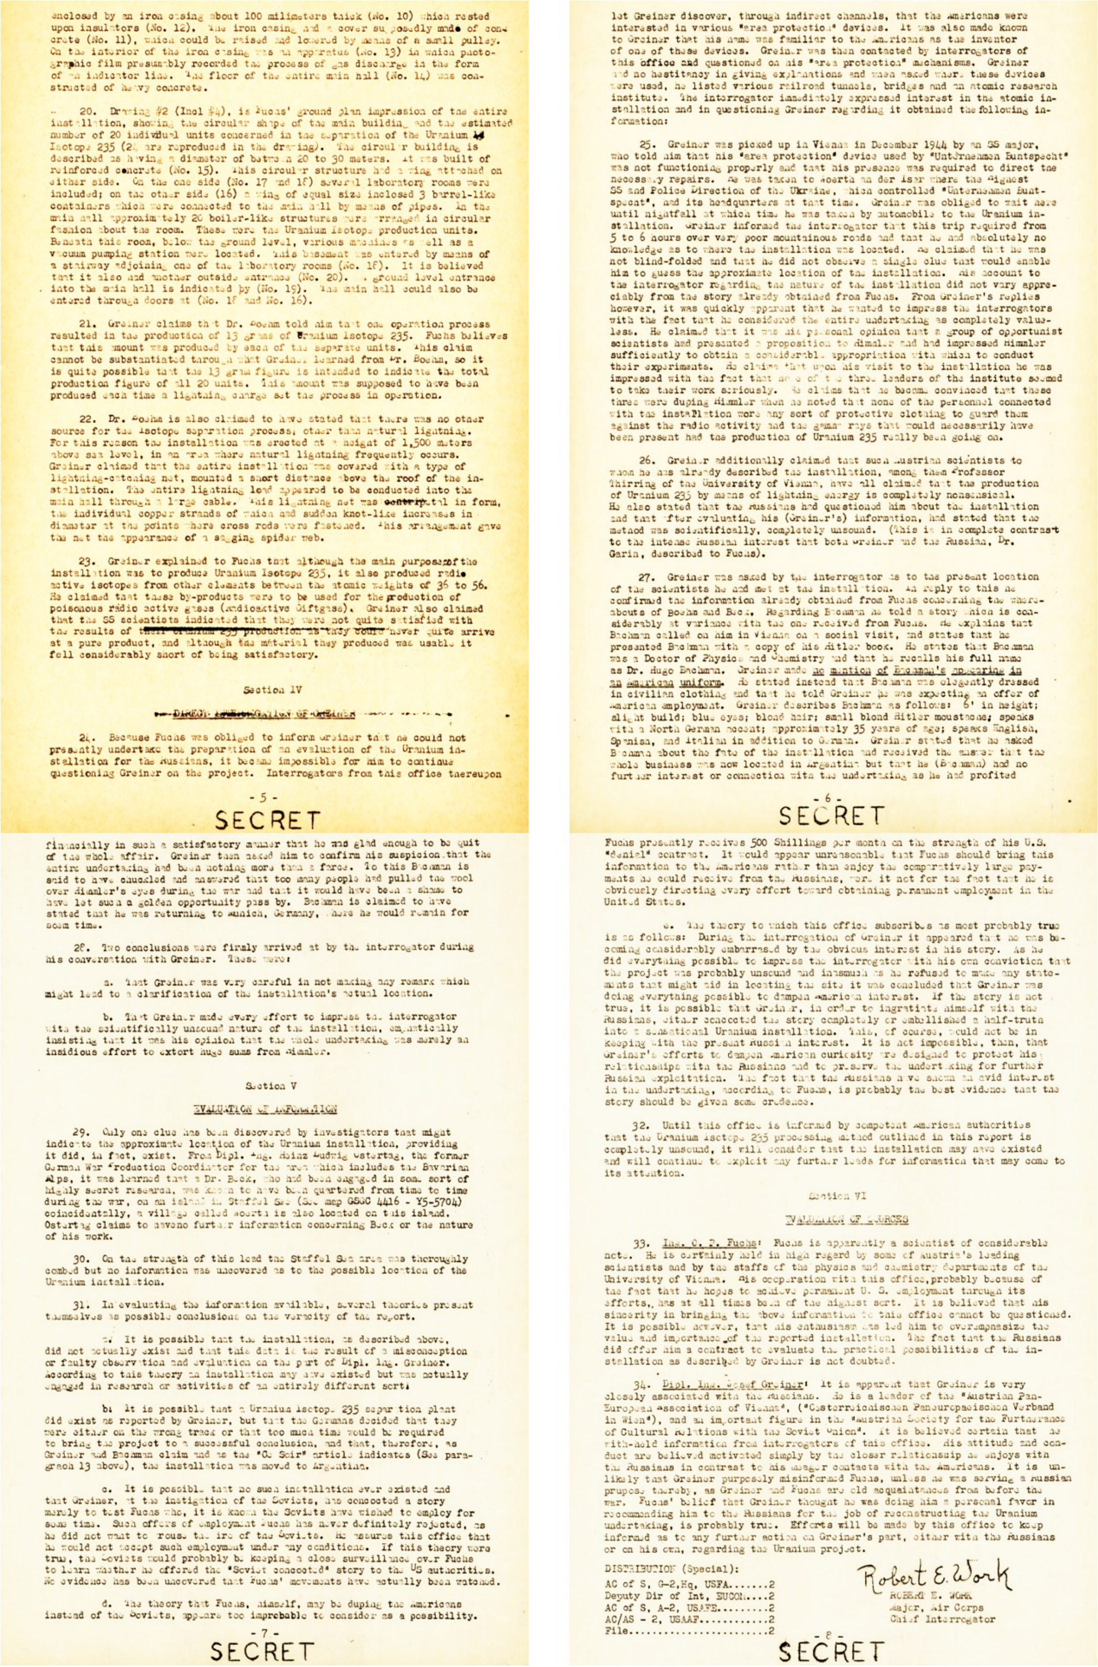
SECRET

Figure D.270: Robert E. Work. 21 July 1947. Information on Possible German War-Time Production Plant for Uranium Isotope 235, and Present Soviet Interest. [AFHRA folder 506.619B 1945–47; AFHRA A5183 frames 0497–0504] Postwar interrogations mentioned a wartime electromagnetic uranium enrichment plant at an unspecified site in the Bavarian Alps.

THIS PAGE DECLASSIFIED IAW EO 13526



enclosed by an iron casing about 100 milimeters thick (No. 10) which rested upon insulators (No. 12). The iron casing and a cover supposedly made of concrete (No. 11), which could be raised and lowered by means of a small pulley. On the interior of the iron casing was an apparatus (No. 13) in which photographic film presumably recorded the process of gas discharge in the form of an indicator line. The floor of the entire main hall (No. 14) was constructed of heavy concrete.

20. Drawing #2 (Incl #4), is Fuchs' ground plan impression of the entire installation, showing the circular shape of the main building and the estimated number of 20 individual units concerned in the separation of the Uranium Isotope 235 (2[illegible] are reproduced in the drawing). The circular building is described as having a diameter of between 20 to 30 meters. It was built of reinforced concrete (No. 15). This circular structure had a wing attached on either side. On the one side (No. 17 and 18) several laboratory rooms were included; on the other side (16) a wing of equal size inclosed 3 barrel-like containers which were connected to the main hall by means of pipes. In the main hall approximately 20 boiler-like structures were arranged in circular fashion about the room. These were the Uranium Isotope production units. Beneath this room, below the ground level, various machines as well as a vacuum pumping station were located. This basement was entered by means of a stairway adjoining one of the laboratory rooms (No. 18). It is believed that it also had another outside entrance (No. 20). A ground level entrance into the main hall is indicated by (No. 19). The main hall could also be entered through doors at (No. 18 and No. 16).

21. Greiner claims that Dr. Boehm told him that one operation process resulted in the production of 13 grams of Uranium Isotope 235. Fuchs believes that this amount was produced by each of the separate units. This claim cannot be substantiated through what Greiner learned from Dr. Boehm, so it is quite possible that the 13 gram figure is intended to indicate the total production figure of all 20 units. This amount was supposed to have been produced each time a lightning charge set the process in operation.

22. Dr. Boehm is also claimed to have stated that there was no other source for the Isotope separation process, other than natural lightning. For this reason the installation was erected at a height of 1,500 meters above sea level, in an area where natural lightning frequently occurs. Greiner claimed that the entire installation was covered with a type of lightning-catching net, mounted a short distance above the roof of the installation. The entire lightning load appeared to be conducted into the main hall through a large cable. This lightning net was centripetal in form, the individual copper strands of which had sudden knot-like increases in diameter at the points where cross rods were fastened. This arrangement gave the net the appearance of a sagging spider web.

23. Greiner explained to Fuchs that although the main purpose of the installation was to produce Uranium Isotope 235, it also produced radio active isotopes from other elements between the atomic weights of 36 to 56. He claimed that these by-products were to be used for the production of poisonous radio active gases (Radioaktive Giftgase). Greiner also claimed that the SS scientists indicated that they were not quite satisfied with the results of ~~their Uranium 235 production as they could~~ never quite arrive at a pure product, and although the material they produced was usable it fell considerably short of being satisfactory.

Section IV

DIRECT INTERROGATION OF GREINER

24. Because Fuchs was obliged to inform Greiner that he could not presently undertake the preparation of an evaluation of the Uranium installation for the Russians, it became impossible for him to continue questioning Greiner on the project. Interrogators from this office thereupon

- 5 -

SECRET

let Greiner discover, through indirect channels, that the Americans were interested in various "area protection" devices. It was also made known to Greiner that his name was familiar to the Americans as the inventor of one of these devices. Greiner was then contacted by interrogators of this office and questioned on his "area protection" mechanisms. Greiner had no hesitancy in giving explanations and when asked where these devices were used, he listed various railroad tunnels, bridges and an atomic research institute. The interrogator immediately expressed interest in the atomic installation and in questioning Greiner regarding it obtained the following information:

25. Greiner was picked up in Vienna in December 1944 by an SS major, who told him that his "area protection" device used by "Unternehmen Buntspecht" was not functioning properly and that his presence was required to direct the necessary repairs. He was taken to Woerth an der Isar where the Highest SS and Police Direction of the Ukraine, which controlled "Unternehmen Buntspecht", had its headquarters at that time. Greiner was obliged to wait here until nightfall at which time he was taken by automobile to the Uranium installation. Greiner informed the interrogator that this trip required from 5 to 6 hours over very poor mountainous roads and that he had absolutely no knowledge as to where the installation was located. He claimed that he was not blind-folded and that he did not observe a single clue that would enable him to guess the approximate location of the installation. His account to the interrogator regarding the nature of the installation did not vary appreciably from the story already obtained from Fuchs. From Greiner's replies however, it was quickly apparent that he wanted to impress the interrogators with the fact that he considered the entire undertaking as completely valueless. He claimed that it was his personal opinion that a group of opportunist scientists had presented a proposition to Himmler and had impressed Himmler sufficiently to obtain a considerable appropriation with which to conduct their experiments. He claims that upon his visit to the installation he was impressed with the fact that none of the three leaders of the institute seemed to take their work seriously. He claims that he became convinced that these three were duping Himmler when he noted that none of the personnel connected with the installation wore any sort of protective clothing to guard them against the radio activity and the gamma rays that would necessarily have been present had the production of Uranium 235 really been going on.

26. Greiner additionally claimed that such Austrian scientists to whom he has already described the installation, among them Professor Thirring of the University of Vienna, have all claimed that the production of Uranium 235 by means of lightning energy is completely nonsensical. He also stated that the Russians had questioned him about the installation and that after evaluating his (Greiner's) information, had stated that the method was scientifically, completely unsound. (This is in complete contrast to the intense Russian interest that both Greiner and the Russian, Dr. Garin, described to Fuchs).

27. Greiner was asked by the interrogator as to the present location of the scientists he had met at the installation. In reply to this he confirmed the information already obtained from Fuchs concerning the whereabouts of Boehm and Beck. Regarding Bachman he told a story which is considerably at variance with the one received from Fuchs. He explains that Bachman called on him in Vienna on a social visit, and states that he presented Bachman with a copy of his Hitler book. He states that Bachman was a Doctor of Physics and Chemistry and that he recalls his full name as Dr. Hugo Bachman. Greiner made no mention of Bachman's appearing in an American uniform. He stated instead that Bachman was elegantly dressed in civilian clothing and that he told Greiner he was expecting an offer of American employment. Greiner describes Bachman as follows: 6' in height; slight build; blue eyes; blond hair; small blond Hitler moustache; speaks with a North German accent; approximately 35 years of age; speaks English, Spanish, and Italian in addition to German. Greiner stated that he asked Bachman about the fate of the installation and received the answer that the whole business was now located in Argentina but that he (Bachman) had no further interest or connection with the undertaking as he had profited

- 6 -

SECRET

financially in such a satisfactory manner that he was glad enough to be quit of the whole affair. Greiner then asked him to confirm his suspicion that the entire undertaking had been nothing more than a farce. To this Bachman is said to have chuckled and answered that too many people had pulled the wool over Himmler's eyes during the war and that it would have been a shame to have let such a golden opportunity pass by. Bachman is claimed to have stated that he was returning to Munich, Germany, where he would remain for some time.

28. Two conclusions were firmly arrived at by the interrogator during his conversation with Greiner. These were:

a. That Greiner was very careful in not making any remark which might lead to a clarification of the installation's actual location.

b. That Greiner made every effort to impress the interrogator with the scientifically unsound nature of the installation, emphatically insisting that it was his opinion that the whole undertaking was merely an insidious effort to extort huge sums from Himmler.

Section V

EVALUATION OF INFORMATION

29. Only one clue has been discovered by investigators that might indicate the approximate location of the Uranium installation, providing it did, in fact, exist. From Dipl. Ing. Heinz Ludwig Ostertag, the former German War Production Coordinator for the area which includes the Bavarian Alps, it was learned that a Dr. Beck, who had been engaged in some sort of highly secret research, was known to have been quartered from time to time during the war, on an island in Staffel See (See map GSGC 4416 - Y5-5704) coincidentally, a village called Woerth is also located on this island. Ostertag claims to haveno further information concerning Beck or the nature of his work.

30. On the strength of this lead the Staffel See area was thoroughly combed but no information was uncovered as to the possible location of the Uranium installation.

31. In evaluating the information available, several theories present themselves as possible conclusions on the veracity of the report.

a. It is possible that the installation, as described above, did not actually exist and that this data is the result of a misconception or faulty observation and evaluation on the part of Dipl. Ing. Greiner. According to this theory an installation may have existed but was actually engaged in research or activities of an entirely different sort.

b. It is possible that a Uranium Isotope 235 separation plant did exist as reported by Greiner, but that the Germans decided that they were either on the wrong track or that too much time would be required to bring the project to a successful conclusion, and that, therefore, as Greiner and Bachman claim and as the "Ce Soir" article indicates (See paragraph 13 above), the installation was moved to Argentina.

c. It is possible that no such installation ever existed and that Greiner, at the instigation of the Soviets, has concocted a story merely to test Fuchs who, it is known the Soviets have wished to employ for some time. Such offers of employment Fuchs has never definitely rejected, as he did not want to arouse the ire of the Soviets. He assures this office that he would not accept such employment under any conditions. If this theory were true, the Soviets would probably be keeping a close surveillance over Fuchs to learn whether he offered the "Soviet concocted" story to the US authorities. No evidence has been uncovered that Fuchs' movements have actually been watched.

d. The theory that Fuchs, himself, may be duping the Americans instead of the Soviets, appears too improbable to consider as a possibility.

- 7 -

SECRET

Fuchs presently receives 500 Shillings per month on the strength of his U.S. "denial" contract. It would appear unreasonable that Fuchs should bring this information to the Americans rather than enjoy the comparatively large payments he could receive from the Russians, were it not for the fact that he is obviously directing every effort toward obtaining permanent employment in the United States.

e. The theory to which this office subscribes as most probably true is as follows: During the interrogation of Greiner it appeared that he was becoming considerably embarrassed by the obvious interest in his story. As he did everything possible to impress the interrogator with his own conviction that the project was probably unsound and inasmuch as he refused to make any statements that might aid in locating the site it was concluded that Greiner was doing everything possible to dampen American interest. If the story is not true, it is possible that Greiner, in order to ingratiate himself with the Russians, either concocted the story completely or embellished a half-truth into a sensational Uranium installation. This, of course, would not be in keeping with the present Russian interest. It is not impossible, then, that Greiner's efforts to dampen American curiosity are designed to protect his relationships with the Russians and to preserve the undertaking for further Russian exploitation. The fact that the Russians have shown an avid interest in the undertaking, according to Fuchs, is probably the best evidence that the story should be given some credence.

32. Until this office is informed by competent American authorities that the Uranium Isotope 235 processing method outlined in this report is completely unsound, it will consider that the installation may have existed and will continue to exploit any further leads for information that may come to its attention.

Section VI

EVALUATION OF SOURCES

33. Ing. C. P. Fuchs: Fuchs is apparently a scientist of considerable note. He is certainly held in high regard by some of Austria's leading scientists and by the staffs of the physics and chemistry departments of the University of Vienna. His cooperation with this office, probably because of the fact that he hopes to achieve permanent U. S. employment through its efforts, has at all times been of the highest sort. It is believed that his sincerity in bringing the above information to this office cannot be questioned. It is possible however, that his enthusiasm has led him to overemphasize the value and importance of the reported installation. The fact that the Russians did offer him a contract to evaluate the practical possibilities of the installation as described by Greiner is not doubted.

34. Dipl. Ing. Josef Greiner: It is apparent that Greiner is very closely associated with the Russians. He is a leader of the "Austrian Pan-European Association of Vienna", ("Oesterreichischen Paneuropaeischen Verband in Wien"), and an important figure in the "Austrian Society for the Furtherance of Cultural Relations with the Soviet Union". It is believed certain that he with-held information from interrogators of this office. His attitude and conduct are believed motivated simply by the closer relationship he enjoys with the Russians in contrast to his meager contacts with the Americans. It is unlikely that Greiner purposely misinformed Fuchs, unless he was serving a Russian purpose thereby, as Greiner and Fuchs are old acquaintances from before the war. Fuchs' belief that Greiner thought he was doing him a personal favor in recommending him to the Russians for the job of reconstructing the Uranium undertaking, is probably true. Efforts will be made by this office to keep informed as to any further action on Greiner's part, either with the Russians or on his own, regarding the Uranium project.

SECRET

Special Report #25 Captured Personnel and Material Branch 9 Sept. 1944.
M.S.H. / W.O. H.

Estimate of Veracity: Previous information obtained from this source has proven to be reliable.

Subject: REICHSPOST CENTRALE.

Source was employed as an architect and draughtsman at the Reichspost Centrale, Karlsruhe from Oct. 1940 until Jan. 1942. Everything connected with mail, telephone, telegraph, and radio came under the jurisdiction of the Reichspost Centrale. In addition, the Reichspost supported a research department known as the Forschungs Institute der Deutscher Reichspost. This department also financed individuals in research work of value to the Reich.

Source and one other, Helmut Hentz, drew up the plans for remodeling of damaged post office buildings or for new constructions. Hentz was at one time given the task of planning the remodeling of a double house in Heidelberg which at one time had belonged to Dr. Bergius, well known for his many "ersatz" articles.

A certain professor of physics at Heidelberg University desired to purchase the home of Dr. Bergius who at that time was in need of extra funds. The professor was engaged in experiments in photography and needed a laboratory to continue the work. Dr. Bergius asked far more than the house was worth, according to this source, but the Reichspost Minister advanced the required amount and supported the professor in his research. According to source, this research was concerned with the effect temperature changes had on photographs. According to source, Hentz said that, in conversations, the professor had told him that the English were also working on this same problem and that it was believed possible, through the change in colors of several photos taken at intervals in the night, to determine whether a ship might be passing through the Channel.

The remodeling of this house was not begun while source worked for the Reichspost but while he was home on furlough in Nov. 1942, he learned that it was then in progress.

During this period of employment, he also drew plans for a large, new, post office at Karlsruhe, EMMINDINGEN near FREIBURG, WALDSHUT, BADEN BADEN, and LAHR. He also planned repairs at SULZ and many small places in Elsass.

At Karlsruhe:

President der Reichspost Direktion Karlsruhe: KOEHL
Oberpostbaurat LUEDORFF.

According to source, Luedorff was a very intelligent and capable man. He was an outspoken Anti-Nazi and apparently only his value to the Reichspost kept him from being arrested. Luedorff was the final word on construction in this area and later was sent to FRANKFORT AM MAIN. He was last known to be in the HANNOVER Area.

Special Report #25 (Cont'd) 9 Sept. 1944.

Also located at Karlsruhe and connected with the Technische Hochschule, is the Chemical Institute. Source worked directly opposite the entrance to the Institute and on several occasions saw a General of the Luftwaffe, accompanied by other high ranking officers enter the Institute. They were in the company of Rudolf Weigel, the director of the Chemical Institute. Weigel was a former student there and had studied "licht technique". He became and assistant professor there and, through intrigue, ousted the former director and took over the job. He is 150% Nazi.

In trying to recall all new plans he had made or new buildings constructed, source disclosed that many garages for busses had been built in the Schwarzwald. Providing transportation also seemed to be the duty of the Reichspost in this area.

In this connection, the writer of this report wishes to add that he himself, while living in Germany from Nov. 1937 until Sept. 1941, heard many rumors of underground construction in the Schwarzwald. Bus loads of soldiers were taken into these projects at night with the added precaution of darkened windows on the busses, so that the soldiers could see nothing. They were not told where they were other than in the Schwarzwald. They remained 24 hours and went out again at dark. The nature of the construction was not disclosed.

Location of Dr. Bergius House: Source had never seen this house and could not pin point it on an aerial photo of Heidelberg. He knows it is located near Philosophenweg, above and to the left of the Karl Theodore Bridge which is the first bridge below the dam. See aerial phot #4010-11 D 558 541 S.O. 14-5-43 F/20.

I. LIPPOLDSBERG - V-WEAPON PLANT:

In December 1943, at Christmas time, P/W was at home on leave in Hanover. During this time he met an old friend of his, Dr. Franz Erhardt, husband of P/W's cousin. This man told him that he was now working in a small but highly important war industry in Lippoldsberg on the Weser, not far from Cassel. P/W's informant had been employed there for the last seven months (he formerly was a technician for Siemens and Schuckert in Berlin and is the holder of 16 patents which P/W believes are inventions in the optical field inasmuch as the Dr. mentioned briefly that he was engaged in "Fernsehapparat (television) Arbeit" while still with Siemens and Schuckert.)

P/W himself was in the vicinity of Lippoldsberg in 1939 in the company of a friend who owned a number of trucks engaged in construction of a new State owned factory and had occasion, one day, to ride out to the factory site with his friend. When he questioned Dr. Erhardt it developed that the place where the latter was now working was the same as P/W himself had seen under construction in 1939. Even at that time there was considerable secrecy about the place and it was generally rumored to be a munitions plant. The factory area contained at that time about 25 structures, some of them already finished, but most of them still under construction. Some of the buildings looked to P/W like regular concrete bunkers, but the rest of them were more or less conventional type brick buildings with thick walls and large windows. The roofs of the completed buildings had already been camouflaged with plantings of evergreen trees and grass to harmonize with the surrounding terrain. A maze of pipes and conduits linked the buildings.

By drawing out the conversation P/W managed to get his informant to talk a little more about the plant. The Dr. finally admitted to P/W that they were doing highly secret and important work on "Vergeltungs Waffen" (retribution weapons) and P/W, although not a technician himself and hence unable to pursue the subject further even if the Dr. had been willing to talk about it freely, feels that either V-1 or V-2 was meant. In view of the small number of workers (not more than 250 to 300) it is possible that this plant may be used for experimental work or component part manufacture rather than finished projectiles. It is interesting also to note that all of the workers are Germans of "tested loyalty."

P/W has pinpointed location of the plant as follows: Map Reference is USLAR 1:25,000, Sheet 4323, E27°13'8" - N 51°37'20". This is just SW of the little town of Lippoldsberg below the apez of a triangle formed by the intersection of two country roads. The factory area itself may by now be much larger than it was when P/W saw it, as his conversion with Dr. Erhardt leads him to believe its facilities have been extended.

MEMORANDUM to THE OFFICER IN CHARGE

Subject: Power Facilties in Germany.

During the course of an interview on other matters, Mr. Erro O. Erkko of Hercules Corporation, Wilmington, Delaware, on 10 July 1944 advised this Agent that, in his opinion, the location of power plants and storage facilities in coal and salt mines in the Ruhr Valley of Germany should be investigated for possible affiliation with a German DSM project. Erkko stated that in 1938, he understood the Germans were building extensive power plants underground in abandoned and sometimes operatible coal and salt mines in the Ruhr Valley. He stated that his personal information did not extend further than that stated. However, he gave the name of Dr. Hans Lebach, presently employed by Habeg Corporation, Wilmington, Delaware, as possessing further information concerning these power plants. Habeg reputedly came to this country in 1940 or 1941 as a refugee and had in his possession at that time photographs and diagrams of the underground power plants of Germany. Erkko stated that he had previously reported this information to Major Cavanaugh of the Army Air Forces, but does not know whether or not it was followed up.

/s/ Bernard W. Menke,
Special Agenc, CIC.

SUBJECT: Hydro-Electric plants over 50 MW capacity in Germany and Austria that might have been started up in the last 6 months

TO : Lt Col William P. Maddox
OSS
72 Grosvenor Street

1. There is enclosed a list of hydro-electric stations over 50 MW capacity in Germany and Austria which may have been started up in the last 6 months.

2. It is requested that a check of your files be made of the general area surrounding each of these plants for intelligence reports of secret factories, underground plants and analogous reports. Particular attention should be afforded to those areas where plants are located and the disposal of the energy produced is not known for certain, and to the large new plant at Braunau which is reported to be a new aluminum works. Like attention should be given the general area of the power station on the Aache River, which is reported to have been built for a secret purpose.

3. A copy of this letter is being sent to Lt Commander Welch and it is requested that a similar search be made of files available to his office.

NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2
GERMANY: US Wartime Positive Int. (July-October 1944)

Hydro-electric stations over 50 MW capacity in Germany and Austria which may have been started up in last six months.

1. WITZNAU (Germany)
(SCHLUCHSEE HYDRO Scheme). Capacity 176 MW. This is a peak-load pumped-storage station used for general grid supply. It was completed certainly not earlier than the end of 1942 and may have been completed in the last 6 months.

2. HOHENWARTE (Germany)
(SAALE HYDRO Scheme). Capacity 50 MW. This is a peak load pumped-storage station used for general grid supply. It was partly built before the war but completion was deferred for a time. It is believed that it has since been completed - possibly in the last 6 months.

3. PIRKSCHMIED (Austria)
(DRAU HYDRO Scheme). Capacity 50 MW. This is a low-head flow station producing about 220 million kWh p.a. The disposal of the energy produced is not known for certain but it is believed that part is supplied to a new local industrial area and the remainder supplied to the grid. The station was completed in 1943 - possibly in the last 6 months.

4. OBERVERMUNT
RODUND
(Austria)
Capacity 30 MW)
Capacity 150 MW) (ILLWERKE Hydro Scheme)
These are high-head peak load stations producing a total of about 390 million kWh p.a.
So far as is known almost the entire output is exported to the German grid but there are reports of supplies being given to the following local plants:-

(1) Heinkel plant S.E. of GASCHURN
(2) Allgemeine Stahlwerke plant N of St. GALLENKIRCH.
(3) Daimler Benz plant at VANDANS. The magnitude of these supplies is not known. The stations are believed to have been recently completed - possibly in the last 6 months.

5. KAPRUN
ORGLERBODEN
(Austria)
Capacity 160 MW)
Capacity 30 MW) (TAUERN Hydro Scheme)
These are high-head stations producing a total of about 750 million kWh p.a. The disposal of the energy produced is not known for certain but it is believed that it is mostly supplied to the Austria aluminium industry - particularly to the large new plant at BRAUNAU.
The stations are believed to have been completed in the last 6 months.

6. OBERNBERG
ERING
SIMBACH
(Austro-German frontier)
Capacity 40 MW)
Capacity 40 MW) (INN Hydro Scheme)
Capacity 40 MW)
These are low head flow stations producing a total of about 600 million kWh p.a. almost the whole of which is believed to be supplied to the new aluminium works at BRAUNAU. Construction of the stations was reported to have started in 1939 and it is known that Obernberg was nearing completion at the end of 1943. It is possible that all three stations have been completed in the last 6 months.

The only reports of a station being built for a "secret" purpose is CX.12204/P.5/3676 of 26/8/43 which tells of the construction of the largest wind tunnel in the Reich (8m x 8m) at OETZ in the Tyrol which is to use 100,000 HP from an enormous water power station on the AACHE river. The speed of flow in the tunnel is to be faster than the speed of sound.

It is believed that this report may have some connection with the known hydro-electric constructional work in the OTZTAL but the power said to be required by the wind tunnel appears fantastic.

/N.B. There is a village called OETZ (ÖTZ) on the R. ACHE (ÖTZTAL) about 25 km downstream from LANGENFELD (where a large hydro-electric station is believed under construction) and about 5 km from the confluence of the INN/

MEMORANDUM FOR MAJOR PARKER:

Subject: Large power plants.

1. The following power plants have been indicated as being large ones:

(a) Grosskraftwerk Golpa, Zschornewitz. This is the electrical power plant for both Halle and Leipzig as well as the surrounding territory. It is a very large plant with 15 tall smokestacks. Coordinates: N 51°43'; E 12°24'.

(b) Sachsenwerk, Nieder Sedlizt near Dresden. Coordinates: N 51°; E 13°50'.

(c) Persenbeug, Lower Austria. Coordinates: N 48°12'; E 15°05'.

(d) Lavamuend, Carynthia. Coordinates: N 46°38'; E 14°56'.

They are pre-war power plants but their existence is being mentioned in view of your recent inquiry.

Interrogated: 6824 DIC/MIS, 13 Dec 44.

I. Preamble

P/W is a friendly 32 year old electrician from VIENNA. He has been employed by the SIEMENSWERKE since 1931, but as he was always on the road installing high tension lines, and reported only to the works assignment office on NIEBELUNGEN GASSE 8-11, he was unfamiliar with the home concern. Because all "indispensable personnel" lists were cancelled in Jul 44, he received his orders while on a trip when it was too late for his firm to have him reclassified and he was called up in Aug 44.

Reliability: B-2 (Source good, probably true report)

HYDRO-ELECTRIC WORKS

Since the war there has been a high priority on electric power installations for the S Austrian and N Yugoslavian districts. All the hydro-electro and steam-power works were combined into a ring network, which delivered the current to this overland ring from which it was transmitted to the different users. This Austrian network was connected with the German ring so that now practically all of GERMANY and AUSTRIA is supplied by this centralized network. Because the power available was not enough, new stations had to be constructed for S AUSTRIA and N YUGOSLAVIA, between which there were 2 distinct nets; the DRAU and the MUR. In both of these nets are 4 combined hydro-electric works two of which are for the MUR network, located at LEOBEN, 15'05" E, 47'24" N, which acts as the head station. It has 3 turbines running. The other is located at GÖSTING, which is at the end of the chain. The 2 intermediate stations are not known. The DRAU (DRAVA) chain consists of the SCHWABECKER station which acts as the head station, fully completed since 1943, running with three 24 MW powered turbines, producing about 1,000,000 KW. The 2nd in the chain is at LAVAMÜND, having 2 turbines, but with only one in operation. The 2nd turbine was still unfinished in Jul 44, because of material shortage. No one knew when it would be finished. This is also to have 24 MW power. The 3rd in the chain, UNTERDRAUBURG, has two 22 MW turbines operating; one since May 44, the other since Jun 44. Another turbine of the same capacity has not been completely installed. Preparations for the works was begun in the fall of 42; the construction, however, did not commence until the early part of 43. A new RR bridge up stream from this project, started in 41 or 42, was completed in Jan 44. The works at FALL were completed by the Yugoslav government before the war, and consists of 3 old type turbines made in Jugoslavia with a probable output of 70,000 KW.

OTHER ELECTRIC PLANTS

TRIFAIL, YUGOSLAVIA

This works has 3 turbines, only 2 of which are operating, one of 22 MW, the other of 18 MW, both producing about 40,000 KW. Installation of 100 KV transformers on the opposite side of the River SAVA had begun in Feb 44.

REICHENBURG

Steamworks with 1 turbine operating, power unknown.

PARTHENNEN WERKE, PARTHENNEN, Austria. 10'04" E, 46'58" N.

The proposed largest Hydro-electric plant in AUSTRIA is being constructed at the above location. It is supposed to have 6 or 7 turbines each with a capacity of at least 24 MW running under high pressure. P/W received this information from other SIEMENS electricians who had done some work on this project.

Figure D.279: 6824 DIC/MIS/NOI-474. 20 December 1944 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)]. “Since the war there has been a high priority on electric power installations for the S Austrian and N Yugoslavian districts. All the hydro-electric and steam-power works were combined into a ring network.... Because the power available was not enough, new stations had to be constructed for S AUSTRIA and N YUGOSLAVIA....”

Werner Grothmann on enrichment of U-235 [Krotzky 2002]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

[S. 6] Ich weiß allerdings nicht, woher das Material kommen sollte, denn unsere eigene Anlage im Erzgebirge lief ja auch erst ganz kurz und lieferte nur sehr wenig, wie ich hörte.	[p. 6] However, I do not know where the material came from, because our own plant in the Erzgebirge ran only very briefly and delivered very little, as I heard.
[S. 32] Die erste Schwierigkeit bestand in der Herstellung des Materials, also des Sprengstoffes. Das hat sich bis wenige Monate vor Kriegsende auch nicht drastisch verbessern lassen. Erst für 1946 rechneten wir eigentlich mit der Serienproduktion von Atombomben.	[p. 32] The first difficulty lay in the production of the material, the explosive. That did not improve dramatically until a few months before the end of the war. We did not expect mass production of atomic bombs until 1946.
[S. 33] Auch ich habe manches erst sehr spät erfahren und einiges auch erst nach dem Krieg. Zum Beispiel die Sache mit der Anreicherung. Es stimmt wirklich, dass die Reichspost 1944 die großtechnische Trennung der erforderlichen Substanzen für die Bombenfabrikation hinbekommen hat. Es war von Ardennes Verdienst. Die Einrichtung, wo das lief, lag weit außerhalb Berlins und ist vermutlich nach Kriegsende unter russischer Aufsicht noch eine Weile weiterbetrieben worden. Später hat man angeblich die Anlagenteile abgebaut und in den Osten gebracht. Vielleicht stehen die heute noch irgendwo herum. Die Tarnung für diese Anlage war hervorragend, weil sie trotz ihrer enormen Größe nicht auffiel. Das Beste war aber, dass überhaupt kein großer Personalaufwand betrieben werden musste. Das erzeugte Material war aber nur für die Reichspostforschung vorgesehen. Diebner hatte seine—ebenfalls begrenzten—Quellen und wir konnten für unsere Projekte kurz vor Kriegsende auch auf eigene Anlagen zurückgreifen, die aber auch noch lange nicht soviel liefern konnten, wie wir damals wünschten. Die gesamten Mengen kann ich nicht nennen, sie waren nicht umwerfend.	[p. 33] I also learned many things very late, and some things only after the war. For example, the matter of enrichment. It is true that in 1944 the Reichspost achieved the great technical separation of the necessary substances for the bomb production. It was thanks to Ardenne. The facility where it ran was far outside of Berlin and probably continued to operate for a while after the end of the war under Russian supervision. Supposedly they later dismantled the plant parts and brought them to the east. Maybe they are still around somewhere today. The camouflage for this plant was outstanding because it did not attract attention despite its enormous size. The best thing, however, was that a large workforce was not necessary. The material produced was, however, intended only for Reichspost research. Diebner had his—also limited—sources, and we were able to use our own equipment for our projects shortly before the end of the war, but they could not deliver as much as we wanted then. I cannot name the total quantities; they were not overwhelming.

[S. 36] Frau Beinhorn hat ihn uns empfohlen, weil der rund um die Uhr arbeiten konnte und, wie es schien, nie müde wurde. Diebner hat ihn mal [deshalb] als das wandelnde schlechte Gewissen seiner Kollegen bezeichnet. Schwietzke hat [...] auf die Frage nach dem Energiebedarf für eine bestimmte Anlage gesagt, das, was wir da reinstecken, bekommen wir bald hunderttausendfach zurück.

[p. 36] Mrs. Beinhorn recommended him to us because he could work around the clock and, as it seemed, never become tired. Diebner once [therefore] described him as the walking guilty conscience of his colleagues. Schwietzke said [...], when asked about the energy requirements for a particular installation, that what we put in there will soon come back a hundred thousandfold.

[Grothmann stated that he knew very little about where or how enriched uranium was produced, but he gave several important clues:

- The Reichspost had at least one U-235 enrichment facility that was located “far outside Berlin.” For security, that facility would likely not be part of some other facility, but for convenience, it might be located near another relevant facility. Most uranium ore in Germany was processed at Auer in Oranienburg, approximately 35 km north of Berlin, so that is one possible location. The Reichspost had major research facilities in Miersdorf (now part of Zeuthen) approximately 22 km southeast of Berlin, Kleinmachnow 19 km southwest of Berlin, and Manfred von Ardenne’s mansion in Lichterfelde approximately 12 km southwest of central Berlin, so those are other possible locations [Zeman and Karlsch 2008, p. 12]. Grothmann said that the enrichment facility used von Ardenne’s designs, which suggests that it was electromagnetic enrichment similar to the U.S. calutrons at Oak Ridge. (Von Ardenne was an expert on electromagnetic manipulation of charged particles in electron microscopes and television picture tubes, and is known to have designed electromagnetic enrichment devices.) The facility was noteworthy for its “enormous size,” which also suggests electromagnetic enrichment; uranium ions are separated out in low-density ion beams that travel up to several meters each, so hundreds of such bulky machines might be required to function in parallel. This facility became fully operational no later than 1944, or 1943 if it supplied fuel for what Grothmann said was a failed autumn 1943 test in the North Sea.

- The SS had at least one U-235 enrichment facility in the Erzgebirge region, but Grothmann did not provide any clues about what enrichment method(s) it used. This region was heavily mined for uranium by the Russians after the war. If the SS chose to locate an enrichment facility there, it suggests that Germans were mining uranium there during the war.

- Werner Schwietzke apparently designed and promised great returns from a special installation; he is known to have spent the war developing uranium gas centrifuges with Werner Holtz for the Army Ordnance Office [p. 3542].

- Kurt Diebner had sources of enriched uranium that were independent of the Reichspost and SS facilities, but Grothmann did not elaborate. Those might be (1) Schwietzke’s centrifuges, (2) centrifuges in the Hamburg/Kiel area managed by Paul Harteck, Wilhelm Groth, and Konrad Beyerle, (3) the “isotope sluice,” a centrifuge-like device developed by Diebner’s close collaborator Erich Bagge, and/or (4) presently unknown additional sources.

It is important to find more information about all of these uranium enrichment facilities. It is also possible that there were other important enrichment facilities that Grothmann did not know about or did not mention in the interviews.]

Karl Cohen to Philip Morrison. 7 August 1944. [NARA RG 77, Entry UD-22A, Box 168, Folder 203.11 Tech-Countermeasures + RW 1943–1944]

1. I have your memo of August 1. Pursuing your thought that we should take definite steps to counter enemy use of a device, I add the following suggestions:

4. Most of the threat would disappear if Upper Silesia were neutralized. If the Russians are not able to force a rapid decision in this sector, we should urge heavy strategic bombing of all power plants in this region from Russian bases.

8. We have ample evidence to justify bombing the Auer works on a strategic basis. This firm certainly has a key role in any program of consequence, and should be given special attention. Have we reconnaissance pictures of Auer?

[See document photo on p. 3713.

Based on intelligence not specifically described here, Leslie Groves's Foreign Intelligence Unit believed that there were important German nuclear weapons plants in Upper Silesia. They also recommended bombing Auergesellschaft in Oranienburg, which the U.S. ultimately did.]

Countermeasures
Feb 7

MEMORANDUM TO: P. Morrison August 7, 1944.

FROM: K. Cohen

1. I have your memo of August 1. Pursuing your thought that we should take definite steps to counter enemy use of a device, I add the following suggestions:

2. A defense group prepared not only for scientific detective work, but also for the more obvious civil defense measures, should be set up in England immediately. It must be mobile and equipped to determine what area after an explosion is still habitable. The nucleus of specialists experienced in field tests which has been established for Site X can furnish the cadres. Adequate attention must be paid to the psychological side of the defense group. It should be given a false front of the best-publicized scientists of both countries and given a good newspaper name like "Atomic Warfare Defense Section". For morale purposes it would be most important for the public to feel that we were well prepared in advance. The "false-front" need not be notified for the present.

3. The above measures are not alarmist; they are prophylactic, and are dictated by the possibilities shown in our last report.

8-7-44

4. Most of the threat would disappear if Upper Silesia were neutralized. If the Russians are not able to force a rapid decision in this sector, we should urge heavy strategic bombing of all power plants in this region from Russian bases.

5. Personally, I would prefer this procedure to the bombing of Bisingen on present evidence. At any event, Bisingen should not be attacked without detailed reconnaissance and analysis.

6. Reflection on last week's conversations highlighted the following points

a) It is possible for the enemy to produce devices at a dangerous rate.
b) We have no direct evidence that he is doing so.

a) and b) together infer that the enemy is probably doing nothing. But this is not enough! We need a crucial experiment.

7. In this respect the reaction of the enemy to an 'accidental' (i.e. incidental to other attacks) bombing of his metal stores, or of Auer, would be most instructive.

8. We have ample evidence to justify bombing the Auer works on a strategic basis. This firm certainly has a key role in any program of consequence, and should be given special attention. Have we reconnaissance pictures of Auer?

A.D.I. (K) Report No. 113A/1945. Suspected ‘V’ Weapon Factories—Germany and Poland. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

UNDERGROUND FACTORY, WIELICZKA, POLAND.
(March 1944).

15. A Polish refugee, who had worked in the Wieliczka area until March 1944, mentioned that towards the ends of 1943 the Germans had installed a plant for secret weapon production in a salt mine to the South-West of the town on the northern side of the Wieliczka-Swoszowice road at 49^o 58’ 50” N., 20^o 3’ 0” E.

16. The entrances to the site were guarded by black uniformed guards and the workers, who were all interned Jews, were never allowed to go out for air; it was understood that the mortality rate was very high as a result of these restrictions and the unhealthy working conditions.

17. Informant added that many of these workers and some of the machinery had been transferred to Wieliczka from another secret weapon factory situated to the North-East of Debica at approximately 50^o 8’ N., 21^o 33’ E. The local Poles were fairly sure that Debica was producing V.1’s in 1943 as these were tested in the neighborhood and fell in the town of Sandomierz (50^o 30’ 40” N., 21^o 46’ 00” E.)

[See document photo on p. 3717.

This report described an underground plant in Poland that seemed much more secretive than standard V-1 and V-2 plants. If it was more secretive, was it producing modified missiles, or unusual warheads for missiles, or other advanced weapons?]

SECRET.

UNDERGROUND FACTORY, OBRIGHEIM. (MANNHEIM AREA).

9. An undated interrogation report from a French source mentions the existence of an underground factory at Obrigheim (49° 21' 10" N., 9° 05' 40" E) where 'V' weapons or perhaps poison gases were being manufactured.

10. It was understood that this underground factory was on or near the site of a former plaster works and its personnel, who were accommodated in barrack huts, included a number of conscripted Frenchmen drafted from Strasbourg.

SUSPECTED 'V' WEAPON FACTORY, SCHÖNEBECK AN DER ELBE.
(January 1944).

11. A German Army P/W had received a letter from his wife in January 1944 in which she said that a factory at Schönebeck an der Elbe was making parts for secret weapons.

12. P/W did not know the name of this factory but believed that it lay on the eastern side of the Friedrich Strasse between pinpoint 742862 and pinpoint 746866 GSGS 4414 Sheet 3936.

SUSPICIOUS U-BOAT PEN, BREMEN.
(August 1944).

13. A Luxembourg engineer interrogated on the Continent had paid a visit in August 1944 to a U-boat pen under construction on the eastern bank of the River Weser, 16 miles North-West of Bremen, at 668987 GSGS 4081, Sheet 47.

14. At the time of informant's visit the roof of the concrete pen was being increased in thickness from 15 ft. to 24 ft. and the side walls were being similarly strengthened. He heard that it was originally intended to be used for U-boat assembly but that it was probably to be handed over to the G.A.F. and used for the manufacture of 'V' weapons.

UNDERGROUND FACTORY, WIELICZKA, POLAND.
(March 1944).

15. A Polish refugee, who had worked in the Wieliczka area until March 1944, mentioned that towards the end of 1943 the Germans had installed a plant for secret weapon production in a salt mine to the South-West of the town on the northern side of the Wieliczka-Swoszowice road at 49° 58' 50" N., 20° 3' 0" E.

16. The entrances to the site were guarded by black uniformed guards and the workers, who were all interned Jews, were never allowed to go out for air; it was understood that the mortality rate was very high as a result of these restrictions and the unhealthy working conditions.

17. Informant added that many of these workers and some of the machinery had been transferred to Wieliczka from another secret weapon factory situated to the North-East of Debica at approximately 50° 8' N., 21° 33' E. The local Poles were fairly sure that Debica was producing V.1's in 1943 as these were tested in the neighbourhood and fell in the town of Sandomierz (50° 30' 40" N., 21° 46' 00" E.)

In the Zipfer Brauerei (brewery) in Zipf, Upper Austria, some secret and important war production is taking place. This production, which might be in connection with the secret weapon, is taking place in the underground parts of the brewery.

From John Lansdale, Jr., to Leslie Groves. Subject: Extract from ASF Intelligence Bulletin No. 10. 1 July 1944 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2 GERMANY: US Wartime Positive Int. (July–Oct. 44)]

The following is taken from Part V, paragraph 2, page 11 of ASF Intelligence Bulletin No. 10, dated 28 June 1944:

"When on furlough in December 1943, visiting relatives near Voecklamarkt, Austria, P/W saw a very secret factory at Redl Zipf in a wooded ravine, about 200 meters north of the Redl Zipf RR station on the RR between Voecklamarkt and Voecklabruck. The people living in the vicinity believed poison gas or gas for secret weapons was being manufactured here but no one had definite information because workers were not from the neighborhood and the plant was very closely guarded by Gestapo in uniform and in plain clothes."

Report of Interrogation
PW RAAB, Johann
Grenadier, Gren.Regt 305

11 October 1944
IO Captain Campbell

Veracity and estimate of personality: Believed to be reliable. PW is a thirty-year old Austrian, formerly a traffic official (Fahrdienstleiter) for the Deutsche Reichsbahn in Austria. He was inducted into the German Army 12 February 1944. PW is intelligent, observant and cooperative. The information contained herein was gathered by PW as a result of personal observation of the rail traffic between the installations involved and conversations with friends and acquaintances acquainted with the plants.

NOTE: The information contained in this report is only preliminary and as such, incomplete. A full report, together with sketches of installations discussed herein will be submitted 12 or 13 October.

Information obtained: In late September and early October 1943 PW began to notice an unprecedented amount of activity on the rails between
Redl Zipf (N 48°02'07"), Stadl-Paura (N 48°04'40"), Ebensee (N47°48'40")
(E 13°04'40") (E 13°52' 40") (E13°46'30")

and Lenzing (N47°57'30"/E13°39'30"), all in the Salkammergut. All this activity centered around the former Redl Zipf brewery storage cellars which are cut out of the limestone shale in a nearby hill. The inmates of a nearby concentration camp as well as numerous foreign and native workers were called in to enlarge the working area inside the hill and to lay a road bed for a railroad spur running into the installation. Concrete was poured for the flooring and the whole interior section was remodeled to provide work shops. Power lines were brought in from nearby Timelkam providing a current of 15,000 volts, and vast quantities of special equipment (discussed below) began to arrive even before the place was ready for production. The German engineers in charge as well as their underlings were all informed that the installation had to be ready for full production within a period of four months. While this was going on at Redl Zipf the artificial fiber plant in nearby Lenzing (Zellwolle Fabrik A.G., cf. report 1219, 1 May 1944) was being remodeled for a change over in production. The nature of this remodeling was unknown to PW or any of his acquaintances but in light of its contributions to the Redl Zipf installation it is apparent that the conversion wad made to subordinate the activity of Zellwolle A.G. to Redl Zipf.

The engineers in charge of construction and production as well as almost all of the workers were Germans from the Altreich and practically all of them (total number of workers estimated at 2000) were trusted party members wearing the golden party membership insignia. PW became acquainted with the manager, Technischer Ingenieur Helmut Novotny as a result of damage to some of the equipment being shipped to Redl Zipf. Novotny was on the scene from the very beginnings of the construction period and stayed on after it got into production. Another personality whom PW remembers well was a man named Hollstein, also German, but Hollstein's visits became sporadic after the plant was completed. In a

SECRET

conversation with Novotny PW learned that there had previously been two similar installations of the same type in Germany itself--one in Sandhofen, north of Mannheim and one in Wiesoppenheim, just west of Ludwigshafen. Both these installations had been destroyed as a result of Allied bombings, but it was felt that this had occured more or less by chance as everything else in the area suffered equally, and the above mentioned installations were above ground, unlike the Redl Zipf plant.

The product of the firm is known to the workers only as "liquid gas" and, based on PW's knowledge of the raw materials delivered to the plant, it would appear to be some kind of explosive. Among the raw materials delivered to the plant were large quantities of coal (not for power, because all power was electric), bauxite, which came in Hungarian R.R. cars, lead, beryllium, tungsten, lye (which came from the Solvay firm in nearby Ebensee (this firm, in turn, was importing large quantities of thorium from Hungary and elsewhere in the Balkans. Lye and cellulose in large sheets came from the Zellwolle A.G. in Lenzing. From Ebensee also came 25 to 30 kilo sacks of a substance described on the bills-of-lading as Chlorzont (an ash-gray colored powder).

The equipment inside the plant consists of circa 200 boilers of unusual construction in that they are completely lined with some argillaceous material and covered over on the outside with some white metal, name of which is unknown to PW, but it is supposed to be a non-magnetic substance. These boilers are situated in different compartments and are connected by a system of pipes and conduits running between the sections and through the concrete walls. PW himself only saw the inside of the plant on one occasion, before completion, when he brought some materials into the installation. His other information comes from his wife's brother who was employed in the plant. The gas, or liquid, prepared was stored in large high-pressure cylinders about $3\frac{1}{2}$ to 4 meters in height and $1\frac{1}{2}$ to 2 meters in diameter. PW believes they were constructed of more than usual strength steel. They too, as well as all connections and valves, were lined with an earthenware type coating.

The product, when ready for shipment, was sent to an already established munitions factory in Stadl Paura (cf. report 1219, 1 May 1944--PW's information on this plant differs substantially from that given in above ~~this~~ report and will be covered fully in final report). Great care had to be exercised in transferring the liquid from the high-pressure containers to the tank cars. The hoses used for making the transfer were made of rubber impregnated fibers reinforced on the outside with flexible bands of the same white and allegedly non-magnetic metal used in the construction of the boilers referred to above. Even the nozzles were lined with an earthenware coating to prevent any contact of the liquid and the metal. The tank cars themselves were extraordinary.They were completely constructed of a clay or heavy earthenware substance and were bedded on thick felt cushioning. They may have been reinforced with metal inside the walls of the tanks, but no metal was visible from the outside. There were 6 of these tank cars, each containing 250 hektoliters and they had been specially built by a firm in Ludwigshafen. They were used only on the Redl Zipf--Stadl Paura run. On one occasion

SECRET

Figure D.286: Report of Interrogation PW RAAB. 11 October 1944 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2 GERMANY: US Wartime Positive Int. (July–Oct. 44)].

DECLASSIFIED
Authority NND 917017

NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2

SECRET

PW examined the residue clinging to the underside of a tank car lid after it had returned from Stadl Paura. He found a number of lumps of a thick gummy grayish substance with traces of what looked to him like oil on the surface. It was absolutely odorless. He was surprised at the grayish color for he had been told that the gases themselves, when in liquid form, were of a green or yellowish color. He surmised that when pressure was released radical changes took place in the substance.

It is noteworthy that the workers in the plant complained of loss of appetite and one of them, a brother in law of PW, said he could no longer enjoy a regular meal. Peasants in the vicinity were required to make regular delivery of whole milk for the workers. All workers were absolutely forbidden to drink any alcoholic beverage, even beer, whether on or off duty. Brother in law of PW confessed that he had tried a few glasses of beer anyhow, but to his surprise found it distasteful. He felt that the gases or something else in the atmosphere of the installation were responsible for this. Other workers were undergoing the same experience. However, as this brother in law was receiving over 50RM per week for the relatively unskilled work he was performing (transferring the liquids from containers to tank cars) he was not complaining too much about his health.

On one occasion, when PW tried to draw Novotny out a little about the nature and use of theliquid gas Novotny put him off with what the PW considered fairy tales about "freezing gases" and "explosives which detonate with unheard-of force," or "weapons which will stop motors from functioning." PW believed that Novotny was stringing him along just to be polite rather than telling him point blank that it was none of his business.

Later, before PW was inducted into the army, the RR delivered 4 large dynamoes (marked "Henkel") and 16 to 18 smaller dynamoes (marked "Bosch") to the plant. He wondered what these were for inasmuch as the plant already was getting 15,000 volts from Timelkam. Included with these was a large variety of miscellaneous electrical equipment including transformers and items which PW had never seen before. He knew that electrical furnaces, albeit small ones, had been installed in the plant and felt that perhaps these dynamoes were used to furnished additional power for them .

PW learned from a worker at Stadl Paura that "a new type shell casing " was being turned out. So far as he recalls this shell case was of a size suitable for use in the largest field artillery pieces and was made of some kind of white metal. Whether or not there was any connection between these shell casings and the liquid gases being delivered there PW does not know.

End of preliminary report.

He felt that the gases or something else in the atmosphere of the installation were responsible for this. Other workers were undergoing the same experience. However, as this brother in law was receiving over 50RM per week for the relatively unskilled work he was performing (transferring the liquids from containers to tank cars) he was not complaining too much about his health.

On one occasion, when PW tried to draw Novotny out a little about the nature and use of the liquid gas Novotny put him off with what the PW considered fairy tales about "freezing gases" and "explosives which detonate with unheard-of force," or "weapons which will stop motors from functioning." PW believed that Novotny was stringing him along just to be polite rather than telling him point blank that it was none of his business.

Later, before PW was inducted into the army, the RR delivered 4 large dynamos (marked "Henkel") and 16 to 18 smaller dynamoes (marked "Bosch") to the plant. He wondered what these were for inasmuch as the plant already was getting 15,000 volts from Timelkam. Included with these was a large variety of miscellaneous electrical equipment including transformers and items which PW had never seen before. He knew that electrical furnaces, albeit small ones, had been installed in the plant and felt that perhaps these dynamoes were used to furnished additional power for them.

PW learned from a worker at Stadl Paura that "a new type shell casing" was being turned out. So far as he recalls this shell case was of a size suitable for use in the largest field artillery pieces and was made of some kind of white metal. Whether or not there was any connection between these shell casings and the liquid gases being delivered there PW does not know.

End of preliminary report.

[See document photos on p. 3719–3721.]

Philip Morrison to Joseph Volpe. Evaluation of Documents in the Washington Office—October 19, 1944 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.60-2 Germany: Summary Reports (1945–1946)]

[...] 7. The long Prisoner of War reports on Redl Zipf have already been discussed by Dr. Tolman. It is reasonably certain that this is not a plant of interest to us [Manhattan Project] but may be of interest to some of the Chemical Warfare officers. [...]

[From this remarkably detailed PW report, it sounds as if something extraordinary was being produced at the Redl Zipf plant, yet there is still not enough information to tell exactly what that product was. It is possible that work conducted at this plant was one (or more) of the following:

- Production of uranium hexafluoride for U-235 enrichment. Uranium hexafluoride is corrosive to most materials except nickel, aluminum to a certain extent (the white metal described in these documents may have been nickel, aluminum, or an alloy containing one or both of those metals), and certain ceramics (such as the earthenware or earthenware-lined containers described in these documents).
- Enrichment of U-235 in uranium hexafluoride via gaseous diffusion, if the "circa 200 boilers of unusual construction" that were "connected by a system of pipes and conduits" were gaseous diffusion cells containing nickel diffusion membranes under high pressure.
- Enrichment of U-235 in uranium hexafluoride via centrifugation, if the "boilers of unusual construction" were uranium gas centrifuges.
- Chemical reprocessing to purify Pu-239 from neutron-irradiated U-238.
- Chemical reprocessing to purify U-233 from neutron-irradiated Th-232.
- Production of a nerve agent. Sarin, cyclosarin, and soman (but not tabun) contained fluorine, which made them corrosive to metals other than nickel or possibly aluminum.
- Production of a blistering agent. Mustard and some other blistering agents contained chlorine, which made them corrosive to most metals.
- Production of a fuel-air explosive, such as a mixture of coal dust and liquid oxygen, or coal dust and a corrosive nitrogen-based oxidizer (nitric acid, nitrogen tetroxide, etc.).
- Production of a corrosive nitrogen-based oxidizer (nitric acid, nitrogen tetroxide, etc.) for rocket propellant.
- Production of a fuel for rocket propellant (hydrazine, etc.).

Any of the above options are possible based on the PW report. Of these options, arguably the best fit might be uranium enrichment via gaseous diffusion or centrifugation of uranium hexafluoride. Manhattan Project personnel certainly seemed to think the Redl Zipf plant could be doing nuclear-related work, which is why they included it in their files and apparently spent some time analyzing it. On what grounds was this PW report ultimately dismissed as not being nuclear-related?

The same information was repeated in the final version of this PW interrogation report, Report 1349, Report from Captured Personnel and Material Branch, 17 October 1944 [AFHRA 25177 electronic version pp. 923–935].

There were many other wartime intelligence reports about very secret, high priority, and extremely mysterious work that was conducted at Redl Zipf [e.g., AFHRA electronic versions A6091 p. 1287l, 25082 pp. 106–108; 25177 pp. 919–951; 25216 pp. 385–386].]

LULLABY from Czechoslovak refugee who worked in the factory.

Date of Information
6.2.45

Reliability
Good

Subsource is available for interrogation until 20 Feb. 45. Urgent comments are requested.

1. The secret name of the factory is SCHLIER. All transports for this factory are delivered under this name or "Zentralbauleitung Redl-Zipf". The number of workers employed in this factory is not known exactly to me, but I guess that about 1,000 men are now working there. The camp of these workers is situated in the buildings of the brewery in ZIPF. The brewery works only in a restricted measure. These workers are specialists—German only.

2. The factory has no name. It belongs to the Hermann Göring concern, LINZ (Austria).

3. High-explosive gas is manufactured in the underground tunnels and stored in vertical kettles (20 x 4 m), the pressure being 50–100 atm. These kettles are in the underground tunnels as well.

4. Two entrances lead to this underground factory and, out of these corridors, other corridors were hewn in the rock which lead into working rooms, the number of these being 23. From these rooms are pipe lines leading into the kettles. Some rooms have 2 or 4 (one has even 8) kettles. The total number of kettles I do not know.

5. These kettles, made of steel, are vertical, hewn into the rock under the surface of the corridors and on the top of the kettles is a layer of ash-like material. The whole kettle is cemented into the rock.

6. I have seen machines in 4 rooms only. These 4 rooms were the biggest—12 m width, 100 m length, 5 m high. The firring of these machines, where I helped, lasted one month. In each of these rooms were two machines that looked like huge pumps—dimensions 3 m width, 3 m height, 5 m length. Other installations in these rooms were a steel ball, walls 7 cm thick, 2 m diameter (I know the thickness of this ball as other workers were cleaning the interior of the ball). This ball has not been of one piece, but welded out of several square pieces. Into the ball leads a pipe, the diameter being about 50 cm and another pipe of the same dimension which leads out opposite the first pipe. Two pipes 10 cm diameter lead into a measuring apparatus which has been sufficiently accurate to measure 1/260th of a gramme. This apparatus I suppose has been devised to measure the pressure and probably other qualities of the product.

7. This product has been referred to by German personnel as “Masse”.

8. The ball rested on an iron pedestal and under this pedestal the aforementioned measuring apparatus has been placed. This apparatus has been of a sort of weigh[ing]. During the time of fitting one Russian prisoner left a chisel, probably on purpose, a chisel in this weigh so that the apparatus would not function, the chisel staying upright. He has been shot. This apparatus had several dials which were connected with a camera. This camera has been connected with a “Prüfungsraum” situated on the top of the rock and separated from the working rooms. This ‘Prüfungsraum” was in a pill-box, camouflaged with dry trees painted green. In the same manner has been camouflaged the whole rock on a surface of about 300 m x 300 m. On the rocket has been put a layer of cement, about 30 cm, and in this layer the dry trees stuck in and sprayed with green paint.

9. At the first trial producing the “Masse” an explosion occurred and a fire broke out lasting five minutes. A flame shot out of the tunnels, white in colour (Stichflamme) and a temperature of 3000 ^{o}C—as I heard from the Germans—all the brass, aluminium and copper parts of machines disappeared. The repair lasted for three months (the factory has been built from April 1943–May 1944). All the occupants in the rooms were killed—my party removed 9 bodies, completely unrecognisable, 70 cm long.

10. The other rooms were much smaller, about 3 x 3 x 3 m and some were only enlargements of the corridors. There were a few machines which had been transported there in parts so that I could not guess what sort of machines they were when fitted together. Ten rooms were probably larger, but always behind a curtain. In one of them has been probably a power station, as different electric material has been transported inside. I guess that chemical products were manufactured as cases from the societies: Vereinigte Chemische Fabrik Kreidel & Heller, Wien XXI, Sebastian Kohlgasse (I know the first exactly as near there I have been working—the factory until XII/1944 has not been hit, though the Vacuum Shell Company on the opposite side of the street is completely destroyed).

11. The daily output of the factory is 4 railway-cisterns. These cisterns resist high pressure. At the closing of the cisterns a white snow-like layer forms itself and the so evaporating gas has a slightly green colour, without any smell and when inhaled is harmless.

12. Locating this factory is helped by the brewery in ZIPF which has a high factory chimney painted green. The two corridors leading underground are immediately at the brewery (see sketch) towards North.

13. The rock in ZIPF, where the factory is, is of sandstone and it happened several times during the construction that the corridors broke down. At the entrance the thickness of sandstone is about 1 m, the deepest corridor is 18 m. On that point is a shaft, the Germans said, 18 m deep.

14. The station REDL-ZIPF is on the main railway line LINZ-SALZBURG.

15. Electricity comes from the power station TIMELKAM situated 20 km to the East of the station Redl-Zipf. The tension is 110,000 V. I worked on the fitting of switchboards. From the transformer station (see sketch) electricity comes to the factory with two high tension wires and two underground cables. Here the tension is lowered to 10,000 volts.

Another high tension wire was being erected to the West as I know there is also a power station in STEINDORF, 20 km to the West from REDL-ZIPF.

16. What I heard, and what the workers think, is that gas for the V.1 weapon is being manufactured in this factory.

17. The postal address of this factory is: Attnang-Puchheim, Postschliessfach 26.

I heard about other factories of this sort, but I have not been there. They are:-

1. The factory in ST. GEORGEN, near LINZ. The secret name of this factory is ESCHE. The postal address: LINZ/DONAU 2 Postschliessfach 999/XX.

2. The factory in MELK, near Vienna. The secret name is QUARZ, the postal address is not known to me.

We were told by the Germans that, upon being asked by relatives etc we have to say that we are in Esche, Quarz etc. Where is this unknown place? At Attnang-Puchheim. Of course, what is being done there, we were forbidden to tell.

3. Another factory of this sort in WIENER NEUSTADT has been destroyed by bombing. Work not resumed.

FLYING BOMB or ROCKET FACTORY
at
Z I P F
(AUSTRIA)

G.S.G.S. (AIR) 5005.

SHEET 4751.

48° 02' 22" N.
13° 30' 12" E.

SORTIE: 60PR/636.
PRINTS: 3023 to 3025.
4043 to 4049.
5011.
SCALE : 1/8,500 (36")
1/51,000 (6")
DATE : 7 August 1944.

Reports have stated that:

(a) Flying bombs are produced in a former brewery 15 miles from SALZBURG in the direction of VIENNA.
(b) A bomb-filling factory is situated in a brewery which lies at the foot of a hill known as ZIPF; the factory being partly underground.
(c) Rockets 10m. long and 4m. broad, were seen in a salt mine at REDELZIPF.

Photographs which cover the village of ZIPF, which is situated 27 miles N.E. of SALZBURG, show a large brewery adjacent to the hillside. From the well-defined tracks at the foot of the hill and the existence of dumps of spoil, it is evident that some excavation has been made in the hillside; furthermore a newly constructed siding leads from the main line to what are probably the entrances to the excavation. Judging by th well defined roads and tracks it seems that not only is the brewery closely allied to t underground shops, but that the whole village has been taken over for administration, billeting and perhaps part production.

As it is to be expected there are no external indications as to what the finished product is other than the presence of three dumps of curious unidentified objects, "egg like" in shape, and measuring approx. 10 ft. by 6 ft. The most significant feature in complex, however, is the presence on the siding, near the entrances to the underground wor of a special type of tankcar identical with those seen at PEENEMUNDE, also at least 5, probably 7, similar tank cars are situated on the works siding where it leaves the main
The plant is obviously active for in addition to the indications mentioned previou smoke is issuing from the brewery chimney, numerous M.T. are parked near a large buildi two M.T., and some personnel are in motion.

M.A.P.R.W. 11 August 1944. Report No: MI.311

CONFIDENTIAL

Figure D.297: [AFHRA Mediterranean Allied Air Forces Reel 189, No. 1391 Zipf GN 5061]

BIOS 31. *Rocket Developments in South Germany and Austria.* pp. 35–37.

Target: Steinbruchverwertungs G.m.b.H.
Betrieb Schlier

Location: Brauerei Zipf, Redl. N.49 XV2954
(U.S. zone)

Nature of Target: Underground liquid oxygen plant
and firing station for static
proof of A.4 rocket motors.

Date visited: 24.8.45.

Personnel interviewed: Dr. Kretz, (E), the owner
of the brewery.
Available at the brewery.

1. The brewery's storage vaults, which were constructed in the side of a hill, had been used by the above-named organisation for the erection in 1943 of an underground liquid oxygen plant.

This plant consisted of seven units, operating on the Linde principle, capable of producing 80 tons of liquid oxygen per day.

Each unit comprised a compressor, alkali absorption towers for removal of CO_2, and a still for separation of liquid oxygen and nitrogen.

The compressor, built by Borsig, operated in five stages and developed 600 Kw. Compression to 160 atms. was attained.

The nitrogen was expanded after separation from the oxygen, giving a recovery of 10 per cent. of the power input. After running off the liquid, residual gaseous oxygen was bottled.

The liquid oxygen was pumped from the plant's storage tanks into specially constructed railway wagons, each holding 30 tons. It was stated that the loss by evaporation from these wagons was one ton per day.

Production had been continuous until April 1945, when transportation became impossible on account of disruption of railway services.

The plant had not been attacked by air and was completely undamaged although provision had been made by the S.S. for blowing up the entrances. This plan was frustrated by the early arrival of U.S. ground forces.

Dr. Kretz stated that a similar plant consisting of 15 units had been operating at Saalfield. (Russian occupied zone).

Maintenance of the plant is at present being carried out, pending a decision as to its utilisation. (Redl is in Austria).

2. A static firing station, for testing A. 4 rocket motors, had been constructed on top of the hill. This was directly accessible by a lift from the underground factory, in which the motors awaiting test were stored. (Nine motors, mounted on trolleys running on a narrow gauge railway, were seen). [...]

The whole station was of massive dimensions and solid construction.

Two bursts during firings had occurred since tests commenced in October, 1943. The first of these occurred in February, 1944, and the second which partially destroyed the firing bay, in August 1944, since when no firings had been done.

After the first of these bursts, all iron pipe lines for liquid oxygen were replaced by aluminium, which does not become so brittle at extremely low temperatures.

It was stated by Dr. Kretz that no other rocket work was carried out at the factory. No rocket materials, other than those mentioned above, were discovered by this team.

It is of interest to record that the underground factory contained one "secret room", open to S.S. officials only, in which counterfeit Bank of England notes, from L1 to L50 denomination, were printed.

Visits by other rocket teams to this target are not considered necessary.

[This is one of several Allied reports that described Redl Zipf as just an oxygen production plant (e.g., see p. 4965).

It is possible that part of the Redl Zipf facility did produce oxygen, but if that were the only product of Redl Zipf, that would not be consistent with many of the details provided by PW Johann Raab (p. 3722): (1) long-term toxicity to the workers; (2) extreme corrosivity to all materials except a white metal (nickel, aluminum, or an alloy containing one or both of those metals?) and ceramics; and (3) consumption of large quantities of nuclear-related materials such as lead, beryllium, thorium, etc.

If Redl Zipf were only an oxygen plant, it would also contradict the intelligence report that specifically stated that Redl Zipf was doing work related to nuclear weapons (p. 3728), as well as other intelligence reports that indicated that Redl Zipf had far greater secrecy and security than one would expect of a simple oxygen plant [e.g., AFHRA electronic versions A6091 p. 1287l, 25082 pp. 106–108, 25177 pp. 919–951, 25216 pp. 385–386].

Was the Redl Zipf plant really only producing oxygen the whole time, or was it converted to that later, or only using oxygen production as a cover story? For example, at the end of the war, German industrial plants that had been producing nerve gas were stripped of all evidence and even completely overhauled to appear to have been nothing more than harmless soap factories throughout the war [Jacobsen 2014, pp. 24–29, 73–75].

BIOS 31 was a British report. U.S. officials also personally inspected the Redl Zipf plant after the war (p. 4965). What exactly did they find there? Where are their reports?]

English translation of French intelligence report. 10 June 1944. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2 GERMANY: US Wartime Positive Int. (July–October 1944)]

1. With reference to conversation which Hitler is supposed to have had in a factory in Vienna. Accordingly there are supposed to have been successful in making tractable the disintegration of matter—with a possibility of using it as an explosive—they will only make use of it as a desperate measure (tested during the attack on Kovel?) because when the transformation has begun they do not know how to stop it.

2. On the road from Vienna Neustadt to Neuburg [Neuberg?]—on the side of a small hill a factory or an underground laboratory is located surrounded by barbed wire—guarded by SS troops—workmen are not allowed to enter. [...]

GERMANY - WAR ECONOMY

FACTORIES: ACTIVITIES

Germany 22 May 1944

1. With reference to conversation which Hitler is supposed to have had in a factory in Vienna. Accordingly they are supposed to have been successful in making tractable the disintegration of matter - with a possibility of using it as an explosive - they will only make use of it as a desperate measure (tested during the attack on Kovel?) because when the transformation has begun they do not know how to stop it.

2. On the road from Vienna Neustadt to Neubourg - on the side of a small hill a factory or an underground laboratory is located surrounded by barbed wire - guarded by the SS Troops - workmen are not allowed to enter.

3. In three (3) months a new fighter plane should be ready equipped with a 3,400 H.P. Mercedes-Benz engine, 24 cylinder radio engine with a speed of 800 Klm., armed with 4 cannons of 25 mm. calibre.

4. The manufacture of bombers has recently been cut down in favor of pursuit planes.

5. The factories of Vienna Neustadt have only sustained slight damages from bombing and are working at 90 per cent capacity.

CONFIDENTIAL

#27074. AZUSA. 154 and Dix from 148.

Octopus cables 18 January that partisans report experiments being conducted on atomic bombs at Sopron, Hungary and west of Vienna. We are asking that further inquiries be made discreetly. Meanwhile cable me whether you have had other indications on these localities. Ask Major Furman if Major Ham is still his representative in this Theater.

[See document photo on p. 3747.

This intelligence report may or may not have been talking about Redl Zipf specifically, but it is further confirmation that nuclear weapons development was being conducted in that area.

Experiments "west of Vienna" might refer to research installations at Redl Zipf, Gusen/Bergkristall, Zell-am-See, Lofer, Melk/Quarz, and/or other locations.

What was going on at Sopron (Ödenburg), Hungary? Sopron is approximately 65 km south of Vienna, just across the border into Hungary. Can any other documents concerning wartime nuclear research there be located? It sounds as if the OSS was going to write follow-up reports.]

Zbynek Zeman and Rainer Karlsch. 2008. *Uranium Matters: Central European Uranium in International Politics 1900-1960*. p. 73.

While the uranium treaty was being considered, Bakulin reminded Fierlinger that he had agreed to hand over 38,516 kilograms of radioactive material available on Czechoslovakian territory to the Soviets. Fierlinger immediately gave orders for the transfer of the materials to the Soviet foreign trade organization, Torgpredstvo, and requested that the ministries of industry and foreign trade take care of the transfer. On 14 October [1945], 37,012 kilograms of uranium paints, (containing up to 58.4% uranium oxide [U_3O_8]), were taken away from the Příbram smelting works. On 29 and 30 October, barrels and boxes containing 9,725 kg of 58% uranium concentrate followed. Additional pitchblende from the slagheaps was collected, and the amount of uranium the Soviet Union received from these sources has been calculated at 30.838 tons; only 0.919 tons of uranium was actually mined in 1945.

[Ivan Bakulin was a Soviet official. Zdeněk Fierlinger was the Soviet-installed prime minister of Czechoslovakia after the war.

It seems highly unlikely that over 30 tons of valuable refined uranium was simply being used for paint. Presumably that was just a cover story given by the Germans, Czechs, and/or Soviets.

What exactly was the uranium being used for during the war? Was it for enrichment or for use in a fission reactor? Or had it already been enriched or irradiated in a reactor?

Why was the uranium at Příbram? Among other things, Příbram was home to a large wartime research installation run by the SS and Skoda and directed by Rolf Engel, who was an expert on explosives, implosion bombs, rockets, and related subjects (pp. 4921, 5696).

See the documents on pp. 3752–3754.]

Eing.: 12. JULI 1943

An den
Höheren SS- und Polizeiführer
SS-Obergruppenführer Frank

Prag - Hradschin

Auf Ihr Fernschreiben vom 17.6.1943, das ich zuständigkeitshalber dem Chef der Amtsgruppe C im SS-Wirtschafts-Verwaltungshauptamt - SS-Brigadeführer und Generalmajor der Waffen-SS Dr. Kammler - zugeleitet habe, ist mir von diesem folgendes mitgeteilt worden:

> "Der Truppenübungsplatz Beneschau ist unter Nr. "Prot.42 Up c 1" eingestuft. Aus der letzten Zahl der Nummer "1" ist zu ersehen, dass es sich bei dieser GB-Bau-Nr. um die höchste Stufe in dem betreffenden Sachgebiet handelt, die der GB-Bau überhaupt zu vergeben hat. Es ist mir daher unverständlich, wieso SS-Gruppenführer Frank dahingehend unterrichtet werden konnte, dass der Truppenübungsplatz Beneschau beinahe an letzter Stelle eingestuft sein soll.
>
> Ich habe die Zentralbauleitung Prag angewiesen, sofort diesbezüglich bei den zuständigen Arbeitseinsatzdienststellen Klarheit zu schaffen und im Einvernehmen mit der Dienststelle des Reichsprotektors dahingehend zu wirken, dass raschestens die restlichen Zivilarbeiter zugewiesen werden.

Ich bitte Sie, hiervon Kenntnis nehmen zu wollen.

Der Chef des SS-Führungshauptamtes

H. Jüttner

SS-Obergruppenführer
und General der Waffen-SS.

St. S. VII Pz - 109/43

SS-F.H.A. 51 — 2000. 9. 42.

Figure D.311: In June 1943, Hans Kammler issued an order that the Beneschau (Benešov) military base near Štěchovice was classified as the highest priority: “The Beneschau military training area is classified under No. ‘Prot. 42 Up c 1.’ From the last number of the number ‘1’ it can be seen that this GB-Bau-No. is the highest level in the relevant subject area, which the GB-Bau has to assign at all.” What work was conducted there?

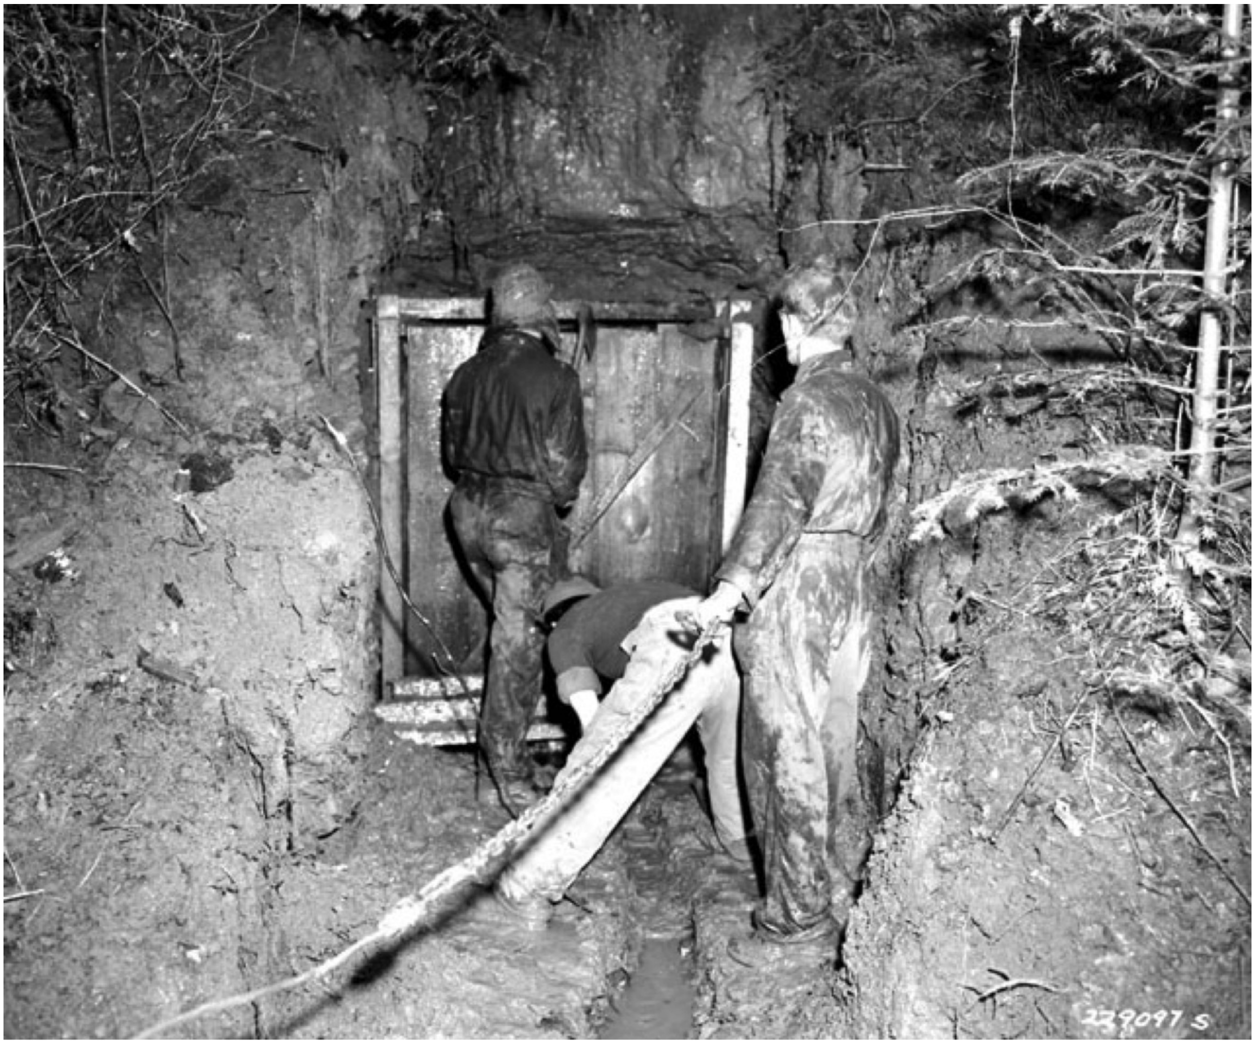

Figure D.312: In February 1946, a U.S. military team made an unannounced incursion deep into Czechoslovakia to recover important German papers buried at Štěchovice. The contents of most of the papers have never been publicly revealed [https://www.archives.gov/publications/prologue/2007/winter/stechovice.html]. This (in)famous incident was actually just one of many U.S. military incursions into Czechoslovakia in 1946 to collect mysterious cargo from multiple sites (pp. 3765–3772).

U.S. Apologizes For Army Raid On Czech Files

Nazi Documents Taken From Hillside Cache in Prague Area Will Be Returned

By Jay Reid

WASHINGTON, Feb. 23.—The State Department disclosed today that the United States has apologized to the government of Czechoslovakia for the action of an American armed detachment which blasted hidden Nazi documents from a hillside near Prague in a mysterious foray two weeks ago.

This government also ordered "immediate return" of the documents, of which photostatic copies were presumably made after they were obtained.

State Department sources refused to comment in detail on what information was found in the papers, or why they were snatched across the Czechoslovak border without a request to the government of that country for permission to examine them.

James F. Byrnes, Secretary of State, is understood to have communicated with the War Department to learn the circumstances of the seizure following a protest by Jan Masaryk, Foreign Minister of Czechoslovakia, to Ambassador Laurence A. Steinhardt, who made this government's apology today.

Official Version Quoted

The State Department then published the following official version of the incident:

"An American military detachment from the American occupation forces in Germany entered Czechoslovakia and proceeded to remove to the American zone in Germany a number of documents which weer found concealed in a hillside south of Prague. The detachment sought thees documents because they were informed that the documents would throw light upon the pre-war plans of Hitler, and give information as to the conduct of the war by the Nazi government.

"Although this American detachment entered Czechoslovakia with passes issued by the appropriate Czechoslovakian liaison officer, this expedition had not been given approval by the Czechoslovak government, which has protested this action.

"The American government has expressed its deep regret to President Benes for this incident and has ordered an immediate return of the documents to the Czechoslovak government."

The expedition took with it six or seven motor trucks, according to officials who said they presumed the search was ordered immediately after intelligence officers had been "tipped off" on the location of certain significant papers.

Benes Files Included

Reports from Prague stated that official and personal files of President Benes turned up among them, as well as records of the Nazi ruler of Bohemia-Moravia during German occupation.

Accounts published by the Czechoslovak official news agency asserted that an American "gang" had kept Czechoslovak civilians at a distance during a two-day effort to smash a wall which barred their way to a cavern near Stechovice. A Czech official was said to have been fired upon by an American when he approached the scene.

The Czech reports stated that three Americans, including a captain, were arrested, but that the rest of the party of thirteen had departed toward Germany with more than thirty boxes of documents taken from the cavern.

Speculation in Washington today ascribed considerable importance to the papers in view of the strong-arm methods employed to obtain them from within a neutral and formerly Allied country in peace time.

Opis

Úřední záznam.

Dne 14.II.1946 bylo zadrženo v Chebu /Wies/ americké auto s americkou vojenskou posádkou. Orgány OBZ vyžádali si zprávu z HSOBZ , zda smí auto propustiti na druhou stranu.

Poněvadž se jednalo o náklad porculánu, k jehož vývozu z ČSR neměli Američané povolení a poněvadž byla zde i možnost, že pod porcelánem mohly býti ukryté hledané dokumenty, nařídila HSOBZ složení nákladu a prohlídku obsahu.

Proti tomu se ostře ohradil vrchní finanční respicient Hanzlík , výrokem : "Nějaký oficír ze štábu MNO nám do toho nebude mluvit!", a auto přes zákaz i s nákladem propustil přes hranice.

Ježto náklad zásahem vrchního respicienta Hanzlíka bez prohlídky byl převezen přes hranice ČSR, je možné, že právě touto cestou dostala se část hledaného písemného materiálu do americké zony.

Dne 14.II.1946 v 15.00 hodin umožnil přejezd amerického auta údajně od UNNRy, z Oldřichova, okres Liberec, přes hranice ČSR št. strážm. SNB Kasal z Hrádku nad Nisou, který posádce auta vyjednal přejezd s Poláky v Oldřichově.

Totéž auto pokusilo se přejeti hranice u Habartic, okres Frýdlant a po nezdaru u Hartavy nedaleko Hrádku nad Nisou.

Official record.

On 14 February 1946, an American car with an American military crew was intercepted in Cheb. OBZ [Defense Intelligence Agency] authorities requested a report from HSOBZ [Main Administration of Defense Intelligence Agency] as to whether the car could be released to the other side.

Since it was a cargo of porcelain, which the Americans had no permission to export from Czechoslovakia, and since there was also the possibility that the wanted documents might be hidden under the porcelain, HSOBZ ordered the cargo to be gathered together and the contents to be searched.

The chief financial officer Hanzlik strongly objected to this, saying: "Some officer from the MNO staff will not interfere with us!" and despite the ban, he let the car and its cargo cross the border.

Since the cargo was transported across the Czechoslovak border without inspection by the intervention of chief financial officer Hanzlik, it is possible that it was through this route that some of the wanted written material reached the American zone.

On 14 February 1946, an American car, allegedly from the UNNRy in Oldřichov, Liberec district, was allowed to cross the border of Czechoslovakia by staff guard Kasal from Hrádek nad Nisou, who negotiated the crossing with the Poles in Oldřichov.

The same car tried to cross the border at Habartice, Frýdlant district, and after failure at Hartava near Hrádek nad Nisou.

[This document reports:

- An American military vehicle with an unknown cargo (concealed in or under porcelain) left Czechoslovakia for Germany at Cheb (due west of Prague).
- An American military vehicle with an unknown cargo left Czechoslovakia for Poland near Liberec (northeast of Prague), after trying unsuccessfully to leave Czechoslovakia at two other border checkpoints in that general area. The vehicle probably just cut across the extreme southwestern corner of Poland before returning to Germany.

These two U.S. military incursions were in addition to those at Štěchovice (pp. 3761–3763), Halámky-Rapšach (p. 3765), Prague-Vokovice to Karlovy Vary (p. 3768), Prague area (p. 3769), and apparently many others (p. 3772).

What exactly triggered all of these U.S. incursions into Czechoslovakia? Perhaps recently obtained information from interrogations, or fears that Czech or Soviet officials were about to seize or block access to certain sites or materials?

What did all of these U.S. incursions into Czechoslovakia retrieve?

Where are all of the retrieved materials and U.S. records about these incursions now?]

Loco Personal for Dean from Shuler signed Groves

Mr P. C. Keith will be in Czechoslovakia from approximately 15 September to 28 September. The name of the Military Attaché at Prague, Colonel Egmont F. Koenig, has been given to Keith. It is important that Koenig be notified of visit of Keith into Czechoslovakia so that Koenig may extend to him every courtesy possible should the occasion arise.

Wire Koenig immediately in Prague—Top Secret-priority—as follows and sign name of Dean: Mr P. C. Keith, President of U.S. Industrial Corporation, will be in Czechoslovakia on September 15th and may contact you personally. Important that every courtesy possible be shown him if occasion arises.

End

ORIGINATOR: Gen Groves

[Percival C. Keith, a chemical engineering graduate from MIT, was the chief designer and engineer of the Oak Ridge K-25 gaseous diffusion uranium enrichment facility. See for example:

https://www.nytimes.com/1976/07/12/archives/percival-c-keith-scientist-75-dies-worked-on-abomb-project-and-in.html

https://www.nae.edu/30698/Mr-Percival-C-Keith-Jr

https://ahf.nuclearmuseum.org/ahf/profile/percival-dobie-keith/

In September 1946, Leslie Groves sent Keith on a two-week Top Secret mission to Czechoslovakia. Groves also ordered Colonel Egmont Koenig (pp. 5541–5544) at the U.S. embassy in Prague to do anything possible to bail out Keith if he ran into trouble during his visit ("Important that every courtesy possible be shown him if occasion arises"). As the designer of Oak Ridge, Keith would have been an invaluable prize to the Czechs or Soviets if he had been captured.

Since this mission was ordered by Groves and led by Keith, it must have focused on nuclear issues. Since the mission was Top Secret and Keith was sent despite the great risk if he had been captured, it must have been extremely high priority.

The logical target for such a mission would be former wartime German nuclear resources in Czechoslovakia that were now being used or in danger of being used by Czech/Soviet forces. There was considerable wartime German and postwar Soviet mining of uranium ore in Czechoslovakia, but that was already being addressed by other U.S./U.K. investigators with much more expertise with mining and/or espionage and much less risk if captured than Keith (e.g., pp. 4980–4984).

It seems as if the only target that would require the specific expertise of Keith and justify the great risk of sending him would be a former German uranium enrichment facility in Czechoslovakia. Was Keith's mission to help inspect/remove/destroy key components at an enrichment facility? Can anyone locate more archival documents regarding the information that prompted Keith's mission, what he did during his mission, and the resulting reports or other impacts after his mission?

For examples of similar incidents, see pp. 3761–3769, 3772, 4613–4615, 4853, 4980–4981, 5050.]

Předmět : Pohraniční přechody-závady při výkonu prohlídek.

Podle zprávy podané dustojníkem MNO, který se zúčastnil oficiálního rozhovoru s americkým velvyslancem Steinhardtem a US voj. attachém plk. Koenigem, ze dne 12.11.1946, stěžovali si tito amer. představitelé na nedostatečné celní a pasové prohlídky na čsl. pohraničních přechodech.

Velvyslanec Steinhardt tvrdil, že příslušní amer. činitelé velmi ostře zakročují proti pokusům o pašovaní a pokusům o černý obchod. jestliže jsou zúčastněni amer. občané, nebo příslušníci US armády. Poukazoval na případy, kdy do Prahy přijíždějí americka vozidla s falešnými čísly, bez čísel, šoferi bez dukomentu a pod., což jest dusledkem nesprávné čs. pohraniční kontroly. Zároveň projevil podiv nad tím, že čs. úřady neponikají přísnějších opatření proti tomu stavu i když sám chape, že jde o poválečné poměry, které nelze odstraniti najednou.

Sám by podobné opatření podporoval a jak uvedl, požádal již čs. kontrolní orgány na letišti v Ruzýni a na pohraničních přechodech, aby přísněji postupovali při prohlídkách a nečinili rozdílu ani kdyby se jednalo o jeho osobního šoféra, či pilota.

K černému obchodu s cigaretami uvedl : "Já jdu proti černému obchodu s americkými cigaretami velmi ostře, avšak bez Vaší pomoci to nevykořeníme".

Ministerstvo vnitra na tuto zpravu upozorňuje a přikazuje, aby vytčené nedostatky provedením vhodných opatření byly odstraněny.

Rybín Jaroslav
nar. 25.4.1923
K Závěrce 2752/34
Praha 5

Praha dne 3. června 1986

Vážený soudruhu generální tajemníku a presidente ČSSR.

Předem prosím, abyste přijal odemne srdečný soudružský pozdrav a prominul mi, že se snažím Vás připravit o cenný čas, kterého jistě při své odpovědné funkci nemáte nikdy nazbyt.

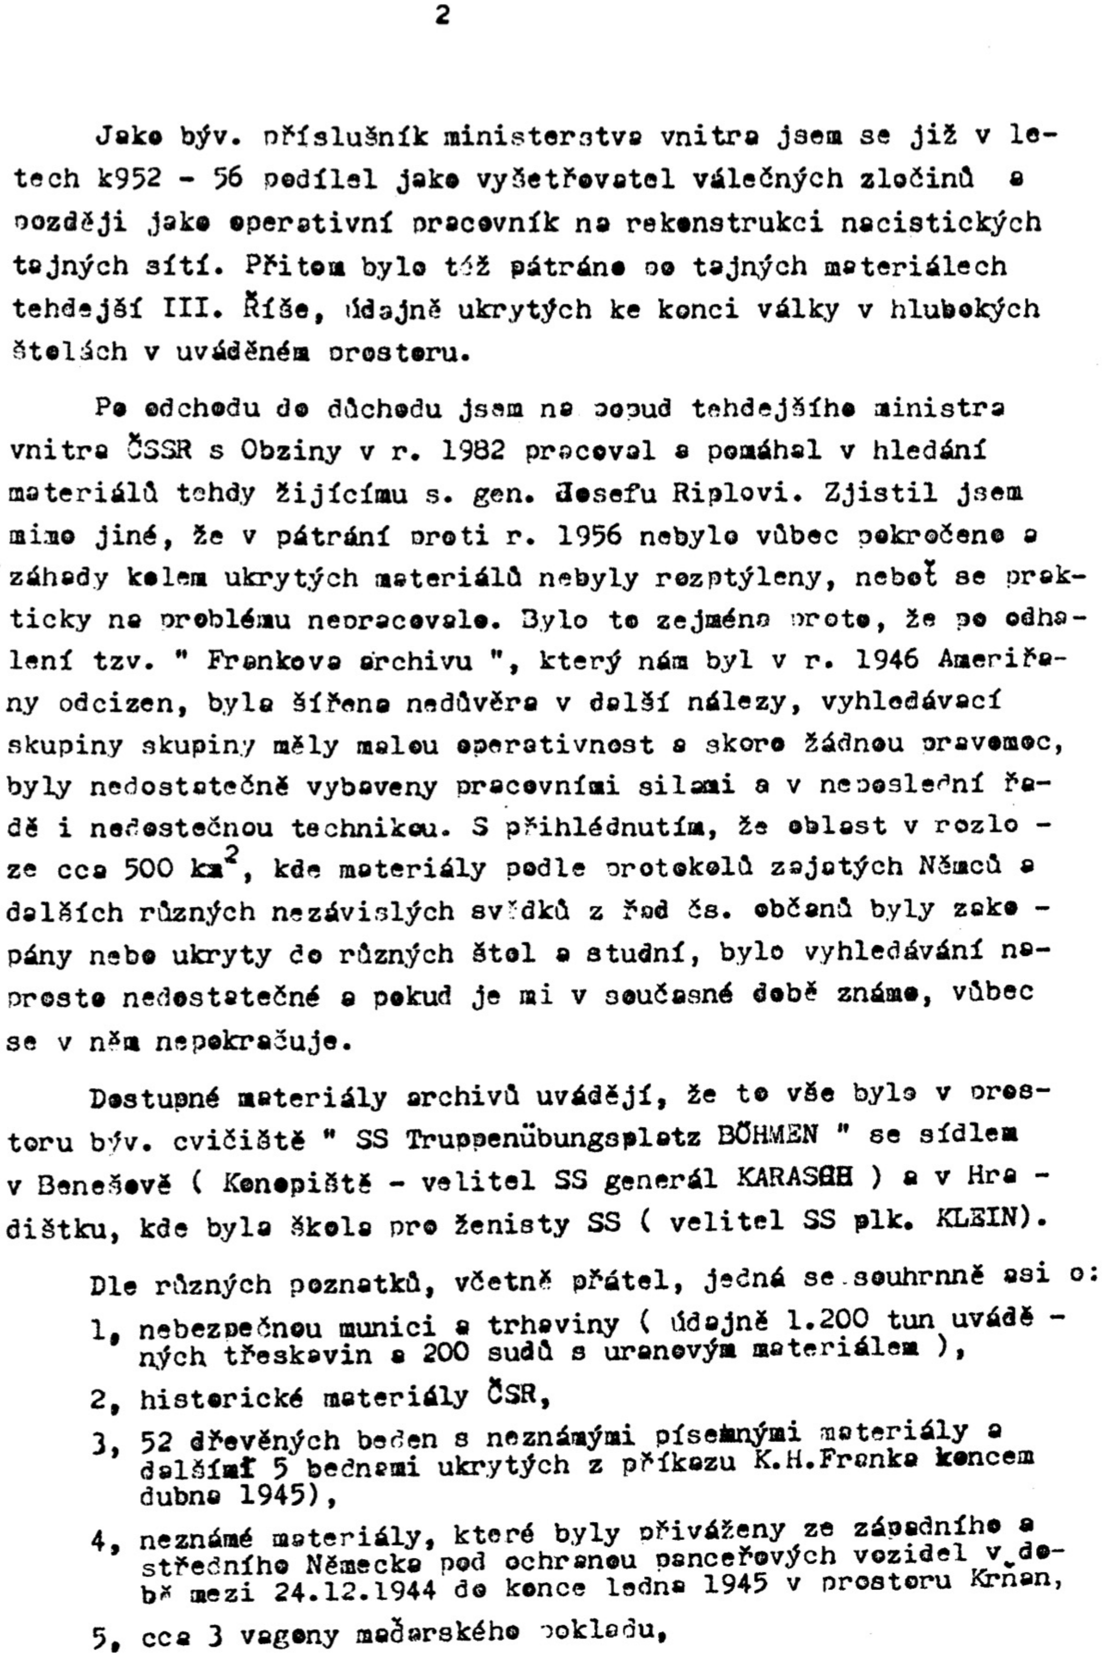
Napsat Vám dopis mne nutí mé svědomí, které inspirovaly události kolem havarie atomové elektrárny v Černobylu. Nikdy jsem si předtím neuvědomoval, že i v " celku nevelká " havarie může mít tak veliké následky s tak namáhavými a nebezpečnými úkoly s jejich odstraňováním.

Píši proto, že i my máme nedaleko Prahy docela ještě strašnější hrozbu, - dědictví po německé okupaci. Jedná se o sklad cca 1.200 tun velmi brisantní trhaviny spolu s cca 200 sudy obohaceného uranu, které Němci ukryli před postupující Sovětskou armádou v prostoru Štěchovice, Hradištko, Závist, Krňany, Benešov až Sedlčany.

V poslední době se hodně psalo o tektonických poruchách, které z části zasahovaly i Středočeský kraj. Jímá mne hrůza při pomyšlení, že v souhrnu náhod by došlo tektonickým pohybem půdy ke vznícení trhavin, které by při výbuchu a vzniklým žárem roztavily sudy s uranem. Tím by z podkritických hodnot jednotlivých sudů najednou vznikla silná nadkritická hodnota štěpného materiálu a výbuch by se stal výbuchem atomové pumy, která by ohrozila nejen hlavní město Prahu, ale ochromila by možná celé Čechy i sousední státy.

Tyto poznatky nejsou jen mojí fantasií, ale jsou co do ukrytí materiálu doloženy poznatky v archivu ministerstva vnitra ČSSR.

Figure D.322: 3 June 1986 letter from Rybín Jaroslav [Czech National Archive, courtesy of Adam Kretschmer].



2

Jako býv. příslušník ministerstva vnitra jsem se již v letech k952 - 56 podílel jako vyšetřovatel válečných zločinů a později jako operativní pracovník na rekonstrukci nacistických tajných sítí. Přitom bylo též pátráno po tajných materiálech tehdejší III. Říše, údajně ukrytých ke konci války v hlubokých štolách v uváděném prostoru.

Po odchodu do důchodu jsem na popud tehdejšího ministra vnitra ČSSR s Obziny v r. 1982 pracoval a pomáhal v hledání materiálů tehdy žijícímu s. gen. Josefu Riplovi. Zjistil jsem mimo jiné, že v pátrání proti r. 1956 nebylo vůbec pokročeno a záhady kolem ukrytých materiálů nebyly rozptýleny, neboť se prakticky na problému nepracovalo. Bylo to zejména proto, že po odhalení tzv. " Frankova archivu ", který nám byl v r. 1946 Američany odcizen, byla šířena nedůvěra v další nálezy, vyhledávací skupiny skupiny měly malou operativnost a skoro žádnou pravomoc, byly nedostatečně vybaveny pracovními silami a v neposlední řadě i nedostečnou technikou. S přihlédnutím, že oblast v rozloze cca 500 km^2, kde materiály podle protokolů zajatých Němců a dalších různých nezávislých svědků z řad čs. občanů byly zakopány nebo ukryty do různých štol a studní, bylo vyhledávání naprosto nedostatečné a pokud je mi v současné době známo, vůbec se v něm nepokračuje.

Dostupné materiály archivů uvádějí, že to vše bylo v prostoru býv. cvičiště " SS Truppenübungsplatz BÖHMEN " se sídlem v Benešově (Konopiště - velitel SS generál KARASCH) a v Hradištku, kde byla škola pro ženisty SS (velitel SS plk. KLEIN).

Dle různých poznatků, včetně přátel, jedná se souhrnně asi o:

1, nebezpečnou munici a trhaviny (údajně 1.200 tun uváděných třeskavin a 200 sudů s uranovým materiálem),

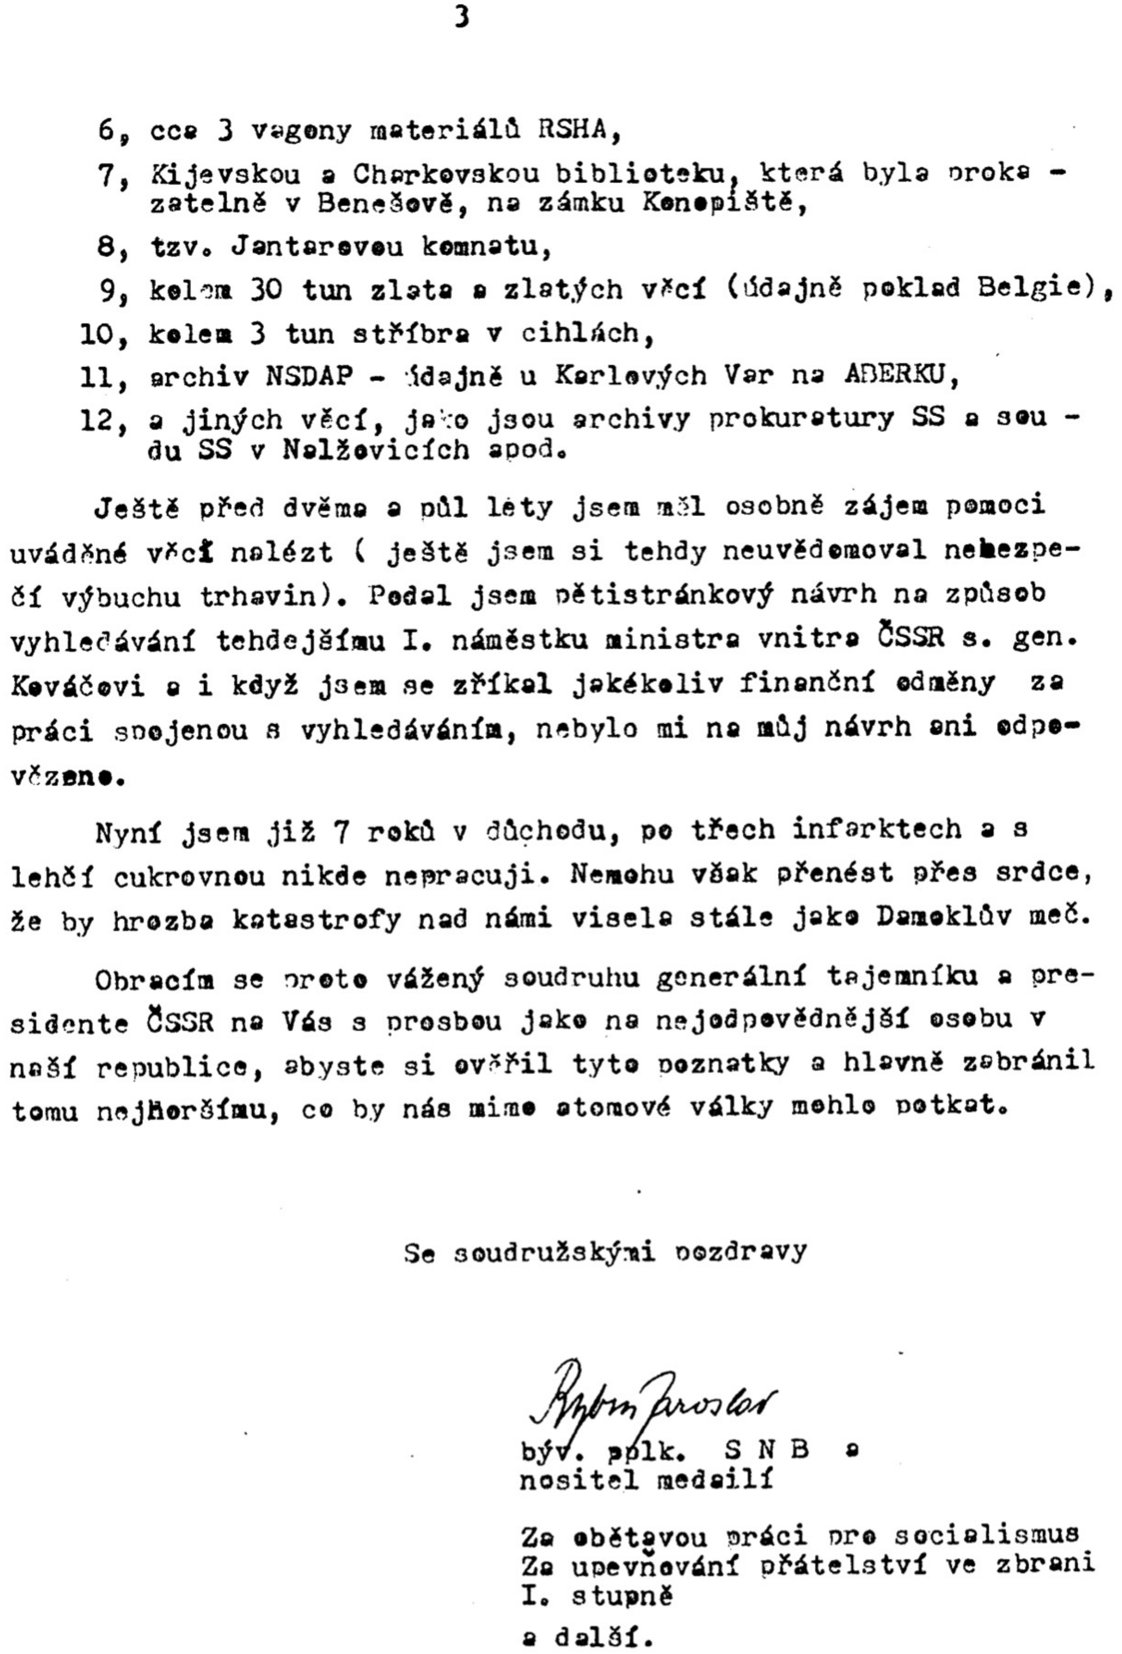
2, historické materiály ČSR,

3, 52 dřevěných beden s neznámými písemnými materiály a dalšími 5 bednami ukrytých z příkazu K.H.Franka koncem dubna 1945),

4, neznámé materiály, které byly přiváženy ze západního a středního Německa pod ochranou pancéřových vozidel v době mezi 24.12.1944 do konce ledna 1945 v prostoru Krňan,

5, cca 3 vagony maďarského pokladu,

Figure D.323: 3 June 1986 letter from Rybín Jaroslav [Czech National Archive, courtesy of Adam Kretschmer].



3

6, cca 3 vagony materiálů RSHA,

7, Kijevskou a Charkovskou biblioteku, která byla prokazatelně v Benešově, na zámku Konopiště,

8, tzv. Jantarovou komnatu,

9, kolem 30 tun zlata a zlatých věcí (údajně poklad Belgie),

10, kolem 3 tun stříbra v cihlách,

11, archiv NSDAP - údajně u Karlových Var na ABERKU,

12, a jiných věcí, jako jsou archivy prokuratury SS a soudu SS v Nalžovicích apod.

Ještě před dvěma a půl lety jsem měl osobně zájem pomoci uváděné věci nalézt (ještě jsem si tehdy neuvědomoval nebezpečí výbuchu trhavin). Podal jsem pětistránkový návrh na způsob vyhledávání tehdejšímu I. náměstku ministra vnitra ČSSR s. gen. Kováčovi a i když jsem se zříkal jakékoliv finanční odměny za práci spojenou s vyhledáváním, nebylo mi na můj návrh ani odpovězeno.

Nyní jsem již 7 roků v důchodu, po třech infarktech a s lehčí cukrovkou nikde nepracuji. Nemohu však přenést přes srdce, že by hrozba katastrofy nad námi visela stále jako Damoklův meč.

Obracím se proto vážený soudruhu generální tajemníku a presidente ČSSR na Vás s prosbou jako na nejodpovědnější osobu v naší republice, abyste si ověřil tyto poznatky a hlavně zabránil tomu nejhoršímu, co by nás mimo atomové války mohlo potkat.

Se soudružskými pozdravy

Rybín Jaroslav

Figure D.324: 3 June 1986 letter from Rybín Jaroslav [Czech National Archive, courtesy of Adam Kretschmer].

Rybín Jaroslav
25.4.1923
K Závěrce 2752/34
Prague 5

Prague 3 June 1986

Dear comrade Secretary General and President of the ČSSR [Czecho-Slovak Socialist Republic],

First of all please accept my comradely greeting, and excuse me that I deprive you of precious time, which you surely do not have much to spare.

I am compelled to write you this letter spurred by the events around the Chernobyl nuclear accident. I had not realized before that even "not really major" accidents could have such serious consequences requiring difficult and dangerous clean-up operations.

I am writing you because there is near Prague an even more dangerous threat that we inherited from the German occupation. There is a deposit of approximately 1200 tons of high explosives together with approximately 200 barrels of enriched uranium that were hidden in the area of Štěchovice, Hradišt'ko, Závist, Krňany, Benešov, and Sedlčany, by the German forces retreating before the victorious Soviet Army.

There have been news recently about tectonic disturbances affecting partially Central Bohemia District. I am terrified to think what could happen if tectonic movements would by coincidence lead to ignition of the explosives and the subsequent blast that would melt the barrels with the uranium. This would lead from subcritical mass contained in each of the barrels to the fusion of critical mass and the explosion would thus in effect be the explosion of an atomic bomb that would endanger not only the capital city of Prague, but most probably the whole Bohemia and neighbouring states.

These findings are not mere fantasy of mine, but are based on the findings in the Archive of the Interior Ministry of the ČSSR.

As a former officer of the Interior Ministry I was working in 1952–56 as war crimes investigator and later as operational officer on the reconstruction of the Nazi secret services activities. One of the things that were investigated were secret materials of the Third Reich apparently hidden by the end of the war in deep tunnels in the area I mentioned above.

After my retirement on the orders of the then Minister of the Interior comrade Obzina I was working and helping comrade General Josef Ripl with locating those materials. I have found out, among other, that the search did not advance compared to 1956 and that the secrets surrounding hidden materials were not solved because there was practically no activity in this regard. It was primarily because after the affair with the so called "Frank's Archive" there was suspicion regarding other findings, search parties had very low operatibility and almost no authority, they were understaffed and also underequipped. If we take into consideration the fact that the area in question, where according to the interrogation protocols of captured Germans and according to testimonials of various Czechoslovak witnesses these materials were hidden into various tunnels and water wells, has approximately 500 km^2, the search efforts were totally inadequate and as far as I am aware no further efforts are being made.

The accessible archival materials attest that the area in question is former military training ground "SS Truppenübungsplatz BÖHMEN" with the command in Benešov (Konopiště – commander SS General KARASCH) and in Hradištko where a school for SS sappers was located (commander SS Colonel KLEIN).

According to various sources, including those from my acquaintances, we are dealing with:

1. Dangerous ammunition and explosives (allegedly including above mentioned 1200 tons high explosives and 200 barrels of uranium).
2. Historical materials belonging to Č[S]SR.
3. 52 wooden boxes with unidentified written materials and other 5 boxes hidden by the order of K.H. Frank at the end of April 1945.
4. Unidentified materials that were transported from western and central Germany under the protection of armored vehicles between 24.12.1944–end of January 1945 to the area of Krňany.
5. Approximately 3 wagons of Hungarian treasure.
6. 3 wagons of RSHA materials.
7. Kiev and Kharkiv libraries that were arguably located in Benešov, at Konopiště Chateau.
8. So called Amber Room [Bernsteinzimmer].
9. Around 30 tons of gold and golden treasure (presumably incl. Belgian treasure).
10. Around 3 tons of silver bars.
11. Archive of the NSDAP, presumably near Karlovy Vary at ABERK.
12. Miscellanea, including archives of the SS Prosecution Office and Tribunal at Nelžovice etc.

Two years ago I was personally disposed to assist in locating the above mentioned (back then I did not yet realize the danger posed by the explosives). I submitted a 5-page draft regarding means of locating the stuff mentioned above to the then First Deputy Minister of Interior, comrade General Kováč, and even though I explicitly renounced any financial recompense connected with the search, I never even received an answer back.

I have been 7 years in retirement, and after three heart attacks and light diabetes I am not working anywhere. I can not ignore though the danger of the catastrophe looming above us like the Sword of Damocles.

I therefore turn to you, dear comrade Secretary General and President of the ČSSR as the most responsible person in our republic, to confirm these findings and especially to prevent the worse that can happen to us, save for atomic war.

With comradely greetings,

Rybín Jaroslav
SNB [National Security Corps] Lieutenant Colonel (ret.)
Awardee of the medals: For Selfless Work for Socialism,
For Securing Friendship in Arms, First Class, and others.

[If this information is correct, "approximately 200 barrels of enriched uranium" would be the product of an industrial-scale nuclear weapons program, not small-scale laboratory experiments. And that is only the enriched uranium that this particular person knew about in this particular location. How much enriched uranium had been produced throughout German-controlled territory by the end of the war, to what degrees was it enriched, and by which enrichment methods?]

K Závěrce 2752/34
Praha 5

Praha dne 1. září 1986

Vážený soudruhu generální tajemníku ÚV KSČ a presidente ČSSR.

Dovlte mi, abych se předem omluvil, že znovu obtěžuji problémem, který jsem Vám již sdělil dopisem ze dne 3.6.1986.

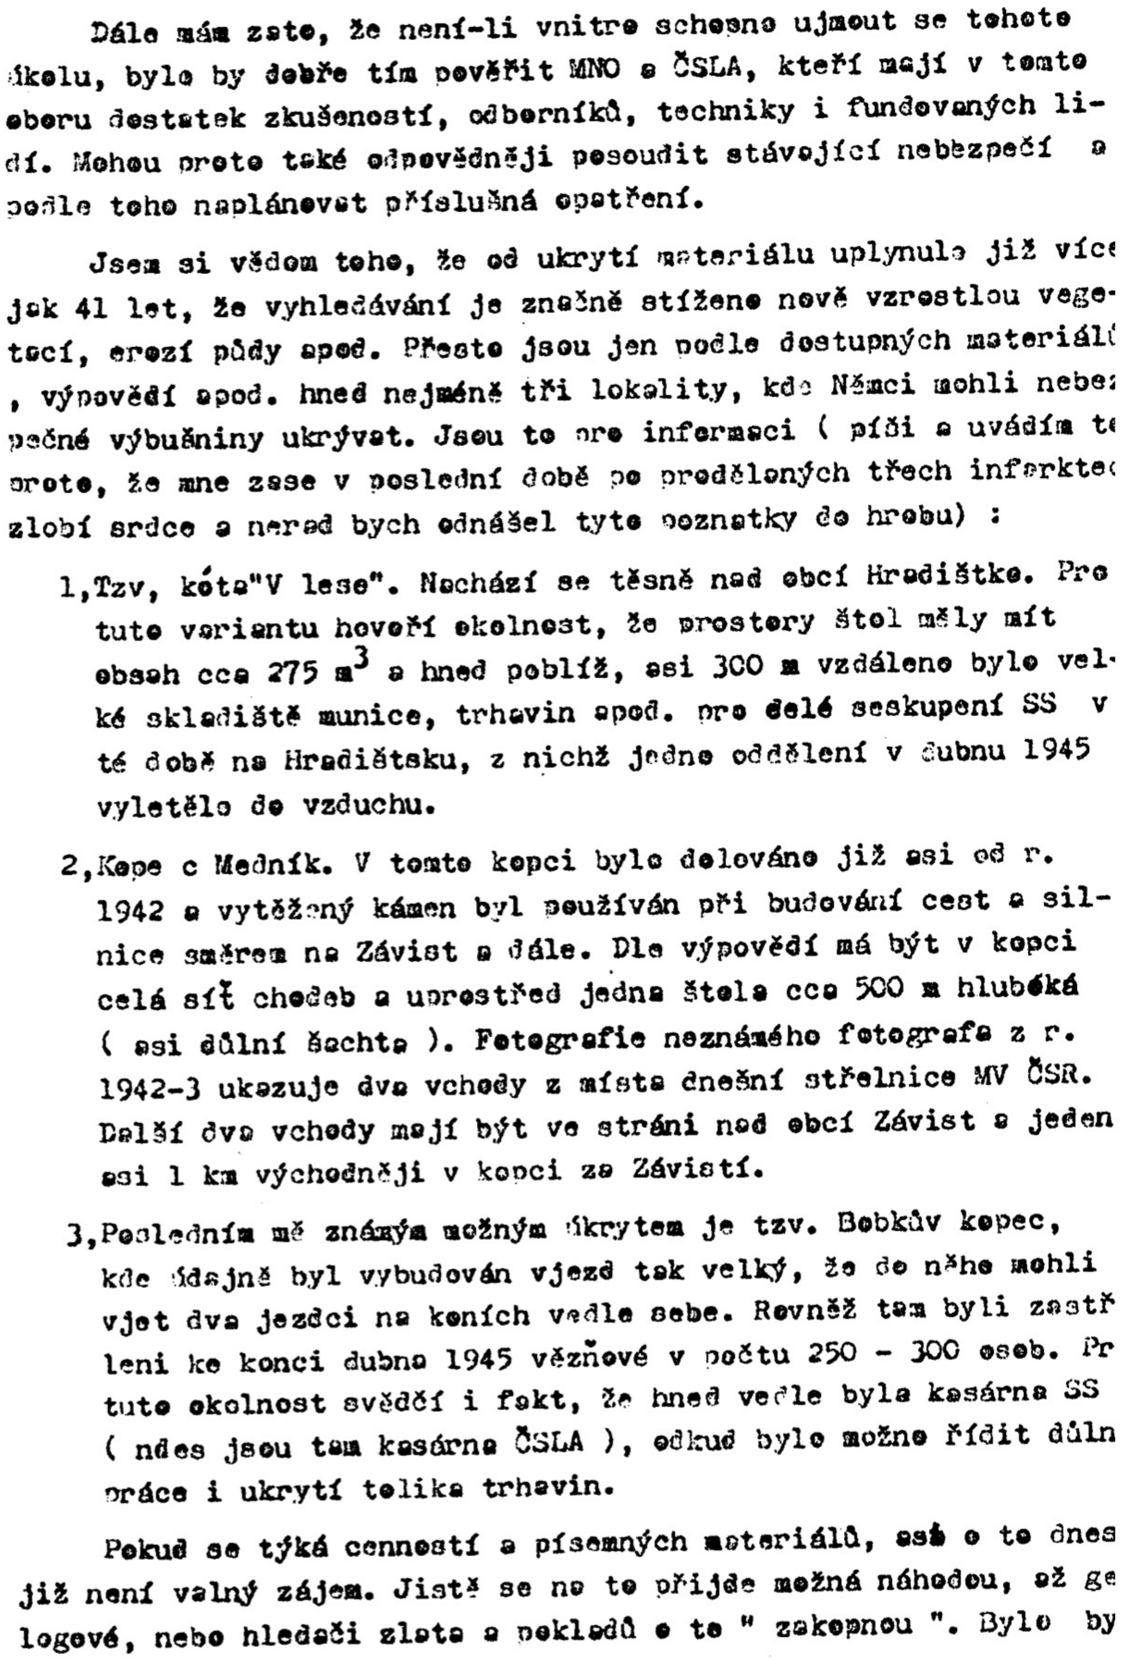
V červnu tr. jsem byl navštíven dvěma pracovníky Federální správy VB (mjr. Urban Jan a spol.). Pochopil jsem z pohovoru, že jde o upřesňování poznatků a názorů, které jsem Vám zaslal. Po vysvětlení některých bodů jsem jim ještě zapůjčil i dvě kopie dopisů, které jsem napsal v minulosti a které údajně na MV ČSSR nenašli (býv. ministru vnitra ČSSR s. Obzinovi a býv. 1. náměstku MV ČSSR s. gen. Kovačovi, které mě dosud nebyly vráceny). Nabyl jsem z tohoto jednání dojem, že pracovníci FS VB nechápou veliké nebezpečí, které zde je (třebas jen pouhý únik radioaktivity v případě i náhodného poškození kontejneru apod.) a zaměřují se jen na problém hledání uloupených cenností, nebo písemných dokumentů tzv. III. Říše.

Nyní po návratu z delšího letního pobytu v Lučenci jsem navštívil lokality býv. cvičiště SS na Hradištsku. Zjistil jsem, že podezřelá místa úlože ukrytých nebezpečných trhavin a uranu nikdo neprověřuje a nebezpečí pro okolí stále přetrvává.

Z pohovoru s pracovníky FS VB a vlastním ohledáním jsem nabyl přesvědčení, že Federální ministerstvo vnitra a jeho složky podceňují nebezpečí, nebo na druhé straně nejsou vůbec schopni zabránit možné katastrofě.

Proto jako komunista se znovu obracím na Vás, abyste posoudil nebo nechal prověřit stav šetření. Jako býv. konzultant ministra vnitra ČSSR mám zato, že není těžké ani organizačně nemožné urychleně zahájit vyhledávání a zneškodnění trhavin, jakož i bezpečně zajistit výskyt uranu, jak jsem již uváděl v prvním dopise.

Figure D.325: 1 September 1986 letter from Rybín Jaroslav [Czech National Archive, courtesy of Adam Kretschmer].



Dále mám zato, že není-li vnitro schopno ujmout se tohoto úkolu, bylo by dobře tím pověřit MNO a ČSLA, kteří mají v tomto oboru dostatek zkušeností, odborníků, techniky i fundovaných lidí. Mohou proto také odpovědněji posoudit stávající nebezpečí a podle toho naplánovat příslušná opatření.

Jsem si vědom toho, že od ukrytí materiálu uplynulo již více jak 41 let, že vyhledávání je značně stíženo nově vzrostlou vegetací, erozí půdy apod. Přesto jsou jen podle dostupných materiálů , výpovědí apod. hned nejméně tři lokality, kde Němci mohli nebezpečné výbušniny ukrývat. Jsou to pro informaci (píši a uvádím to proto, že mne zase v poslední době po prodělaných třech infarktec zlobí srdce a nerad bych odnášel tyto poznatky do hrobu) :

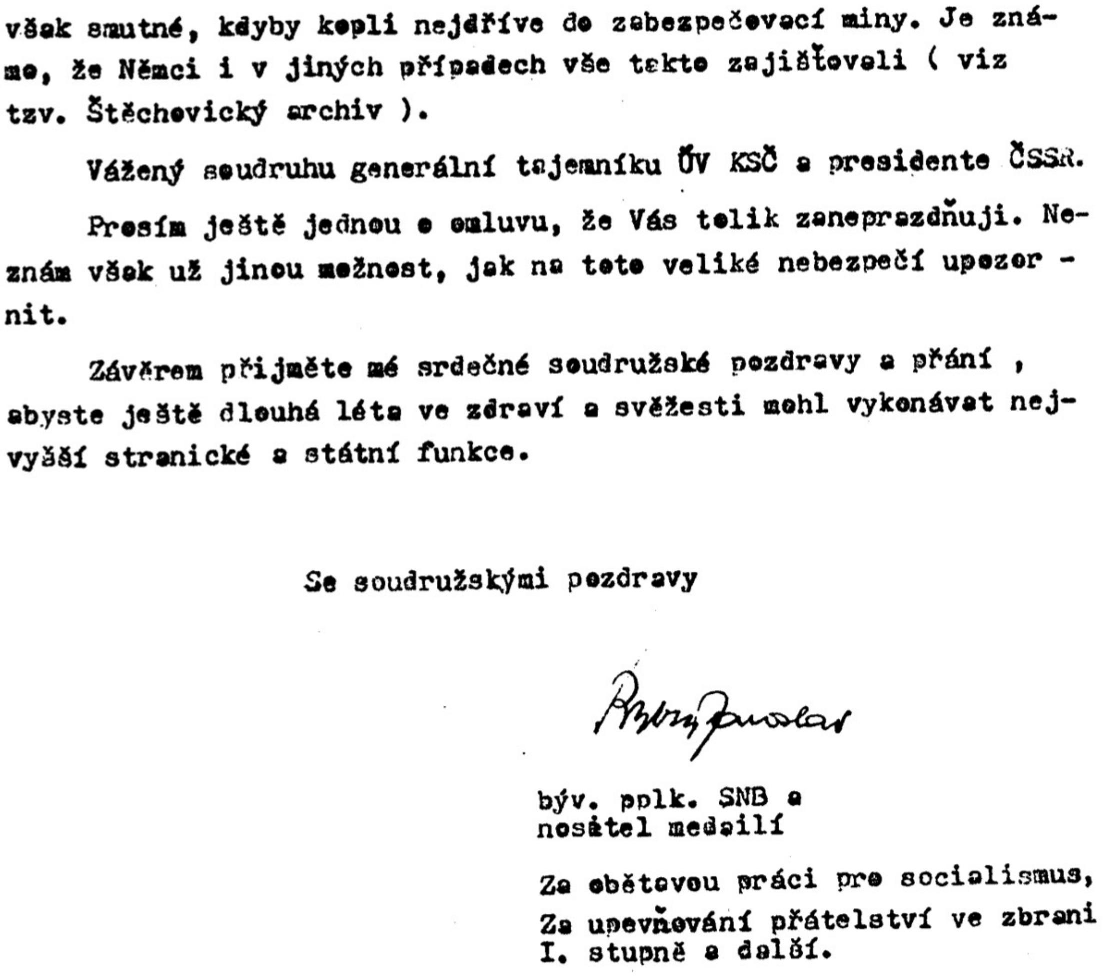
1,Tzv, kóta"V lese". Nachází se těsně nad obcí Hradištko. Pro tuto variantu hovoří okolnost, že prostory štol měly mít obsah cca 275 m^3 a hned poblíž, asi 300 m vzdáleno bylo veliké skladiště munice, trhavin apod. pro celé seskupení SS v té době na Hradištsku, z nichž jedno oddělení v dubnu 1945 vyletělo do vzduchu.

2,Kopec Medník. V tomto kopci bylo dolováno již asi od r. 1942 a vytěžený kámen byl používán při budování cest a silnice směrem na Závist a dále. Dle výpovědí má být v kopci celá síť chodeb a uprostřed jedna štola cca 500 m hluboká (asi důlní šachta). Fotografie neznámého fotografa z r. 1942-3 ukazuje dva vchody z místa dnešní střelnice MV ČSR. Další dva vchody mají být ve stráni nad obcí Závist a jeden asi 1 km východněji v kopci za Závistí.

3,Posledním mě známým možným úkrytem je tzv. Bobkův kopec, kde údajně byl vybudován vjezd tak velký, že do něho mohli vjet dva jezdci na koních vedle sebe. Rovněž tam byli zastřleni ke konci dubna 1945 vězňové v počtu 250 - 300 osob. Pr tuto okolnost svědčí i fakt, že hned vedle byla kasárna SS (nyní jsou tam kasárna ČSLA), odkud bylo možno řídit důln práce i ukrytí tolika trhavin.

Pokud se týká cenností a písemných materiálů, asi o to dnes již není valný zájem. Jistě se na to přijde možná náhodou, až gelogové, nebo hledači zlata a pokladů o to " zakopnou ". Bylo by

Figure D.326: 1 September 1986 letter from Rybín Jaroslav [Czech National Archive, courtesy of Adam Kretschmer].



však smutné, kdyby kopli nejdříve do zabezpečovací miny. Je známo, že Němci i v jiných případech vše takto zajišťovali (viz tzv. Štěchovický archiv).

Vážený soudruhu generální tajemníku ÚV KSČ a presidente ČSSR.

Prosím ještě jednou o omluvu, že Vás tolik zaneprazdňuji. Neznám však už jinou možnost, jak na toto veliké nebezpečí upozornit.

Závěrem přijměte mé srdečné soudružské pozdravy a přání , abyste ještě dlouhá léta ve zdraví a svěžesti mohl vykonávat nejvyšší stranické a státní funkce.

Se soudružskými pozdravy

Rybín Jaroslav

býv. pplk. SNB a

Rybín Jaroslav
25.4.1923
K Závěrce 2752/34
Praha 5

Praha 1 September 1986

Dear comrade Secretary General and President of the ČSSR,

First of all, please accept my apology for contacting you again regarding the matters I presented in my letter to you of 3 June 1986.

In June of this year I was visited by two officers of Federal Service of VB (Public Security /Police/) (Major Jan Urban and a colleague). I understood from the interview that they visited me to clarify some points regarding the matters I wrote you about. After providing clarification I gave them two copies of the letter that I wrote previously to the then Minister of the Interior comrade Obzina and to the then First Deputy Minister of the Interior comrade General Kovač. No copy of the letter was ever returned to me, and even so the Ministry of Interior claims they have been unable to find them in their archive. I got the impression from the interview that the VB Federal Service officers don't understand the magnitude of the danger present (even including a mere radioactive leak in case of accidental damage to a barrel etc.) and that they focused only on issues of finding the lost valuables or written documents of the Third Reich.

After I had returned from a longer summer stay at Lučenec, I visited the area of the former SS training grounds at Hradištsko. I found out that suspected places where dangerous explosives and the uranium may be located were not being searched and thus the danger for local environment persists.

From the interview with the officers of the VB Federal Service and by checking personally the locality, I got the impression that the Federal Ministry of the Interior and its departments underestimate the danger or perhaps they don't even have the means to avert a possible catastrophe.

Therefore I turn to you as a communist to have this reviewed and examined. As a former specialist of the Ministry of the Interior of the ČSSR I hold that it is neither hard nor impossible from an organizational point of view to start locating and disarming the explosives, as well as safely deal with the uranium, that I mentioned in my first letter.

It is my belief that if the Interior Ministry is not able to deal with this task, it could be delegated to the Defence Ministry and the ČSLA (Army) that have in this regard lot of experiences, specialists, technical means and personal capabilities. They can best evaluate the present danger and plan accordingly how to deal with it.

I am aware that 41 years have passed since the materials were hidden, and that the search is more difficult due to grown vegetation, soil erosion, etc. Nonetheless, according to available evidence, testimonies, etc., there are at least three possible locations where the Germans could have hidden dangerous explosives. These are for your information (I write it here since after three heart attacks my heart is starting to act up again and I don't want to take my knowledge with me to the grave) the following locations:

1. The so called “V lese” spot. It is located directly above Hradištko. The factors favoring this location are that the volume of the tunnels is supposed to be approximately 275m^3 and that nearby, around 300 m away, there was an ammunition and explosives depot for the SS unit stationed at Hradištko, a part of which exploded in April 1945.

2. The Medník hill spot. This hill was mined since 1942 and the mined stone was used to build communications to Závist and beyond. According to testimonies there is supposed to be a network of passages and one tunnel approximately 500 m deep (mining tunnel) located in the hill. Photos made by an unidentified photographer in 1942–43 show two entrances located at the area of a current shooting training ground of the Interior Ministry of the ČSSR. Another two entrances should be located in the hillside above Závist and one about 1 km east of Závist.

3. The last possible hiding place location known to me is so called Bobkův kopec hill spot, where allegedly an entrance was constructed of sufficient dimensions that two horse riders could enter riding side by side. It is also a place where around the end of April 1945 250–300 prisoners were shot. A factor favouring this location is that right next to it there were SS barracks (now ČSLA barracks) from where it was possible to direct the hiding of such an amount of explosives.

Regarding the valuables and written materials, these are not of such an interest today. They may be found by accident when geologists or treasure seekers would “trip over them” by accident.

It would be sad though if they would first trip over the safety explosives. It is well known that the Germans used to secure valuables in this way (see the so-called Štěchovice Archive).

Dear comrade Secretary General and President of the ČSSR, please accept once more my apology for keeping you busy. But I don’t know what else to do to point out this grave danger.

Finally, please accept my heartfelt comradely greetings and best wishes for you to serve in the highest Party and State capacities for many coming years full of health and vigor.

With comradely greetings,

Rybín Jaroslav

SNB (National Security Corps) Lieutenant Colonel (ret.)

1. Leverkusen [...]

2. Dubnica (Czechoslovakia) — This plant has been carefully studied by the Crossbow Committee in interpretation report #U17. It is an excellent factory for making anything. More specifically, the underground facilities, which include quite sizeable steam installations, would make possible the location of a plant of LTD [Liquid Thermal Diffusion, i.e. uranium enrichment], or similar style in fractional scale, at this site. The absence of visible handling facilities for large equipment, etc., is not conclusive, but it is a bit strange if this is really a normal factory for producing ordnance. No specific features except the steel and water facilities would imply a plant of special interest to us, but on the other hand, one cannot exclude that it is such a plant. Here I would like to keep watching this installation and would especially like to see the Crossbow report H(1)131, which was an earlier report on the same site.

3. Hechingen [...]

Subject: Evaluation of Air Photos.

To: Major Frank J. Smith, P. O. Box 2610, Washington, D. C.

1. Leverkusen - the PW report mentioning heavy concrete structures at this plant (Calvert - 29 January 1945) is an evident lead in our direction. Such structures imply either the operation of a 49 pile or a chemical operations plant for active material from such a pile. It does not seem likely that these operations, which are not on a heavy chemical scale, would be carried out in the crowded site at Leverkusen. I have looked over the whole plant and I do not find any such structures except for a line of dubious objects across the river which I have circled on prints #4009 and #4114. I would like to show these objects to one of the Interpretation Officers in the Pentagon. It is unlikely, however, that this is a tip to operations of our interests.

I note with enthusiasm in the latest coverage, a direct hit on the power house which edges the buildings number 31 through 36. This is made to order for us, since it is this area which represents the best enemy installation for the processing of fluorine compounds and, therefore, probably of hex. This area was closed tight in November 1944. If it is not too difficult for the operational crews, I should like to see another coverage of Leverkusen to examine repair on this particular area.

2. Dubnica (Czechoslovakia) -- This plant has been carefully studied by the Crossbow Committee in interpretation report #U17. It is an excellent factory for making anything. More specifically, the underground facilities, which include quite sizeable steam installations, would make possible the location of a plant of LTD, or similar style in fractional scale, at this site. The absence of visible handling facilities for large equipment, etc., is not conclusive, but is a bit strange if this is really a normal factory for producing ordnance. No specific features except the steel and water facilities would imply a plant of special interest to us, but on the other hand, one cannot exclude that it is such a plant. Here I would like to keep watching this installation and would especially like to see the Crossbow report H(1)131, which was an earlier report on the same site.

3. Hechingen - I received no text at all with these pictures, but I studied the pictures at length. There are very many remarkable features about this plant, which is in the stage of active construction. I do not know what this plant is doing. The very large pipe or pressure vessels visible everywhere indicate a chemical process involving handling large amounts of gas. The strip mining, or possibly just dirt moving, which is going on, the presence of many cranes and other elevated structure, the possible large concrete structure, which I have circled on the prints, do not combine to indicate conventional kind of operation. Taken with our information that this region is, in fact, a seat of special work on our Project, the pictures are of great interest. I do not believe that a 49 plant is being constructed here, but I would not at all be surprised if some sort of isotope separation in a gas phase is being contemplated on a rather small scale. There are no data to make this "yes" probable, and the plant may very well be for some other chemical purpose (rocket fuel, etc.), but it is a most unconventional kind of operation.

The quality of the photos leaves a great deal to be desired. I would strongly recommend improved coverage of this plant.

P. Morrison
P. Morrison

Figure D.328: Philip Morrison to Francis J. Smith. 17 February 1945. Subject: Evaluation of Air Photos [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)].

Known/Reported Sites Now in Denmark

[Many 1945–1948 newspaper articles alleged that there was some sort of German nuclear work on the Danish island of Bornholm during the war, and that Soviet forces occupying the island after the war removed material from that work:

> Clearing of Bornholm: Germans Who Refused to Surrender. *The Times* (London, 15 May 1945).
>
> Danes Seek Restoration of Communications. *The Times* (London, 18 May 1945).
>
> Russians Believed Near Atom Secret. *New York Times* (15 October 1945 p. 4).
>
> Russia Will Have Secret Soon. *News Chronicle* (15 October 1945 p. 1).
>
> Russia Confident on Bomb. *New York Times* (31 October 1945 p. 6).
>
> Atomic Energy May Be Behind Bornholm Mystery. *Sydney Morning Herald* (20 April 1946 p. 2).
>
> Rich Uranium Ore on Danish Island Russia Evacuated. *Spokane Daily Chronicle* (16 March 1948 p. 6).

With advanced rockets under development at Peenemünde East, advanced aircraft under development at Peenemünde West, biological weapons under development on Riems island, and apparent nuclear tests carried out in the vicinity of the Baltic coast, it would make sense for some of the nuclear development programs to be conducted on Bornholm or elsewhere in that general area. Highly secretive and potentially dangerous military research projects seem to have been deliberately clustered in this sparsely populated area around the Baltic coast, far from Allied forces in both directions at the time that work was begun. The following formerly secret Allied intelligence documents confirm that there were indeed nuclear materials and programs on Bornholm.]

C.S.D.I.C. (U.K.) S.R.G.G. 1118. [Recorded conversation of two German prisoners of war held in the United Kingdom. AFHRA A5415 frames 284–285]

M 159—General der Panzertruppen Von THOMA (GOC German AFRIKORPS) Captd MIDDLE EAST 4 Nov 42

CS/981 Generalleutnant KITTEL (Comd. METZ and Comd. 462 Volksgren. Div.) Captd METZ 22 Nov 44

Information received: 10 Jan 1945

TRANSLATION

KITTEL: (Re atom bomb). It's a perfectly horrible thing.

THOMA: A technical man has written about it, saying the problem has been completely solved theoretically, but that the process can't be controlled(?).

KITTEL: That's the question. At the passing-out parade of an officer's course the FÜHRER—I sent for one of the officers personally, for they were the ones who were at METZ—

THOMA: He's lying. There's absolutely no such thing as the atom business.

KITTEL: Unfortunately there is.

THOMA: Then he would have used it long ago.

KITTEL: No; he isn't using it, because the others have promised to retaliate with chemical warfare. [...]

THOMA: But there's no such thing as an atom bomb.

KITTEL: The experiments with it are carried out on BORNHOLM; the island has been evacuated and no-one may enter or leave the place.

THOMA: What do they do there?

KITTEL: They carry out their experiments there. Apparently they've got another trump card up their sleeve.

[Heinrich Kittel was a very high-ranking general in the German army and thus a valuable source of information, including some information on the German nuclear program. He was captured by Allied forces after being wounded at Metz, France, on 22 November 1944, so all of his knowledge about German activities was very up-to-date as of this recorded conversation. In contrast, General Wilhelm von Thoma had been captured in 1942 while fighting in North Africa, so he had no firsthand knowledge of subsequent developments (and was skeptical of secondhand reports).

Kittel's comments suggest that he was aware of one or more successful atomic bomb tests prior to his capture. The atomic bomb seemed to be much more than an abstract concept to him. For example, he said that:

- It was "a perfectly horrible thing."
- It "unfortunately" existed.
- The decision had already been made not to use it (implying it was available to use) due to Allied threats of retaliation by dropping mustard agent on German cities (see Section A.4.2).

If Kittel associated the atomic bomb most closely with Bornholm and seemed to believe that the bomb had been tested, that suggests that the test(s) occurred either on Bornholm or somewhere near Bornholm along the Baltic coast. That would be highly consistent with other information in Sections D.10–D.11.

Germany built a number of high-tech facilities on Bornholm, yet the local Danish resistance (and modern Danish museum curators) never figured out what exactly the Germans were doing. That indicates that German forces kept local Danish residents well away from the facilities, or else they would have seen and reported just what the Germans were doing there. Any high-ranking German military officer or official who visited would tour the German facilities and see little or nothing of the local residents, so as far as they were concerned, Bornholm was "evacuated"—not the whole island, just the relevant parts. Even today, the large majority of the Bornholm population lives in the town of Rønne on the west side of the island, and the rest is very sparsely populated. (Occupying Soviet forces removed all of the German equipment and documentation from Bornholm at the end of the war, perpetuating the mystery.)]

TRANSLATION

KITTEL: (Re atom bomb). It's a perfectly horrible thing.

THOMA : A technical man has written about it, saying the problem has been completely solved theoretically, but that the process can't be controlled(?).

KITTEL: That's the question. At the passing-out parade of an officer's course the FÜHRER - I sent for one of the officers personally, for they were the ones who were at METZ -

THOMA : He's lying. There's absolutely no such thing as the atom business.

KITTEL: Unfortunately there is.

THOMA : Then he would have used it long ago.

KITTEL: No; he isn't using it, because the others have promised to retaliate with chemical warfare.

THOMA : The others are far ahead in that respect.

KITTEL: To drop 'Lost' simultaneously over whole areas from 5000 aircraft or spray it from wave after wave of aircraft - the others can do that, but unfortunately we can't. Even in 1940 the English - I once had to carry out a practice gas attack for DOLLMANN, it had to be sprayed from aircraft and so on, areas had to be shut off by it, all quite up-to-date; and in order to be able to make it a completely up-to-date practice I was given the captured English instructions on the use of gas in attack; from them it appeared that they can drop a chemical similar to 'Lost' from a height of 8000 m.

THOMA: But there's no such thing as an atom bomb.

KITTEL: The experiments with it are carried out on BORNHOLM; the island has been evacuated and no-one may enter or leave the place.

THOMA : What do they do there?

KITTEL: They carry out their experiments there. Apparently they've got another trump card up their sleeve.

GERMAN TEXT

KITTEL: (Re 'atom bomb'): Das ist eine ganz scheussliche Sache.

THOMA : Da hat hier ein technischer Mann darüber geschrieben, es wäre theoretisch vollkommen gelöst, aber nicht zu bändigen(?).

KITTEL: Das ist ja die Frage. Der FÜHRER hat also bei der Entlassung eines Offiziersjahrgangs - ich habe mir eigens einen Offizier kommen lassen und zwar waren das die, die in METZ waren -

THOMA : Er lügt ja. Eine Atomgeschichte gibt es ja überhaupt garnicht.

KITTEL: Leider gibt's sie.

THOMA : Dann hätte er es schon längst gebraucht.

KITTEL: Nein, er bringt es deswegen nicht, weil ihm die anderen dafür den Gaskrieg versprochen haben.

THOMA : Da sind die anderen weit über.

KITTEL: Wenn man Lost aus 5000 Flugzeugen gleichzeitig in Flächen wirft oder hintereinander in Wellen abregnet - das können die anderen, wir können es leider nicht. Schon im Jahre '40 haben die Engländer - ich habe mal für den DOLLMANN eine Gasübung machen müssen, mit Flugzeug abregnen lassen und so Sachen, Ziehen von Sperriegeln, ganz modern, da kriegte ich, um eine ganz moderne Übungsanlage machen zu können, die erbeuteten englischen Vorschriften über Verwendung von Gas im Angriff, daraus ging hervor, dass sie aus 8000 m einen Lost-ähnlichen Kampfstoff abschmeissen können.

THOMA : Eine Atomgeschichte gibt es garnicht.

KITTEL: Diese Versuche sind auf BORNHOLM, die Insel ist geräumt worden, da darf niemand 'raus und 'rein.

THOMA : Was machen die dort?

KITTEL: Die machen da ihre Versuche. Sie haben offenbar noch irgendeinen Schlager.

Horace K. Calvert to R. V. Jones. 13 March 1945. [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL]

A report dated 27 February 1945 reflecting a conversation between Generalleutnant Kittel and General Eberbach (both German P.W.'s) has been received. The following dialogue is reported:

> KITTEL: I only wish that the Poles, with whom we shall have to co-operate economically afterwards in any case, will be reasonable, but they won't be reasonable, they don't know how to be. EAST PRUSSIA will become a new ALSACE-LORRAINE. Our children will again meet their death over that stupid question, even though the people are promising now to eradicate all wars. By that time new means will have been found; if aircraft are forbidden they'll discover other things.
>
> EBERBACH: The splitting up of the atom, or something like that.
>
> KITTEL: That already exists; that will come very soon; that will smash everything up.

You will recall that Kittel has made numerous references to German atom-splitting activity in the past and apparently is possessed of some information on the subject.

We understand that action on our request for permission to interrogate Kittel directly has been withheld. It is suggested that, in view of recurrence of discussion of this subject by Kittel, another attempt be made to arrange for direct interrogation.

The fact that Kittel's mind so frequently concerns itself with this subject, his knowledge of facts which we have corroborated from independent sources and the opportunities available to him for obtaining knowledge of such activity which might reasonably be expected to attach to one of his position all strongly persuade the belief that if properly approached he would be an extremely valuable source of information.

[Did Heinrich Kittel ever provide details of what he knew about the German nuclear program to Allied interrogators, friends or family in Germany, a diary or memoirs, etc.? Can any relevant records be found?

Note that Horace Calvert emphasized Kittel's "knowledge of facts which we have corroborated from independent sources and the opportunities available to him for obtaining knowledge of such [nuclear] activity." Calvert was a very highly placed Allied official investigating German nuclear work, and as of mid-March 1945, he seemed convinced that there was a serious German nuclear weapons program and that Kittel had accurate information about it.]

Dear Jones:

A report dated 27 February 1945 reflecting a conversation between Generalleutnant Kittel and General Eberbach (both German P.W.'s) has been received. The following dialogue is reported:

KITTEL : I only wish that the Poles, with whom we shall have to co-operate economically afterwards in any case, will be reasonable, but they won't be reasonable, they don't know how to be. EAST PRUSSIA will become a new ALSACE-LORRAINE. Our children will again meet their death over that stupid question, even though the people are promising now to eradicate all wars. By that time new means will have been found; if aircraft are forbidden they'll discover other things.

EBERBACH: The splitting up of the atom, or something nice like that.

KITTEL : That already exists; that will come very soon; that will smash everything up.

You will recall that Kittel has made numerous references to German atom-splitting activity in the past and apparently is possessed of some information on the subject.

We understand that action on our request for permission to interrogate Kittel directly has been withheld. It is suggested that, in view of recurrence of discussion of this subject by Kittel, another attempt be made to arrange for direct interrogation.

The fact that Kittel's mind so frequently concerns itself with this subject, his knowledge of facts which we have corroborated from independent sources and the opportunities available to him for obtaining knowledge of such activity which might reasonably be expected to attach to one of his position all strongly persuade the belief that if properly approached he would be an extremely valuable source of information.

Confirmation of Possibility of Uranium Deposits on Bornholm Island.

Uranium has been discovered on Danish owned island evacuated by the Russians two years ago. The deposit is said to be huge, with estimates running up to 500,000 tons. A Copenhagen dispatch to Svenska Dagbladet of Stockholm reports that the ore is contained in a granite outcropping running about 60 miles into the earth; the exploitable upper part alone, however, should yield 5,000 tons of uranium.

SOURCE: New York, 13 March 1948, NANA. Evaluation: B-2. CLASSIFICATION: (SECRET)

Strategic Vulnerability Branch Comment: The Strategic Vulnerability Branch has been able to uncover evidence* supporting the existence of radioactivity on the Danish island of Bornholm. The island is completely radioactive. Not only the land mass, but the surrounding sea water, atmosphere and local flora and fauna show radioactivity. The local inhabitants are large in stature, healthy and robust. Their virility extends over a period much longer than normal. There have been many cases of men 80 to 90 years old retaining their vigor.

This extraordinary radioactivity makes it highly probable that uranium exists on the island, possibly in large quantities. It has been reported that the island is rich in radium and thorium. This would indicate that a uranium deposit of 5,000 tons may actually exist on the island. Bornholm was evacuated by the Russians in 1946. It is situated within an area of Soviet pressure.

Reference: Item of Interest of 16 March 1948. *Source: Biology of Radium and Uranium published by Czech Radiological Institute, Prague 1932. (Mr. Rosenzweig, Ext. 71911).

[Just exactly what nuclear work was conducted on Bornholm by the Germans during the war, and what was removed by the Russians after the war?

Although the idea (apparently from the 1932 source) that natural radioactivity can promote health is now laughably outdated, the above document confirms that scientists knew there was significant radioactivity on Bornholm both before and after World War II. If Bornholm's radioactivity was known by scientists in Prague in 1932, that information might be one factor that attracted German interest in the island during the war. If there were uranium or thorium deposits, Germany may have mined them during the war.

If Bornholm was known to have elevated levels of radioactivity after the war, were those due to the mining of natural deposits, wartime work on enriching uranium or breeding plutonium on the island, or wartime tests of nuclear explosives on or near the island?]

D.5 Fission Reactors for Breeding Pu-239 and/or U-233

[Ludwig Bewilogua (German, 1906–1983), Kurt Diebner, Paul Harteck, Otto Haxel (German, 1909–1998), and many others worked in teams trying to develop fission reactors suitable for breeding plutonium-239 from natural uranium-238 or uranium-233 from natural thorium-232. Two reactors were on the brink of criticality by the end of the war, and there is some evidence that other reactors may have actually become operational during the war. This section covers:

D.5.1. Scientific knowledge about breeding Pu-239 and U-233.

D.5.2. Known and suspected fission reactors.

For breeding using particle accelerators (electronuclear breeding), see Section D.6.]

D.5.1 Scientific Knowledge About Breeding Pu-239 and U-233

[The following documents demonstrate the knowledge of scientists in Germany:

- By 1934, scientists knew that element 94, or plutonium-239, could be produced and purified (pp. 3794–3795).
- No later than 1940, scientists understood that plutonium-239 could be used to create a bomb (pp. 3800–3826).
- During the war, scientists also understood that uranium-233 could be produced and used to create a bomb (pp. 3832–3836).]

Ida Tacke Noddack. 1934. Über das Element 93. *Angewandte Chemie.* 47:37:653–655.

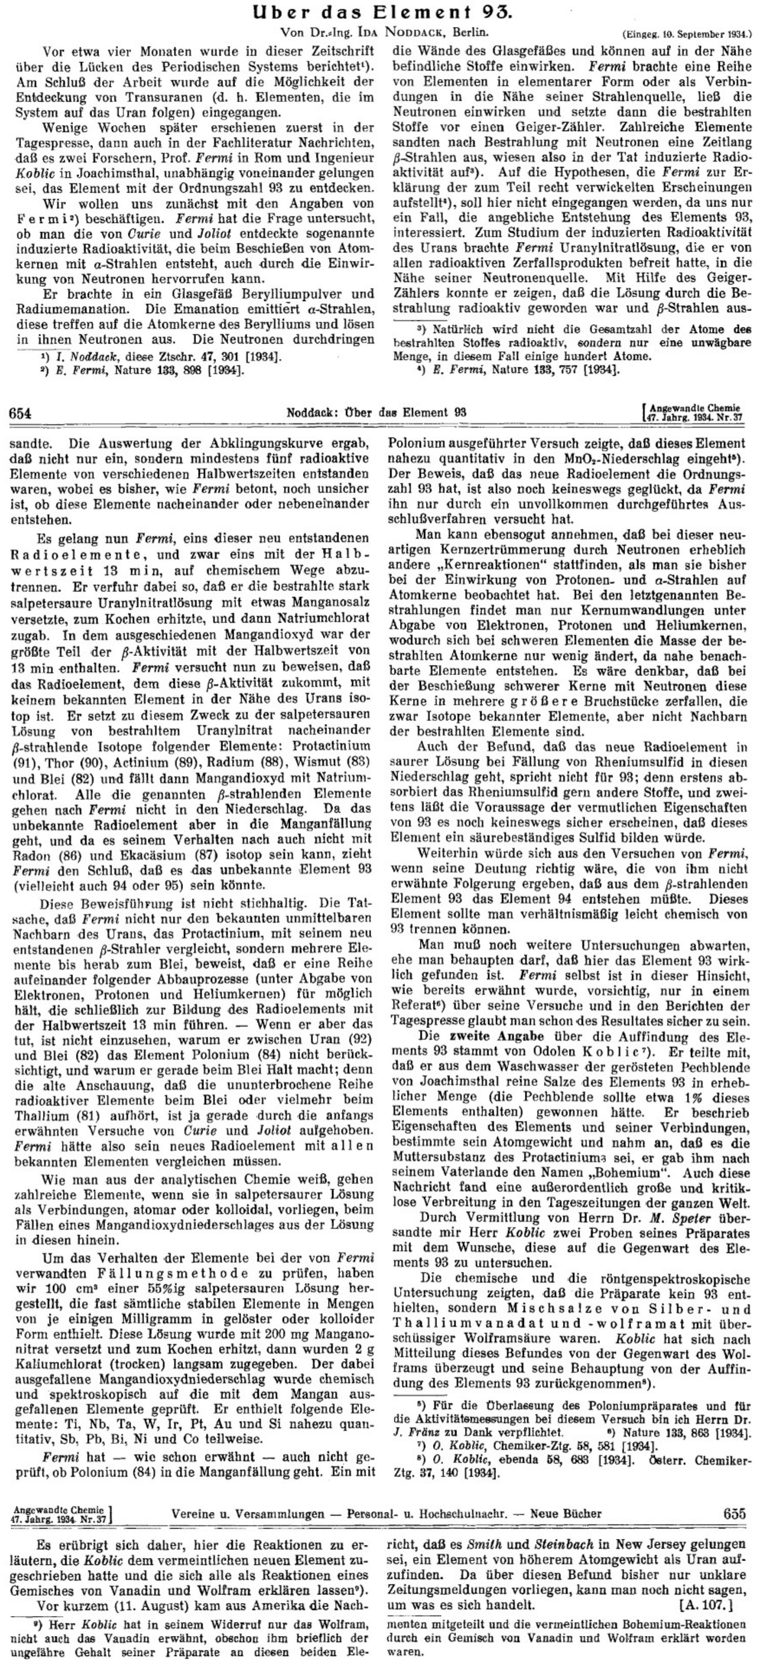
Man kann ebensogut annehmen, daß bei dieser neuartigen Kernzertrümmerung durch Neutronen erheblich andere “Kernreaktionen” stattfinden, als man sie bisher bei der Einwirkung von Protonen- und α-Strahlen auf Atomkerne beobachtet hat. Bei den letztgenannten Bestrahlungen findet man nur Kernumwandlungen unter Abgabe von Elektronen, Protonen und Heliumkernen, wodurch sich bei schweren Elementen die Masse der bestrahlten Atomkerne nur wenig ändert, da nahe benachbarte Elemente entstehen. Es wäre denkbar, daß bei der Beschießung schwerer Kerne mit Neutronen diese Kerne in mehrere größere Bruchstücke zerfallen, die zwar Isotope bekannter Elemente, aber nicht Nachbarn der bestrahlten Elemente sind.

[...*A*]us dem β-strahlenden Element 93 das Element 94 entstehen müßte. Dieses Element sollte man verhältnismäßig leicht chemisch von 93 trennen können.

One could assume equally well that when neutrons are used to produce nuclear disintegrations, some distinctly new nuclear reactions take place which have not been observed previously with proton or alpha-particle bombardment of atomic nuclei. In the past one has found that transmutations of nuclei only take place with the emission of electrons, protons, or helium nuclei, so that the heavy elements change their mass only a small amount to produce near neighboring elements. When heavy nuclei are bombarded by neutrons, it is conceivable that the nucleus breaks up into several large fragments, which would of course be isotopes of known elements but would not be neighbors of the irradiated element.

[...B]eta decay of element 93 would produce element 94. It should be relatively easy to separate this chemically from element 93.

***Angewandte Chemie* 47:37:653-655 (1934)**



Uber das Element 93.

Von Dr.-Ing. IDA NODDACK, Berlin.

(Eingeg. 10. September 1934.)

Vor etwa vier Monaten wurde in dieser Zeitschrift über die Lücken des Periodischen Systems berichtet1). Am Schluß der Arbeit wurde auf die Möglichkeit der Entdeckung von Transuranen (d. h. Elementen, die im System auf das Uran folgen) eingegangen.

Wenige Wochen später erschienen zuerst in der Tagespresse, dann auch in der Fachliteratur Nachrichten, daß es zwei Forschern, Prof. *Fermi* in Rom und Ingenieur *Koblic* in Joachimsthal, unabhängig voneinander gelungen sei, das Element mit der Ordnungszahl 93 zu entdecken.

Wir wollen uns zunächst mit den Angaben von Fermi2) beschäftigen. *Fermi* hat die Frage untersucht, ob man die von *Curie* und *Joliot* entdeckte sogenannte induzierte Radioaktivität, die beim Beschießen von Atomkernen mit α-Strahlen entsteht, auch durch die Einwirkung von Neutronen hervorrufen kann.

Er brachte in ein Glasgefäß Berylliumpulver und Radiumemanation. Die Emanation emittiert α-Strahlen, diese treffen auf die Atomkerne des Berylliums und lösen in ihnen Neutronen aus. Die Neutronen durchdringen die Wände des Glasgefäßes und können auf in der Nähe befindliche Stoffe einwirken. *Fermi* brachte eine Reihe von Elementen in elementarer Form oder als Verbindungen in die Nähe seiner Strahlenquelle, ließ die Neutronen einwirken und setzte dann die bestrahlten Stoffe vor einen Geiger-Zähler. Zahlreiche Elemente sandten nach Bestrahlung mit Neutronen eine Zeitlang β-Strahlen aus, wiesen also in der Tat induzierte Radioaktivität auf3). Auf die Hypothesen, die *Fermi* zur Erklärung der zum Teil recht verwickelten Erscheinungen aufstellt4), soll hier nicht eingegangen werden, da uns nur ein Fall, die angebliche Entstehung des Elements 93, interessiert. Zum Studium der induzierten Radioaktivität des Urans brachte *Fermi* Uranylnitratlösung, die er von allen radioaktiven Zerfallsprodukten befreit hatte, in die Nähe seiner Neutronenquelle. Mit Hilfe des Geiger-Zählers konnte er zeigen, daß die Lösung durch die Bestrahlung radioaktiv geworden war und β-Strahlen aussandte. Die Auswertung der Abklingungskurve ergab, daß nicht nur ein, sondern mindestens fünf radioaktive Elemente von verschiedenen Halbwertszeiten entstanden waren, wobei es bisher, wie *Fermi* betont, noch unsicher ist, ob diese Elemente nacheinander oder nebeneinander entstehen.

---

1) *I. Noddack*, diese Ztschr. **47**, 301 [1934].

2) *E. Fermi*, Nature **133**, 898 [1934].

3) Natürlich wird nicht die Gesamtzahl der Atome des bestrahlten Stoffes radioaktiv, *sondern* nur eine unwägbare Menge, in diesem Fall einige hundert Atome.

4) *E. Fermi*, Nature **133**, 757 [1934].

Es gelang nun *Fermi*, eins dieser neu entstandenen Radioelemente, und zwar eins mit der Halbwertszeit 13 min, auf chemischem Wege abzutrennen. Er verfuhr dabei so, daß er die bestrahlte stark salpetersaure Uranylnitratlösung mit etwas Manganosalz versetzte, zum Kochen erhitzte, und dann Natriumchlorat zugab. In dem ausgeschiedenen Mangandioxyd war der größte Teil der β-Aktivität mit der Halbwertszeit von 13 min enthalten. *Fermi* versucht nun zu beweisen, daß das Radioelement, dem diese β-Aktivität zukommt, mit keinem bekannten Element in der Nähe des Urans isotop ist. Er setzt zu diesem Zweck zu der salpetersauren Lösung von bestrahltem Uranylnitrat nacheinander β-strahlende Isotope folgender Elemente: Protactinium (91), Thor (90), Actinium (89), Radium (88), Wismut (83) und Blei (82) und fällt dann Mangandioxyd mit Natriumchlorat. Alle die genannten β-strahlenden Elemente gehen nach *Fermi* nicht in den Niederschlag. Da das unbekannte Radioelement aber in die Manganfällung geht, und da es seinem Verhalten nach auch nicht mit Radon (86) und Ekacäsium (87) isotop sein kann, zieht *Fermi* den Schluß, daß es das unbekannte Element 93 (vielleicht auch 94 oder 95) sein könnte.

Diese Beweisführung ist nicht stichhaltig. Die Tatsache, daß *Fermi* nicht nur den bekannten unmittelbaren Nachbarn des Urans, das Protactinium, mit seinem neu entstandenen β-Strahler vergleicht, sondern mehrere Elemente bis herab zum Blei, beweist, daß er eine Reihe aufeinander folgender Abbauprozesse (unter Abgabe von Elektronen, Protonen und Heliumkernen) für möglich hält, die schließlich zur Bildung des Radioelements mit der Halbwertszeit 13 min führen. — Wenn er aber das tut, ist nicht einzusehen, warum er zwischen Uran (92) und Blei (82) das Element Polonium (84) nicht berücksichtigt, und warum er gerade beim Blei Halt macht; denn die alte Anschauung, daß die ununterbrochene Reihe radioaktiver Elemente beim Blei oder vielmehr beim Thallium (81) aufhört, ist ja gerade durch die anfangs erwähnten Versuche von *Curie* und *Joliot* aufgehoben. *Fermi* hätte also sein neues Radioelement mit allen bekannten Elementen vergleichen müssen.

Wie man aus der analytischen Chemie weiß, gehen zahlreiche Elemente, wenn sie in salpetersaurer Lösung als Verbindungen, atomar oder kolloidal, vorliegen, beim Fällen eines Mangandioxydniederschlages aus der Lösung in diesen hinein.

Um das Verhalten der Elemente bei der von *Fermi* verwandten Fällungsmethode zu prüfen, haben wir 100 cm^3 einer 55%ig salpetersauren Lösung hergestellt, die fast sämtliche stabilen Elemente in Mengen von je einigen Milligramm in gelöster oder kolloider Form enthielt. Diese Lösung wurde mit 200 mg Manganonitrat versetzt und zum Kochen erhitzt, dann wurden 2 g Kaliumchlorat (trocken) langsam zugegeben. Der dabei ausgefallene Mangandioxydniederschlag wurde chemisch und spektroskopisch auf die mit dem Mangan ausgefallenen Elemente geprüft. Er enthielt folgende Elemente: Ti, Nb, Ta, W, Ir, Pt, Au und Si nahezu quantitativ, Sb, Pb, Bi, Ni und Co teilweise.

Fermi hat — wie schon erwähnt — auch nicht geprüft, ob Polonium (84) in die Manganfällung geht. Ein mit Polonium ausgeführter Versuch zeigte, daß dieses Element nahezu quantitativ in den MnO_2-Niederschlag eingeht5). Der Beweis, daß das neue Radioelement die Ordnungszahl 93 hat, ist also noch keineswegs geglückt, da *Fermi* ihn nur durch ein unvollkommen durchgeführtes Ausschlußverfahren versucht hat.

Man kann ebensogut annehmen, daß bei dieser neuartigen Kernzertrümmerung durch Neutronen erheblich andere „Kernreaktionen" stattfinden, als man sie bisher bei der Einwirkung von Protonen- und α-Strahlen auf Atomkerne beobachtet hat. Bei den letztgenannten Bestrahlungen findet man nur Kernumwandlungen unter Abgabe von Elektronen, Protonen und Heliumkernen, wodurch sich bei schweren Elementen die Masse der bestrahlten Atomkerne nur wenig ändert, da nahe benachbarte Elemente entstehen. Es wäre denkbar, daß bei der Beschießung schwerer Kerne mit Neutronen diese Kerne in mehrere größere Bruchstücke zerfallen, die zwar Isotope bekannter Elemente, aber nicht Nachbarn der bestrahlten Elemente sind.

Auch der Befund, daß das neue Radioelement in saurer Lösung bei Fällung von Rheniumsulfid in diesen Niederschlag geht, spricht nicht für 93; denn erstens absorbiert das Rheniumsulfid gern andere Stoffe, und zweitens läßt die Voraussage der vermutlichen Eigenschaften von 93 es noch keineswegs sicher erscheinen, daß dieses Element ein säurebeständiges Sulfid bilden würde.

Weiterhin würde sich aus den Versuchen von *Fermi*, wenn seine Deutung richtig wäre, die von ihm nicht erwähnte Folgerung ergeben, daß aus dem β-strahlenden Element 93 das Element 94 entstehen müßte. Dieses Element sollte man verhältnismäßig leicht chemisch von 93 trennen können.

Man muß noch weitere Untersuchungen abwarten, ehe man behaupten darf, daß hier das Element 93 wirklich gefunden ist. *Fermi* selbst ist in dieser Hinsicht, wie bereits erwähnt wurde, vorsichtig, nur in einem Referat6) über seine Versuche und in den Berichten der Tagespresse glaubt man schon des Resultates sicher zu sein.

Die **zweite Angabe** über die Auffindung des Elements 93 stammt von Odolen Koblic7). Er teilte mit, daß er aus dem Waschwasser der gerösteten Pechblende von Joachimsthal reine Salze des Elements 93 in erheblicher Menge (die Pechblende sollte etwa 1% dieses Elements enthalten) gewonnen hätte. Er beschrieb Eigenschaften des Elements und seiner Verbindungen, bestimmte sein Atomgewicht und nahm an, daß es die Muttersubstanz des Protactiniums sei, er gab ihm nach seinem Vaterlande den Namen „Bohemium". Auch diese Nachricht fand eine außerordentlich große und kritiklose Verbreitung in den Tageszeitungen der ganzen Welt.

Durch Vermittlung von Herrn Dr. *M. Speter* übersandte mir Herr *Koblic* zwei Proben seines Präparates mit dem Wunsche, diese auf die Gegenwart des Elements 93 zu untersuchen.

Die chemische und die röntgenspektroskopische Untersuchung zeigten, daß die Präparate kein 93 enthielten, sondern Mischsalze von Silber- und Thalliumvanadat und -wolframat mit überschüssiger Wolframsäure waren. *Koblic* hat sich nach Mitteilung dieses Befundes von der Gegenwart des Wolframs überzeugt und seine Behauptung von der Auffindung des Elements 93 zurückgenommen8).

---

5) Für die Überlassung des Poloniumpräparates und für die Aktivitätsmessungen bei diesem Versuch bin ich Herrn Dr. *J. Fränz* zu Dank verpflichtet.

6) Nature **133**, 863 [1934].

7) *O. Koblic*, Chemiker-Ztg. **58**, 581 [1934].

8) *O. Koblic*, ebenda **58**, 683 [1934]. Österr. Chemiker-Ztg. **37**, 140 [1934].

Es erübrigt sich daher, hier die Reaktionen zu erläutern, die *Koblic* dem vermeintlichen neuen Element zugeschrieben hatte und die sich alle als Reaktionen eines Gemisches von Vanadin und Wolfram erklären lassen9).

Vor kurzem (11. August) kam aus Amerika die Nachricht, daß es *Smith* und *Steinbach* in New Jersey gelungen sei, ein Element von höherem Atomgewicht als Uran aufzufinden. Da über diesen Befund bisher nur unklare Zeitungsmeldungen vorliegen, kann man noch nicht sagen, um was es sich handelt. [A. 107.]

---

9) Herr *Koblic* hat in seinem Widerruf nur das Wolfram, nicht auch das Vanadin erwähnt, obschon ihm brieflich der ungefähre Gehalt seiner Präparate an diesen beiden Elementen mitgeteilt und die vermeintlichen Bohemium-Reaktionen durch ein Gemisch von Vanadin und Wolfram erklärt worden waren.

An den Führer und Reichskanzler Herrn Adolf Hitler
Berlin. 169

Betrifft: Transuran Radium A bis C.

Mein Chemiker A.Blau in Bad Godesberg hatte während seinem Studium auf der Technichen Hochschule in Hannover im Jahre 1903 an den Versuchen mit Radium teilgenommen, welches das Ehepaar Curie in Frankreich im Jahre 1898 durch Zufall entdeckt hatte. Der hohe Wert von Radium für die Jndustrie und bei der Krebsbehandlung usw. ist schon lange von prominenten Vertretern der Wissenschaft aller Länder anerkannt. Leider gibt es von diesem kostbaren Element auf der ganzen Welt nur etwa 500 Gramm, und 1Gramm kostet heute noch 240 000 Mark. Da die ganze Welt Radium braucht, sind eifrige Forscher der ganzen Welt bemüht, dem Mangel an Radium durch die Erfindung von Künstlichem Radium zu begegnen, was bis zur Stunde noch keinem gelungen ist.

Unter den Männern, die sich um die Herstellung von künstlichem Radium bemühten, befand sich auch der oben erwähnte Chemiker A.Blau. Nach zehnjährigen und überaus schwierigen Versuchen gelang es ihm als einzigster Forscher künstliches Radium in jeder gewünschten Menge und Stärke herzustellen. Seine Erfindung erläuterte Blau in einem Schreiben an den ehemaligen deutschen Kronprinzen Wilhelm, der ihn mit einem Empfehlungsschreiben an Herrn Adolf Hitler verwies.

Am 7.12.31. ging ein entsprechendes Schreiben an Herrn Adolf Hitler, Braunes Haus in München, welches die Nr.B.J.1/203 a trug, dem eine Beschreibung der Erfindung beigegeben war. Da keine Antwort erfolgte, benutzte der Chemiker A.Blau den Besuch des Herrn Adolf Hitler am 27.1.32. im Hotel Dreesen zu Bad Godesberg zu einer Unterredung, die ihm auch gewährt wurde. Bei der Aussprache, an der sich auch Herr Oberleutnant Brückner beteiligte, überreichte Blau das kronprinzliche Empfehlungsschreiben, und Herr Adolf Hitler und Herr Oberleutnant Brückner versprachen dem Erfinder auf die Sache zurückzukommen. Bei einer Flasche Rheinwein machte der Erfinder eingehende Ausführungen über sein künstliches Radium, und Herr Oberleutnant Brückner nahm das kronprinzliche Empfehlungsschreiben sowie die schriftliche Begründung der Erfindung an sich. Der Erfinder schrieb am 4.2.32. unter Nr.B.J.1/203 a nachstehenden Brief:

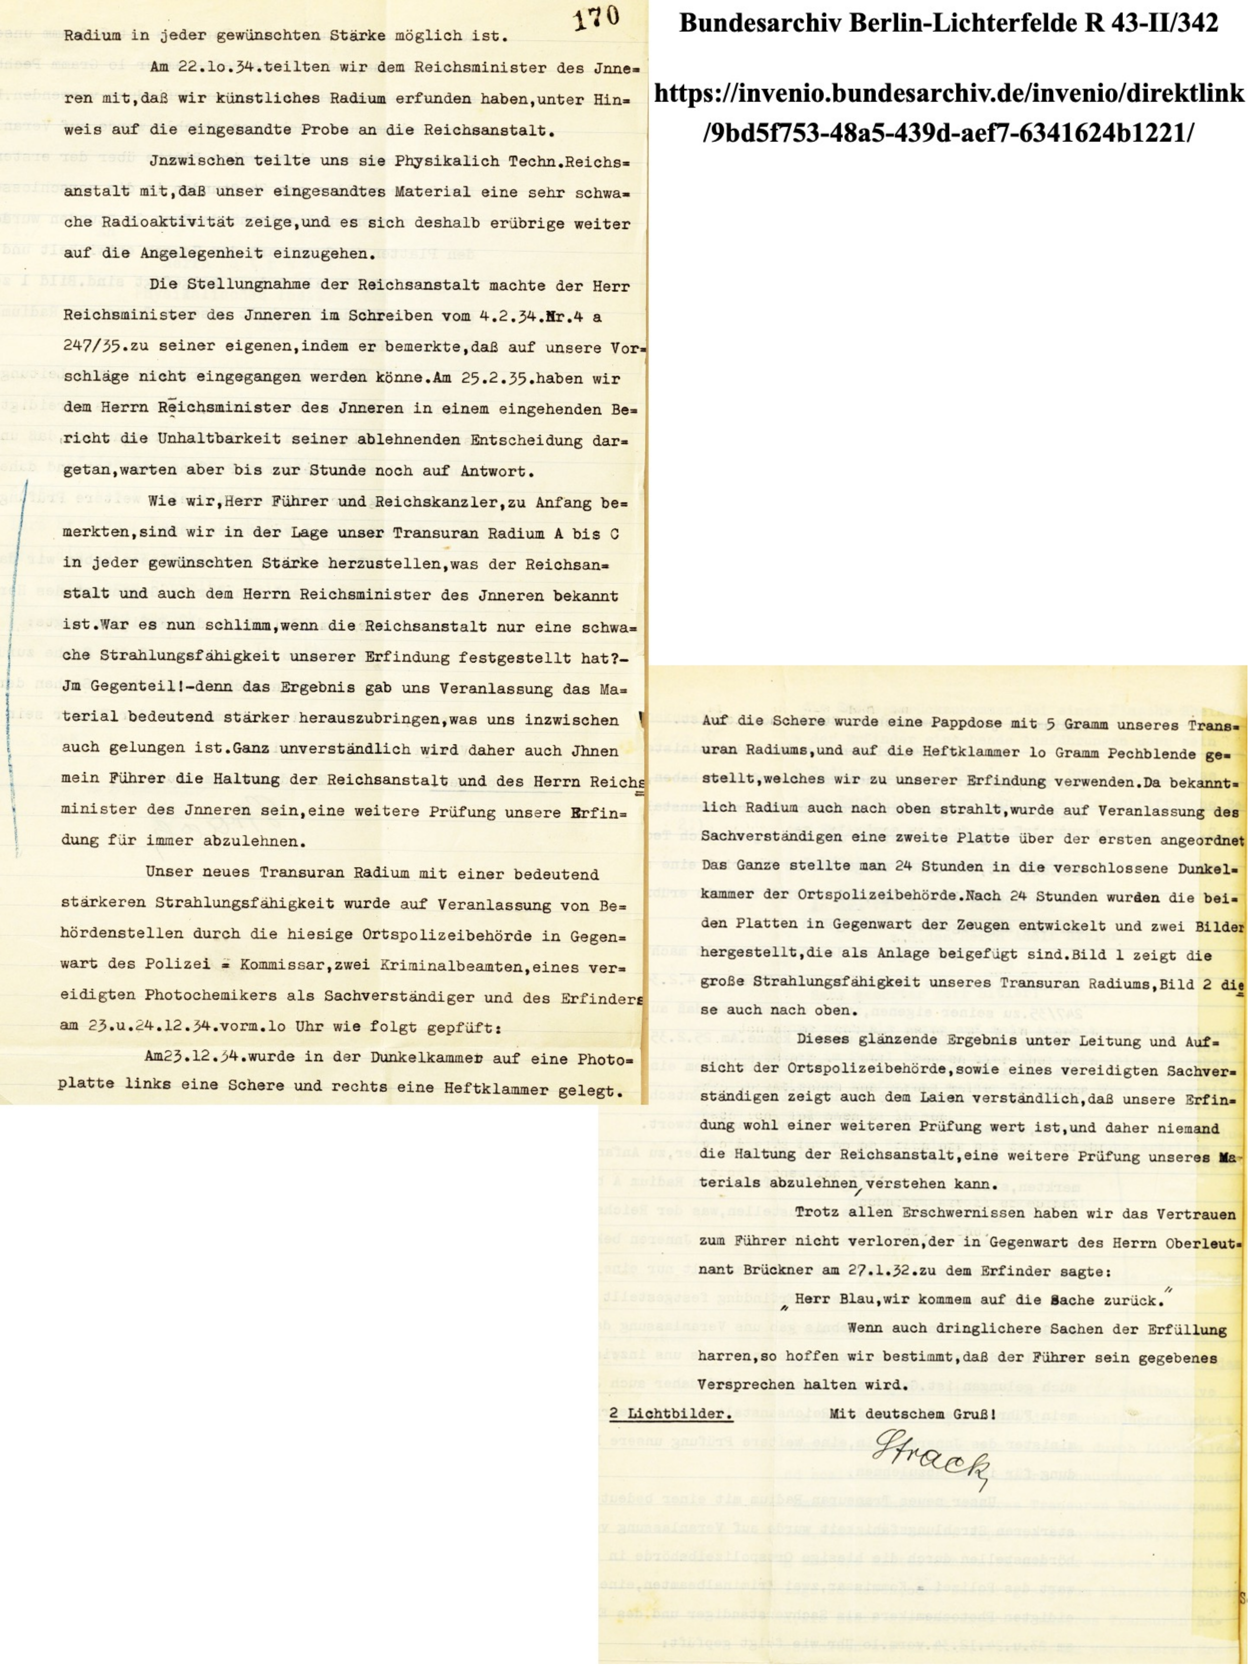
> An den Völkischen Beobachter
> z.H. des Herrn Adolf Hitler
> München.
>
> Sehr geehrter Herr Hitler!
>
> Jch nehme nochmals Bezug auf mein Angebot vom 7.12.31. und meiner persönlichen Rücksprache mit Jhnen und Herrn Oberleutnant Brückner im Hotel Dreesen hier über mein obiges Angebot laut Prospekt und frage höflichst an, wann ich zur Vorführung resp. praktischen Ausführung meiner Erfindung über radioaktive Elektrolyse pp. nach dort kommen soll, und bitte mir umgehend Nachricht zukommen zu lassen.
>
> Jch bemerke noch kurz, daß ich Jhnen den absoluten Beweis für meine Erfindung bei der Vorführung erbringe, was für Sie und Jhrer parteipolitischen Richtung von weittragender Bedeutung ist.
>
> 1. Anlage!
>
> Hochachtungsvoll ergebenst!
>
> gez. A.Blau.

Leider ist auf das alles bis zur Stunde noch nichts geschehen.

Jnzwischen hat der Chemiker A.Blau trotz dieser Enttäuschung an seiner Erfindung weiter gearbeitet, und mit dem Unterzeichneten ein Physikalisches Jnstitut für radioaktive Substanzen in Bad Godesberg gegründet. die Strahlungsfähigkeit unseres Transuran Radiums haben wir mehrmals durch Lichtbilder bewiesen, und somit den Beweis für unsere Behauptungen erbracht

Umden Radiumgehalt unseres Transuran Radiums genau festzustellen, sind sehr teuere Apparate erforderlich, zu deren Anschaffung uns die Mittel fehlen. UM nun für weitere Arbeiten eine Grundlage zu haben, oder besser gesagt, um Klarheit darüber zu bekommen, wie stark der Radiumgehalt unseres Transuran Radiums ist, schickten wir am 6.10.34. ein Gramm von unserer Erfindung an die Physikalich Technische Reichsanstalt Berlin - Charlottenburg und baten um Prüfung nach seinem Radiumgehalt, wobei wir bemerkten, das uns die Herstellung von künstlichem

Figure D.334: 20 May 1935 proposal to Adolf Hitler to artificially create radioactive elements beyond uranium for applications of national importance [Bundesarchive Berlin-Lichterfelde R 43-II/342 https://invenio.bundesarchiv.de/invenio/direktlink/9bd5f753-48a5-439d-aef7-6341624b1221/]. Although the scientific details and merits of this particular proposal are unclear, at the very least it demonstrates very early German interest in creating and harnessing transuranic elements.



170

Radium in jeder gewünschten Stärke möglich ist.

Am 22.10.34.teilten wir dem Reichsminister des Jnneren mit,daß wir künstliches Radium erfunden haben,unter Hinweis auf die eingesandte Probe an die Reichsanstalt.

Jnzwischen teilte uns sie Physikalich Techn.Reichsanstalt mit,daß unser eingesandtes Material eine sehr schwache Radioaktivität zeige,und es sich deshalb erübrige weiter auf die Angelegenheit einzugehen.

Die Stellungnahme der Reichsanstalt machte der Herr Reichsminister des Jnneren im Schreiben vom 4.2.34.Nr.4 a 247/35.zu seiner eigenen,indem er bemerkte,daß auf unsere Vorschläge nicht eingegangen werden könne.Am 25.2.35.haben wir dem Herrn Reichsminister des Jnneren in einem eingehenden Bericht die Unhaltbarkeit seiner ablehnenden Entscheidung dargetan,warten aber bis zur Stunde noch auf Antwort.

Wie wir,Herr Führer und Reichskanzler,zu Anfang bemerkten,sind wir in der Lage unser Transuran Radium A bis C in jeder gewünschten Stärke herzustellen,was der Reichsanstalt und auch dem Herrn Reichsminister des Jnneren bekannt ist.War es nun schlimm,wenn die Reichsanstalt nur eine schwache Strahlungsfähigkeit unserer Erfindung festgestellt hat?-Jm Gegenteil!-denn das Ergebnis gab uns Veranlassung das Material bedeutend stärker herauszubringen,was uns inzwischen auch gelungen ist.Ganz unverständlich wird daher auch Jhnen mein Führer die Haltung der Reichsanstalt und des Herrn Reichsminister des Jnneren sein,eine weitere Prüfung unsere Erfindung für immer abzulehnen.

Unser neues Transuran Radium mit einer bedeutend stärkeren Strahlungsfähigkeit wurde auf Veranlassung von Behördenstellen durch die hiesige Ortspolizeibehörde in Gegenwart des Polizei = Kommissar,zwei Kriminalbeamten,eines vereidigten Photochemikers als Sachverständiger und des Erfinders am 23.u.24.12.34.vorm.10 Uhr wie folgt gepfüft:

Am23.12.34.wurde in der Dunkelkammer auf eine Photoplatte links eine Schere und rechts eine Heftklammer gelegt. Auf die Schere wurde eine Pappdose mit 5 Gramm unseres Transuran Radiums,und auf die Heftklammer 10 Gramm Pechblende gestellt,welches wir zu unserer Erfindung verwenden.Da bekanntlich Radium auch nach oben strahlt,wurde auf Veranlassung des Sachverständigen eine zweite Platte über der ersten angeordnet Das Ganze stellte man 24 Stunden in die verschlossene Dunkelkammer der Ortspolizeibehörde.Nach 24 Stunden wurden die beiden Platten in Gegenwart der Zeugen entwickelt und zwei Bilder hergestellt,die als Anlage beigefügt sind.Bild 1 zeigt die große Strahlungsfähigkeit unseres Transuran Radiums,Bild 2 die se auch nach oben.

Dieses glänzende Ergebnis unter Leitung und Aufsicht der Ortspolizeibehörde,sowie eines vereidigten Sachverständigen zeigt auch dem Laien verständlich,daß unsere Erfindung wohl einer weiteren Prüfung wert ist,und daher niemand die Haltung der Reichsanstalt,eine weitere Prüfung unseres Materials abzulehnen, verstehen kann.

Trotz allen Erschwernissen haben wir das Vertrauen zum Führer nicht verloren,der in Gegenwart des Herrn Oberleutnant Brückner am 27.1.32.zu dem Erfinder sagte:

„Herr Blau,wir kommem auf die Sache zurück."

Wenn auch dringlichere Sachen der Erfüllung harren,so hoffen wir bestimmt,daß der Führer sein gegebenes Versprechen halten wird.

2 Lichtbilder. Mit deutschem Gruß!

Strack

Figure D.335: 20 May 1935 proposal to Adolf Hitler to artificially create radioactive elements beyond uranium for applications of national importance [Bundesarchive Berlin-Lichterfelde R 43-II/342 https://invenio.bundesarchiv.de/invenio/direktlink/9bd5f753-48a5-439d-aef7-6341624b1221/]. Although the scientific details and merits of this particular proposal are unclear, at the very least it demonstrates very early German interest in creating and harnessing transuranic elements.

G-55. Josef Schintlmeister and Friedrich Hernegger. Über ein bisher unbekanntes alphastrahlendes chemisches Element. June 1940.

Mit diesen Konzentraten wird gegenwärtig das chemische Verhalten des neuen Elementes weiter erforscht. Seine bisher festgestellten chemischen Eigenschaften ermöglichen übrigens bereits eine weitgehende Anreicherung, prinzipiell sogar schon die Reindarstellung. Sie können unserer Auffassung nach nur so gedeutet werden, dass ein Eka-Osmium (Ordnungszahl 94) oder allenfalls ein Eka-Rhenium (Ordnungszahl 93) vorliegt.

With these concentrates, the chemical behavior of the new element is currently being researched further. Incidentally, its chemical properties that have hitherto been determined already make it possible to enrich it extensively, and in principle, even to purify it. In our opinion, they can only be interpreted as having an eka-osmium (element 94) or at least an eka-rhenium (element 93) present.

Einleitung

Enthält ein Mineral winzige Einschlüsse radioaktiver Substanzen,so wird es durch die α-Strahlen verfärbt.Um die Einschlüsse bilden sich also Verfärbungshöfe aus.J.Joly fand nun im Jahre 1922 in Glimmer manchmal Höfe,deren Halbmesser auf eine Reichweite der erzeugenden α-Strahlen in Luft von etwa 1 cm und 2 cm schliessen lassen.α-Strahlen solcher Reichweite waren jedoch nicht bekannt.Die Strahlen dieser Reichweiten wurden späterhin von verschiedensten Forschern beobachtet.[1] Dabei wurden nicht blos aus Verfärbungshöfen in Glimmern,sondern zuerst von H. Ziegert 1928 auch durch Messung der von den einzelnen Strahlen erzeugten Ionisation die Reichweite bestimmt. Da diese verschiedenen Methoden dieselben Reichweiten ergaben,war damit zugleich bewiesen,dass α-Strahlen und nicht irgendwelche andere Strahlen vorliegen.Ziegert fand diese Strahlen in Zink wieder,konnte jedoch den Träger dieser Strahlung durch chemische Operationen von Zink abtrennen.Er schreibt am Schlusse

Patentansprüche.

1. Verfahren zur Energieerzeugung aus ^{238}U, dadurch gekennzeichnet, daß ^{238}U mit zwei thermischen Neutronen beschossen wird, wodurch zunächst über β-Zerfälle ein Element 94 der Masse 239 entsteht, das durch das zweite Neutron eine Kernspaltung erfährt, bei der sowohl eine ungeheure Energie abgegeben wird, als auch neue Neutronen und Kerne entstehen.

2. Verfahren zur Energiegewinnung aus ^{238}U nach Anspruch 1, dadurch gekennzeichnet, daß die zur Umwandlung größerer Mengen des ^{238}U in Element 94 notwendigen Neutronen in einer "Uranmaschine" erzeugt werden.

Patent claims.

1. Method for the production of energy from ^{238}U, characterized in that ^{238}U is bombarded with two thermal neutrons, whereby after beta decays forms an element 94 with mass 239, which by the second neutron experiences a nuclear fission, in which both a tremendous energy is released, as well as new neutrons and nuclei arise.

2. The method for generating energy from ^{238}U according to claim 1, characterized in that the neutrons necessary to convert large quantities of the ^{238}U into element 94 are generated in a "uranium machine."

3. Verfahren zur Energieerzeugung aus ^{238}U bzw. Element 94 nach Anspruch 1, dadurch gekennzeichnet, daß das durch Neutronenanlagerung erzeugte Element 94 durch bekannte chemische Verfahren von dem verbleibenden Uran abgetrennt wird und dann in reiner bzw. geeignet wählbarer Konzentration verwendbar vorliegt.

4. Verfahren zur Energieerzeugung und Neutronenproduktion aus schwer spaltbaren schweren Kernen (z.B. ^{238}U, Thorium, Blei, Bismut etc.), dadurch gekennzeichnet, daß das nach Anspruch 3 erhaltene Element 94 diesen Elementen in geeigneter Menge zugesetzt wird, so daß sie einen autokatalytischen Spaltprozess durch Neutronen durchmachen können, bei dem Energie erzeugt wird und neue Atomkerne entstehen.

5. Verfahren zur explosiven Erzeugung von Energie und Neutronen aus der Spaltung des Elements 94, dadurch gekennzeichnet, daß das nach Anspruch 3 hergestellte Element 94 in solcher Menge an einen Ort gebracht wird, z.B. in eine Bombe, daß die bei einer Spaltung entstehenden Neutronen in der überwiegenden Mehrzahl zur Anregung neuer Spaltungen verbraucht werden und nicht die Substanz verlassen.

6. Verfahren zur Erzeugung sehr kleiner handlicher Maschinen zur Gewinnung von Kernenergie und von Neutronen, z.T. nach Anspruch 3 and 4 und unter Zugrundelegung der Kenntnisse über eine "Uranmaschine", dadurch gekennzeichnet, daß man nur so viel Element 94 an einem Ort vereinigt, (u.U. nach Beimischung geeigneter, neutronenbremsender und/oder absorbierender Zusatzelemente) daß Explosionen vermieden werden, und die Energieabgabe kontinuierlich erfolgt.

3. The method for generating energy from the element U or element 94 according to claim 1, characterized in that the neutron-produced element 94 is separated from the remaining uranium by known chemical methods, and then is available in pure or suitably selected concentration.

4. Method for the production of energy and neutron production from heavy fissionable nuclei (for example, ^{238}U, thorium, lead, bismuth, etc.), characterized in that the element 94 obtained according to claim 3 is added to these elements in a suitable amount, so that they can undergo an autocatalytic fission process by neutrons, in which energy is generated and new atomic nuclei are formed.

5. Method for the explosive generation of energy and neutrons from the fission of the element 94, characterized in that the element 94 produced according to claim 3 is brought to a location in such an amount, e.g. in a bomb, that the vast majority of the neutrons produced during each fission event are used to produce new fission events and do not leave the substance.

6. Process for the production of very small, handy machines for obtaining nuclear energy and neutrons, in part according to claims 3 and 4, and on the basis of the knowledge of a "uranium machine," characterized in that one brings together only so much element 94 in one place (depending on the admixture of suitable, neutron-slowing and/or absorbing additional elements) that explosions are avoided and the energy is discharged continuously.

Eine Möglichkeit der Energiegewinnung aus ^{238}U.

v. C. F. v. Weizsäcker

1. Problemstellung. Es folgt aus der Theorie von Bohr und Wheeler und wurde unlängst durch Nier experimentell bestätigt, dass der Kern ^{238}U nicht durch ein thermisches Neutron gespalten werden kann. Hieraus ergeben sich für die Energiegewinnung drei Nachteile:

1. Nur das seltene Isotop ^{235}U trägt zur Energieerzeugung in der Uranmaschine bei; somit wird weniger als ein Prozent der im Uran vorhandenen Spaltungsenergie ausgenützt.

2. Die starke Neutronenabsorption des unwirksamen ^{238}U zwingt zu höchster Reinigung des Materials und wahrscheinlich zur Verwendung des schwer erhältlichen schweren Wasserstoffs als Bremssubstanz.

3. Wegen der Resonanzabsorption der Neutronen im ^{238}U kann selbst die Energie des ^{235}U nicht auf einmal bei sehr hoher Temperatur freigemacht werden; dadurch fällt die Verwendung als Sprengstoff praktisch weg.

Alle diese Schwierigkeiten liessen sich überwinden, wenn auch ^{238}U durch thermische Neutronen gespalten werden könnte. Es ist nun möglich, dass dies zwar nicht durch ein Neutron, aber durch zwei sukzessive angelagerte Neutronen geschieht. Das erste Neutron erzeugt das Isotop ^{239}U, das nach Hahn in 23 Minuten zerfällt. Dabei muss ^{239}Eka Re entstehen. Im folgenden wird die Wahrscheinlichkeit der Entstehung und der Spaltbarkeit dieses Kerns geprüft.

2. Die Erzeugung des Eka Re. Pro Spaltprozess entstehen $\chi' - \chi \frac{\sigma_U}{\sigma_2}$ Neutronen. Dabei ist χ die Zahl der pro im Uran absorbiertes thermisches Neutron entstehenden Neutronen, σ_U der gesamte effe

- 2 -

tive Wirkungsquerschnitt von normalem Uran für thermische Neutronen, σ_z der Wirkungsquerschnitt des Spaltprozesses allein. Setzt man $\frac{\sigma_U}{\sigma_z} = \frac{3,4}{2,0}$ und $\chi = 1,9$, so ist $\chi' = 3,23$ mit einem Fehler von 10-20 %. Arbeitet nun die Maschine stationär, so wird von diesen 3,2 Neutronen genau eines verwendet, um wieder einen Spaltprozess auszulösen. Von den übrigen 2,2 Neutronen verlässt ein Bruchteil die Maschine durch die Oberfläche, ein anderer Bruchteil wird in der Bremssubstanz absorbiert, der grösste Teil aber wird im Uran absorbiert und erzeugt dort den 23-Minuten-Körper, somit Eka Re.

Wir schätzen den Bruchteil ab, der durch die Oberfläche und in der Bremssubstanz verlorengeht. Die Maschine sei eine Kugel vom Radius R, von deren Volumen der Bruchteil α_U mit Uran, der Bruchteil α_S mit Streusubstanz erfüllt ist ($\alpha_U + \alpha_S = 1$). Die mittlere Neutronendichte sei im Uran ρ_U, in der Streusubstanz ρ_S. Dann ist die pro Sekunde absorbierte Neutronenmenge in der Streusubstanz

$$N_S = \frac{4\pi R^3}{3}\alpha_S |\nu_S| \rho_S$$

und im Uran

$$N_U = \frac{4\pi R^3}{3}\alpha_U |\nu_U| \rho_U (1 + \chi_w)$$

In der Klammer des Ausdrucks für gibt die 1 die thermischen, das χ_w die Resonanzneutronen an, die weggefangen werden. Die Dichte in der Nähe der Oberfläche genügt der Formel

$$\rho(r) = \rho_0 \frac{R}{r} \sin\left(\frac{R-r}{\ell}\right).$$

ℓ ist die Diffusionslänge des Materials, aus dem die äusserste Schicht der Kugel besteht. Pro Sekunde verlassen

$$N_0 = 4\pi R^2 D \left(\frac{\partial \rho}{\partial r}\right)_R = \frac{4\pi R^2 D \rho_0}{\ell} = 4\pi R^2 \ell |\nu| \rho_0$$

Neutronen die Oberfläche (auch D und ν beziehen sich auf das Material der äussersten Schicht). Man rechnet ungünstig für die

2a

~~SECRET~~

– 3 –

Einfangung im Uran, wenn man setzt $\rho_o = \rho_U = \frac{1}{3}\rho_s$. Man erhält so

$$\frac{N_o}{N_U} = \frac{3}{\alpha_U}\,\frac{l}{R}\,\frac{\nu}{\nu_U}\,\frac{1}{1+x_w} \quad ; \quad \frac{N_s}{N_U} = \frac{3\alpha_s}{\alpha_U}\,\frac{\nu_s}{\nu_U}\,\frac{1}{1+x_w} \tag{1}$$

Diese beiden Grössen sind in der Tabelle für verschiedene Maschinen und die nach den bisherigen Rechnungen jeweils günstigsten Apparatdimensionen überschlagsweise abgeschätzt unter der Annahme, dass die äusserste Schicht aus Streusubstanz besteht. Nur der Wert N_s/N_U für die Oxyd-H_2O-Maschine, der bei der Abschätzung am grössten herauskam, wurde durch strenge Integration aus einer von Herrn Höcker berechneten Maschine ermittelt.

Tabelle: Grössen aus Gl. (1)

Streusubstanz:	H_2O		D_2O	C
Zustand des Urans:	Metall	Oxyd	Metall	Metall
N_o/N_U :	0,07	0,09	0,06	0,07
N_s/N_U :	0,13	0,22	0,08	0,2

Durch einen Spaltprozess entstehen

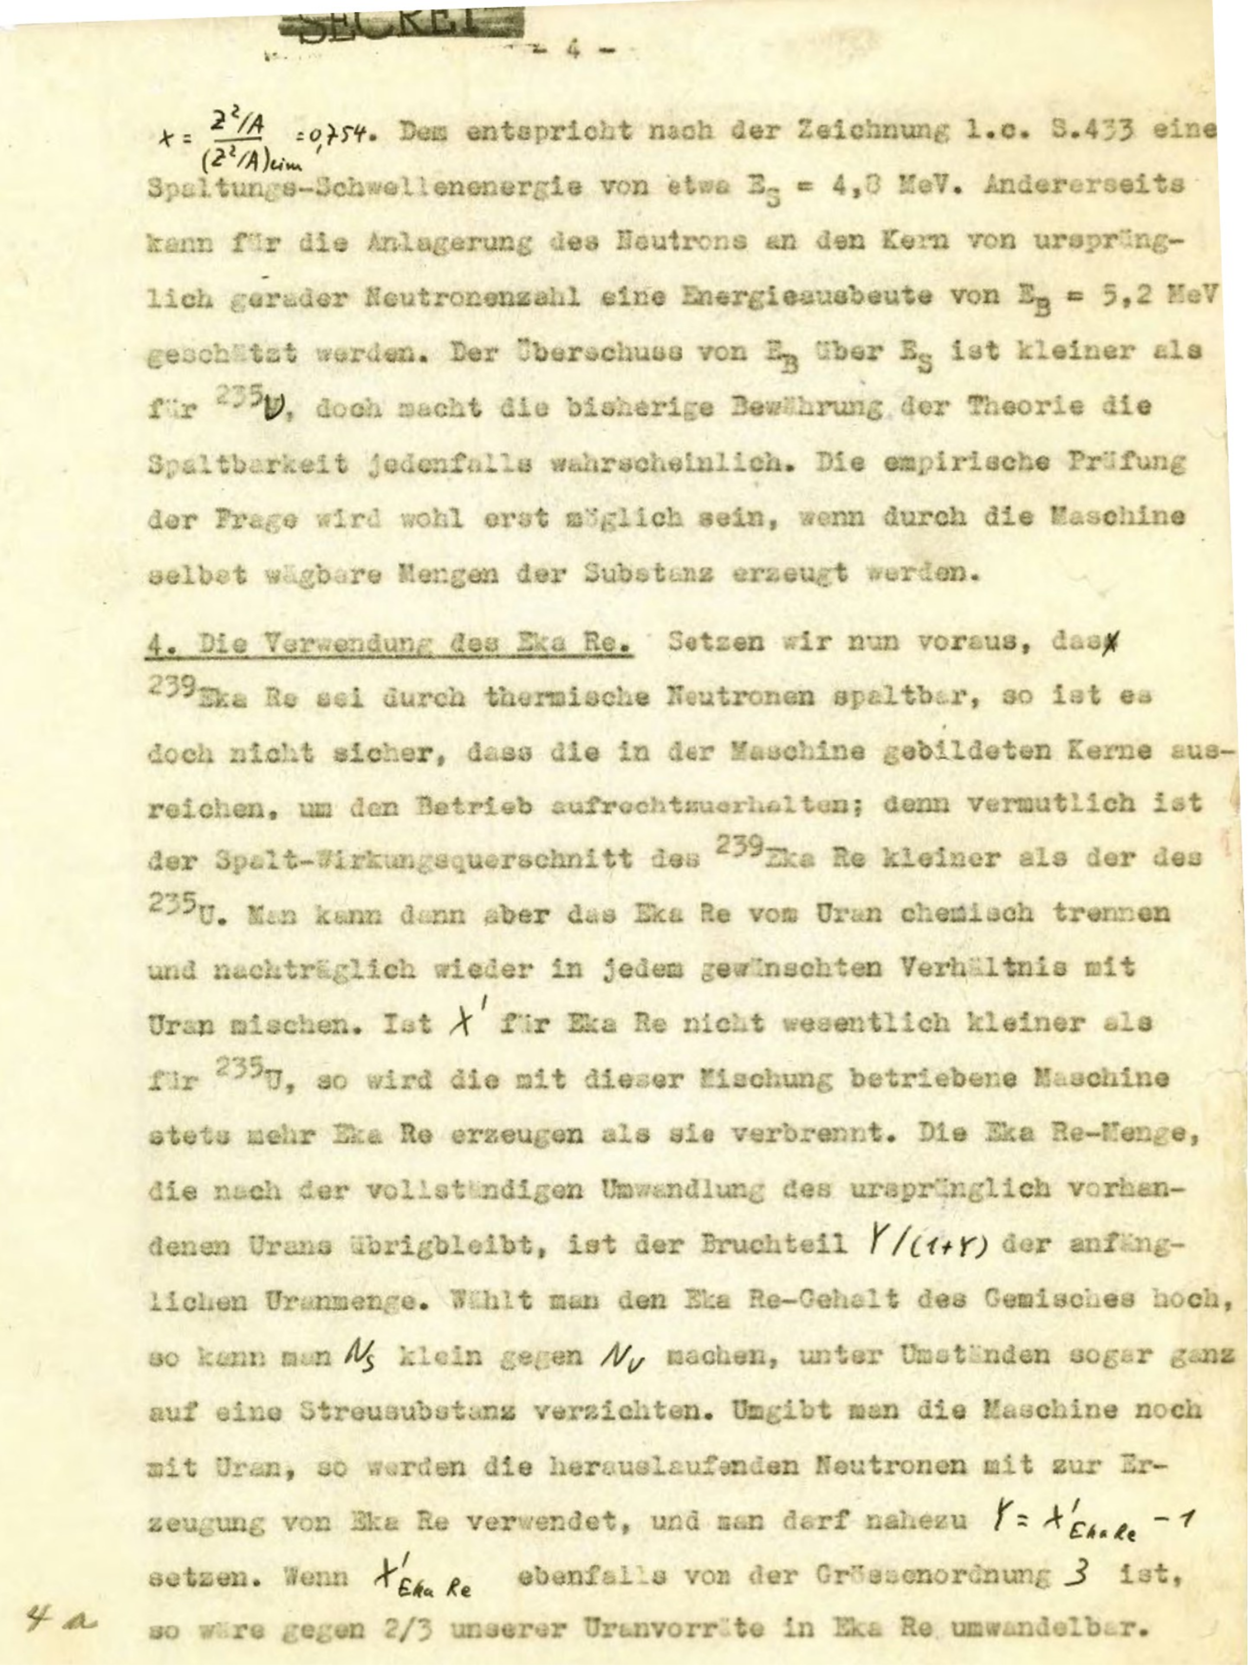
$$\gamma = \frac{x'}{1+\frac{N_o}{N_U}+\frac{N_s}{N_U}} - 1 \gtrsim 1{,}5 \tag{2}$$

Eka Re-Kerne. Damit wenigstens ein Eka Re-Kern pro Spaltung entsteht, muss $\frac{N_o}{N_U} + \frac{N_s}{N_U} < 0{,}6$ sein, was stets erfüllt ist.

3. Die Spaltbarkeit des Eka Re. Da kein strahlendes Folgeprodukt des 23-Minuten-Körpers beobachtet ist, ist es sehr wahrscheinlich, dass ^{239}Eka Re ein sehr langlebiger Körper ist, der vermutlich durch α-Zerfall in ^{235}Pa übergeht und so zur Actiniumreihe führt. Ob er durch thermische Neutronen spaltbar ist, kann vorläufig nur nach der Theorie von Bohr und Wheeler abgeschätzt werden. Für den durch Neutronenanlagerung aus ihm hervorgehenden Kern $^{240}_{93}$Eka Re ist die charakteristische Grösse

3 a

Figure D.339: Carl Friedrich von Weizsäcker's July 1940 report explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-59].



~~SECRET~~

- 4 -

$x = \frac{Z^2/A}{(Z^2/A)_{lim}} = 0{,}754$. Dem entspricht nach der Zeichnung l.c. S.433 eine Spaltungs-Schwellenenergie von etwa E_S = 4,8 MeV. Andererseits kann für die Anlagerung des Neutrons an den Kern von ursprünglich gerader Neutronenzahl eine Energieausbeute von E_B = 5,2 MeV geschätzt werden. Der Überschuss von E_B über E_S ist kleiner als für ^{235}U, doch macht die bisherige Bewährung der Theorie die Spaltbarkeit jedenfalls wahrscheinlich. Die empirische Prüfung der Frage wird wohl erst möglich sein, wenn durch die Maschine selbst wägbare Mengen der Substanz erzeugt werden.

4. Die Verwendung des Eka Re. Setzen wir nun voraus, das ^{239}Eka Re sei durch thermische Neutronen spaltbar, so ist es doch nicht sicher, dass die in der Maschine gebildeten Kerne ausreichen, um den Betrieb aufrechtzuerhalten; denn vermutlich ist der Spalt-Wirkungsquerschnitt des ^{239}Eka Re kleiner als der des ^{235}U. Man kann dann aber das Eka Re vom Uran chemisch trennen und nachträglich wieder in jedem gewünschten Verhältnis mit Uran mischen. Ist x' für Eka Re nicht wesentlich kleiner als für ^{235}U, so wird die mit dieser Mischung betriebene Maschine stets mehr Eka Re erzeugen als sie verbrennt. Die Eka Re-Menge, die nach der vollständigen Umwandlung des ursprünglich vorhandenen Urans übrigbleibt, ist der Bruchteil $Y/(1+Y)$ der anfänglichen Uranmenge. Wählt man den Eka Re-Gehalt des Gemisches hoch, so kann man N_S klein gegen N_U machen, unter Umständen sogar ganz auf eine Streusubstanz verzichten. Umgibt man die Maschine noch mit Uran, so werden die herauslaufenden Neutronen mit zur Erzeugung von Eka Re verwendet, und man darf nahezu $Y = x'_{Eka\,Re} - 1$ setzen. Wenn $x'_{Eka\,Re}$ ebenfalls von der Grössenordnung 3 ist, so wäre gegen 2/3 unserer Uranvorräte in Eka Re umwandelbar.

Energieerzeugung aus dem Uranisotop der Masse 238 und anderen schweren Elementen.

(Herstellung und Verwendung des Elements 94)

Bekanntlich ist seit der Entdeckung der Spaltung des Urankerns durch langsame Neutronen (Hahn und Straßmann, Naturwiss.27, 11,1939) die Erzeugung von Energie aus Kernreaktionen in greifbare Nähe gerückt worden. Es zeigte sich nämlich, (Dodé,v.Halban, Joliot, Kowarski, C.R.Acad.Sci.Paris 208, 995, 1939) daß beim Spaltprozess neue Neutronen entstehen, und man vermutete sofort, daß der ganze Vorgang nach Art einer Kettenreaktion geleitet werden könnte (z.B. S. Flügge, Naturwiss. 27, 402, 1939). Inzwischen ist durch den Anmelder gezeigt worden, wie diese autokatalytische Verbrennung des Urans oder einer seiner chemischen Verbindungen praktisch durchgeführt werden kann. Die Wirkungsweise einer solchen "Uranmaschine", wie eine solche Anordnung genannt werde, ist Gegenstand einer anderen Patentschrift. Das Prinzip ist kurz folgendes:

Theoretisch (Bohr und Wheeler, Phys. Rev. 56, 426, 1939) und experimentell (Nier und Mitarbeiter, Phys. Rev. 57, 546,1940) wurde gezeigt, daß nur das seltene Uranisotop ^{235}U durch thermische Neutronen gespalten wird. Das häufige Isotop ^{238}U (Häufigkeit größer als 99 %) trägt nichts zur Spaltung bei, vielmehr absorbiert es in hohem Maße die schnellen Neutronen, die bei der Spaltung von ^{235}U entstehen, noch ehe sie thermisch geworden sind. Es ist deswegen notwendig, die entstehenden schnellen Neutronen in anderen Substanzen (z.B. Paraffin, Deuteriumoxyd, Wasser etc.) zu verlangsamen, und dann zurück in das Uran zu leiten. Man kann leicht zeigen, daß es hierzu nicht genügt, (jedenfalls nicht immer) Uran und Bremssubstanz einfach zu mischen. Vielmehr müssen ganz genau definierte und angebbare Mengen beider Substanzen diskontinuierlich, z.B. schichtenweise in Ebenen oder Kugelschalen nach ganz bestimmten Regeln verteilt werden, damit eine effektive Neutronenvermehrung erzielt wird. Eine solche "Uranmaschine" wird, wie gesagt, an anderer Stelle genau beschrieben.

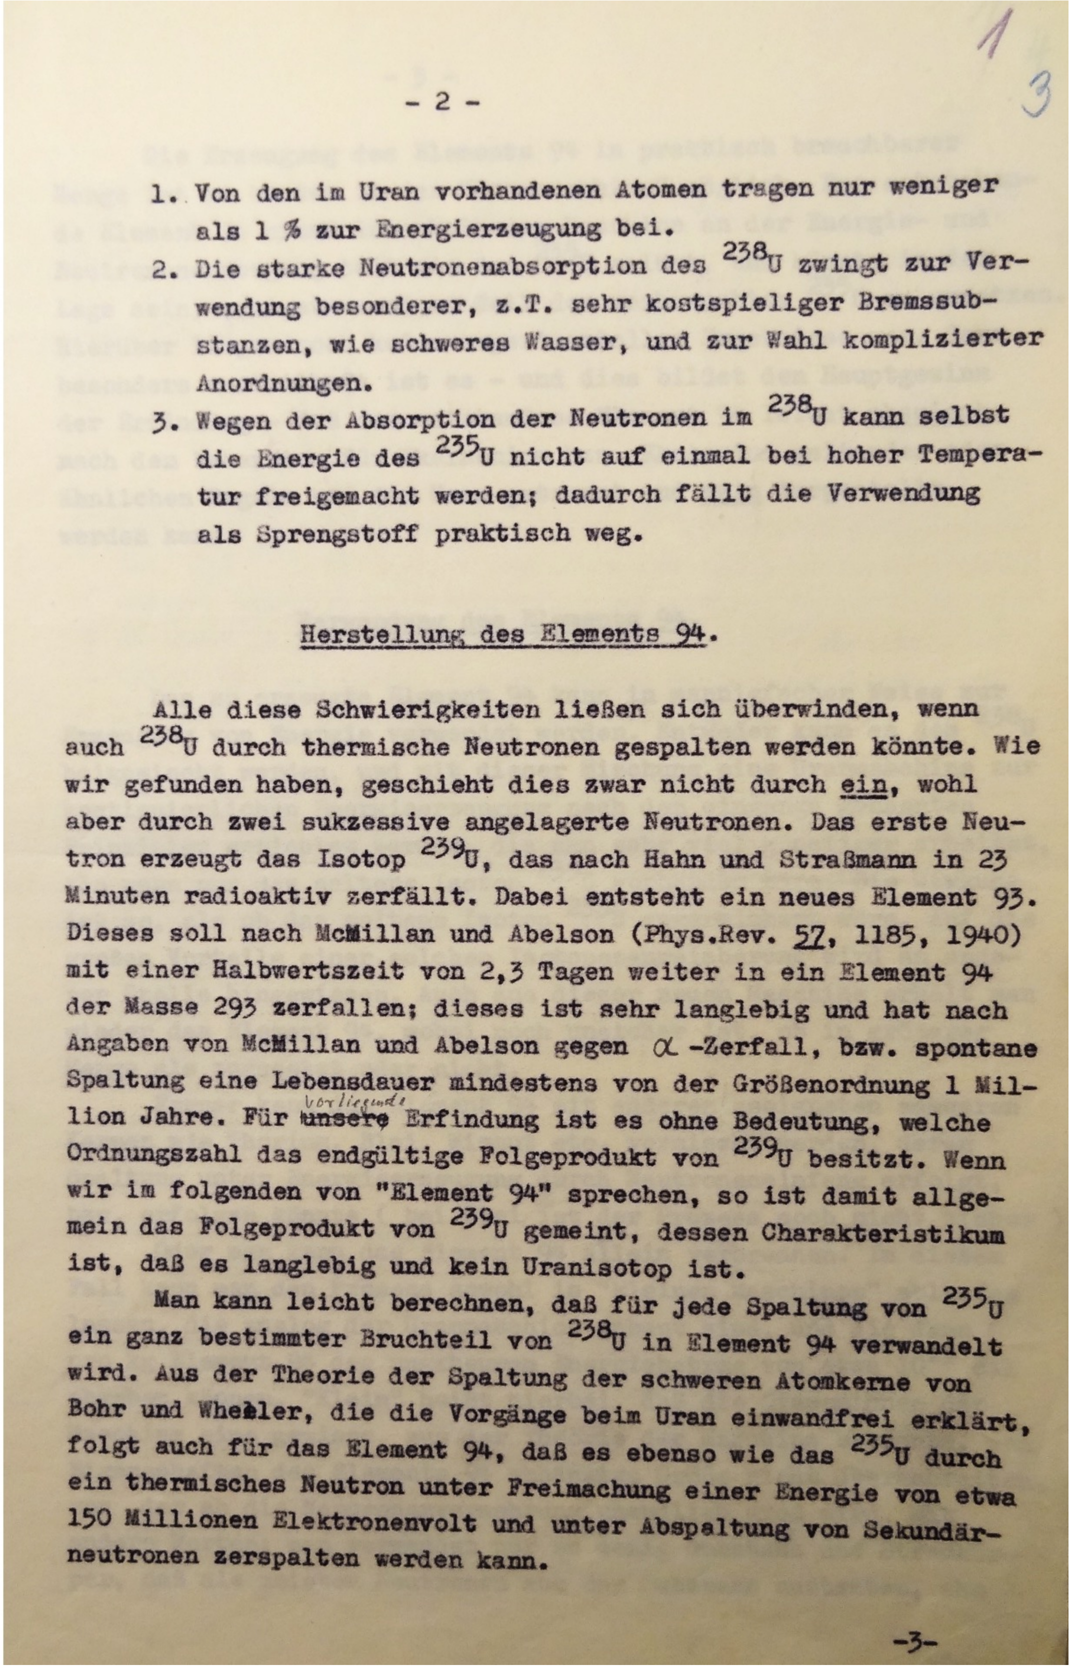
Aus der Tatsache, daß das häufige ^{238}U nicht an der Spaltung teilnimmt, ergeben sich für die Uranmaschine folgende Nachteile:

Anlage zu Bb. Nr. 116/41g

-2-

Figure D.344: Carl Friedrich von Weizsäcker's 11 June 1941 patent application on breeding plutonium-239 and using it to make fission bombs or fission reactors [AMPG 7314, KWIP 7, Folder 4 Pu].

AMPG 7314, KWIP 7, Folder 4 Pu



1. Von den im Uran vorhandenen Atomen tragen nur weniger als 1 % zur Energierzeugung bei.
2. Die starke Neutronenabsorption des ^{238}U zwingt zur Verwendung besonderer, z.T. sehr kostspieliger Bremssubstanzen, wie schweres Wasser, und zur Wahl komplizierter Anordnungen.
3. Wegen der Absorption der Neutronen im ^{238}U kann selbst die Energie des ^{235}U nicht auf einmal bei hoher Temperatur freigemacht werden; dadurch fällt die Verwendung als Sprengstoff praktisch weg.

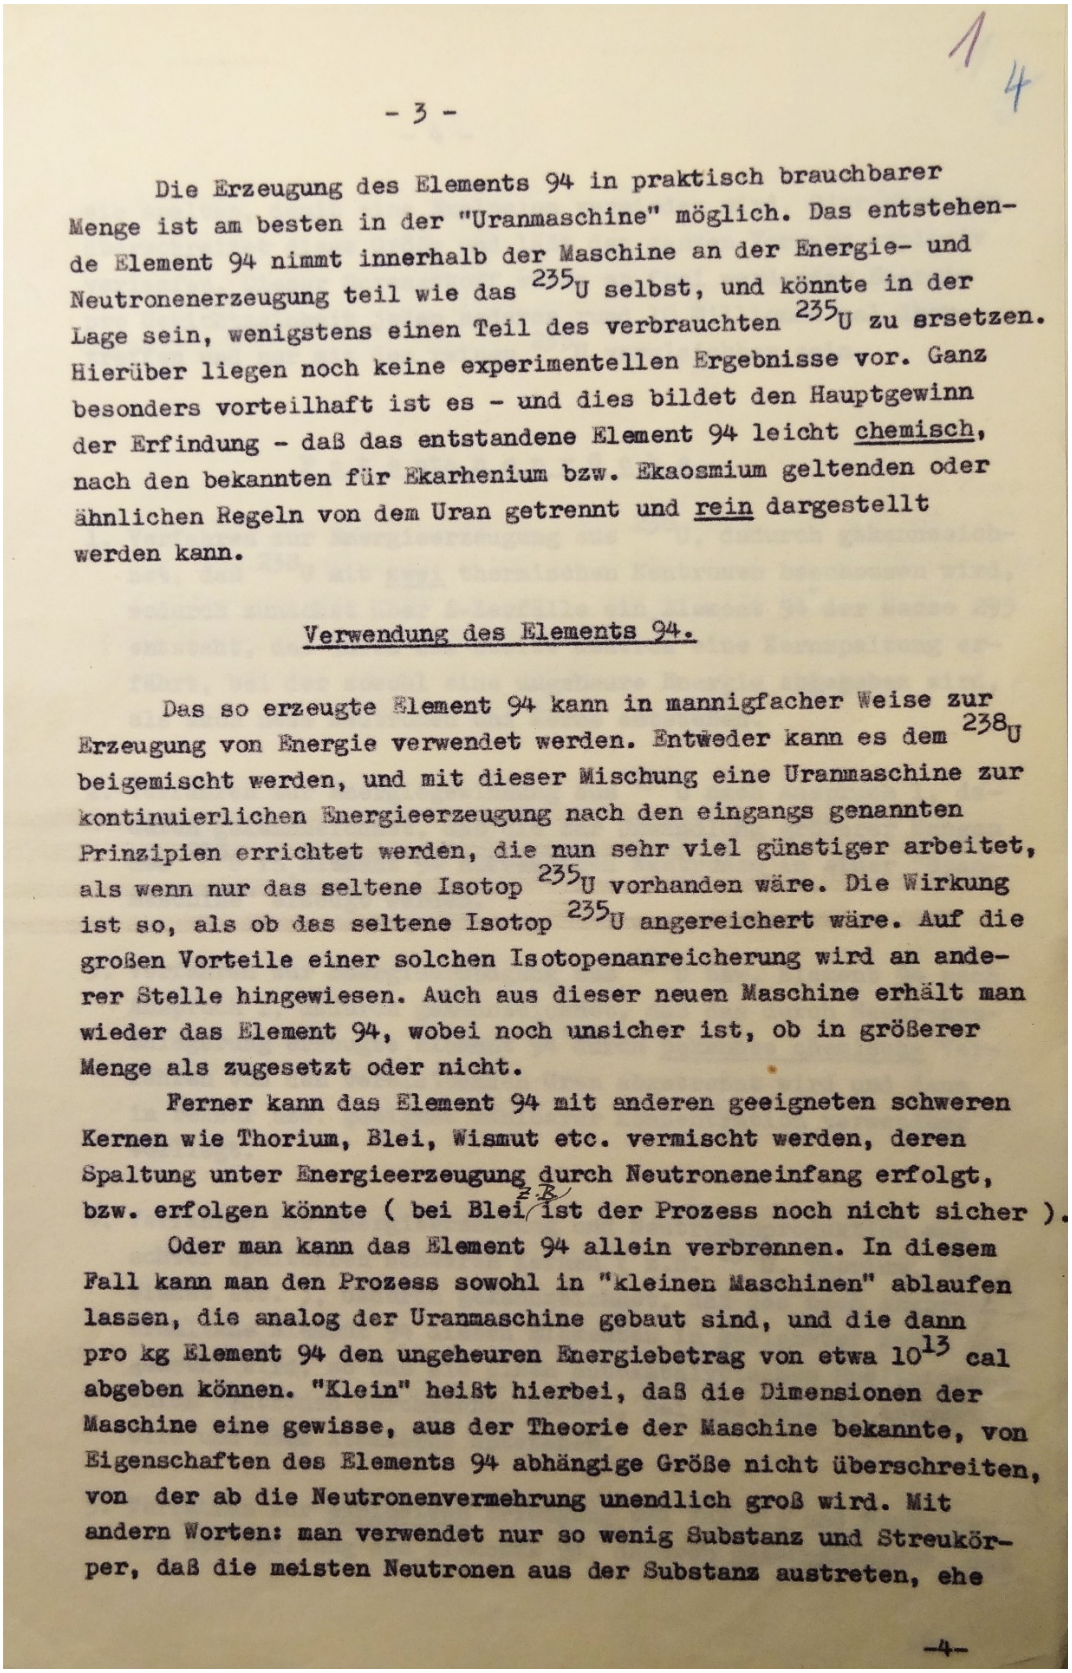
Herstellung des Elements 94.

Alle diese Schwierigkeiten ließen sich überwinden, wenn auch ^{238}U durch thermische Neutronen gespalten werden könnte. Wie wir gefunden haben, geschieht dies zwar nicht durch ein, wohl aber durch zwei sukzessive angelagerte Neutronen. Das erste Neutron erzeugt das Isotop ^{239}U, das nach Hahn und Straßmann in 23 Minuten radioaktiv zerfällt. Dabei entsteht ein neues Element 93. Dieses soll nach McMillan und Abelson (Phys.Rev. 57, 1185, 1940) mit einer Halbwertszeit von 2,3 Tagen weiter in ein Element 94 der Masse 293 zerfallen; dieses ist sehr langlebig und hat nach Angaben von McMillan und Abelson gegen α-Zerfall, bzw. spontane Spaltung eine Lebensdauer mindestens von der Größenordnung 1 Million Jahre. Für ~~unsere~~ vorliegende Erfindung ist es ohne Bedeutung, welche Ordnungszahl das endgültige Folgeprodukt von ^{239}U besitzt. Wenn wir im folgenden von "Element 94" sprechen, so ist damit allgemein das Folgeprodukt von ^{239}U gemeint, dessen Charakteristikum ist, daß es langlebig und kein Uranisotop ist.

Man kann leicht berechnen, daß für jede Spaltung von ^{235}U ein ganz bestimmter Bruchteil von ^{238}U in Element 94 verwandelt wird. Aus der Theorie der Spaltung der schweren Atomkerne von Bohr und Wheeler, die die Vorgänge beim Uran einwandfrei erklärt, folgt auch für das Element 94, daß es ebenso wie das ^{235}U durch ein thermisches Neutron unter Freimachung einer Energie von etwa 150 Millionen Elektronenvolt und unter Abspaltung von Sekundärneutronen zerspalten werden kann.

Figure D.345: Carl Friedrich von Weizsäcker's 11 June 1941 patent application on breeding plutonium-239 and using it to make fission bombs or fission reactors [AMPG 7314, KWIP 7, Folder 4 Pu].

AMPG 7314, KWIP 7, Folder 4 Pu



1

4

- 3 -

Die Erzeugung des Elements 94 in praktisch brauchbarer Menge ist am besten in der "Uranmaschine" möglich. Das entstehende Element 94 nimmt innerhalb der Maschine an der Energie- und Neutronenerzeugung teil wie das ^{235}U selbst, und könnte in der Lage sein, wenigstens einen Teil des verbrauchten ^{235}U zu ersetzen. Hierüber liegen noch keine experimentellen Ergebnisse vor. Ganz besonders vorteilhaft ist es - und dies bildet den Hauptgewinn der Erfindung - daß das entstandene Element 94 leicht chemisch, nach den bekannten für Ekarhenium bzw. Ekaosmium geltenden oder ähnlichen Regeln von dem Uran getrennt und rein dargestellt werden kann.

Verwendung des Elements 94.

Das so erzeugte Element 94 kann in mannigfacher Weise zur Erzeugung von Energie verwendet werden. Entweder kann es dem ^{238}U beigemischt werden, und mit dieser Mischung eine Uranmaschine zur kontinuierlichen Energieerzeugung nach den eingangs genannten Prinzipien errichtet werden, die nun sehr viel günstiger arbeitet, als wenn nur das seltene Isotop ^{235}U vorhanden wäre. Die Wirkung ist so, als ob das seltene Isotop ^{235}U angereichert wäre. Auf die großen Vorteile einer solchen Isotopenanreicherung wird an anderer Stelle hingewiesen. Auch aus dieser neuen Maschine erhält man wieder das Element 94, wobei noch unsicher ist, ob in größerer Menge als zugesetzt oder nicht.

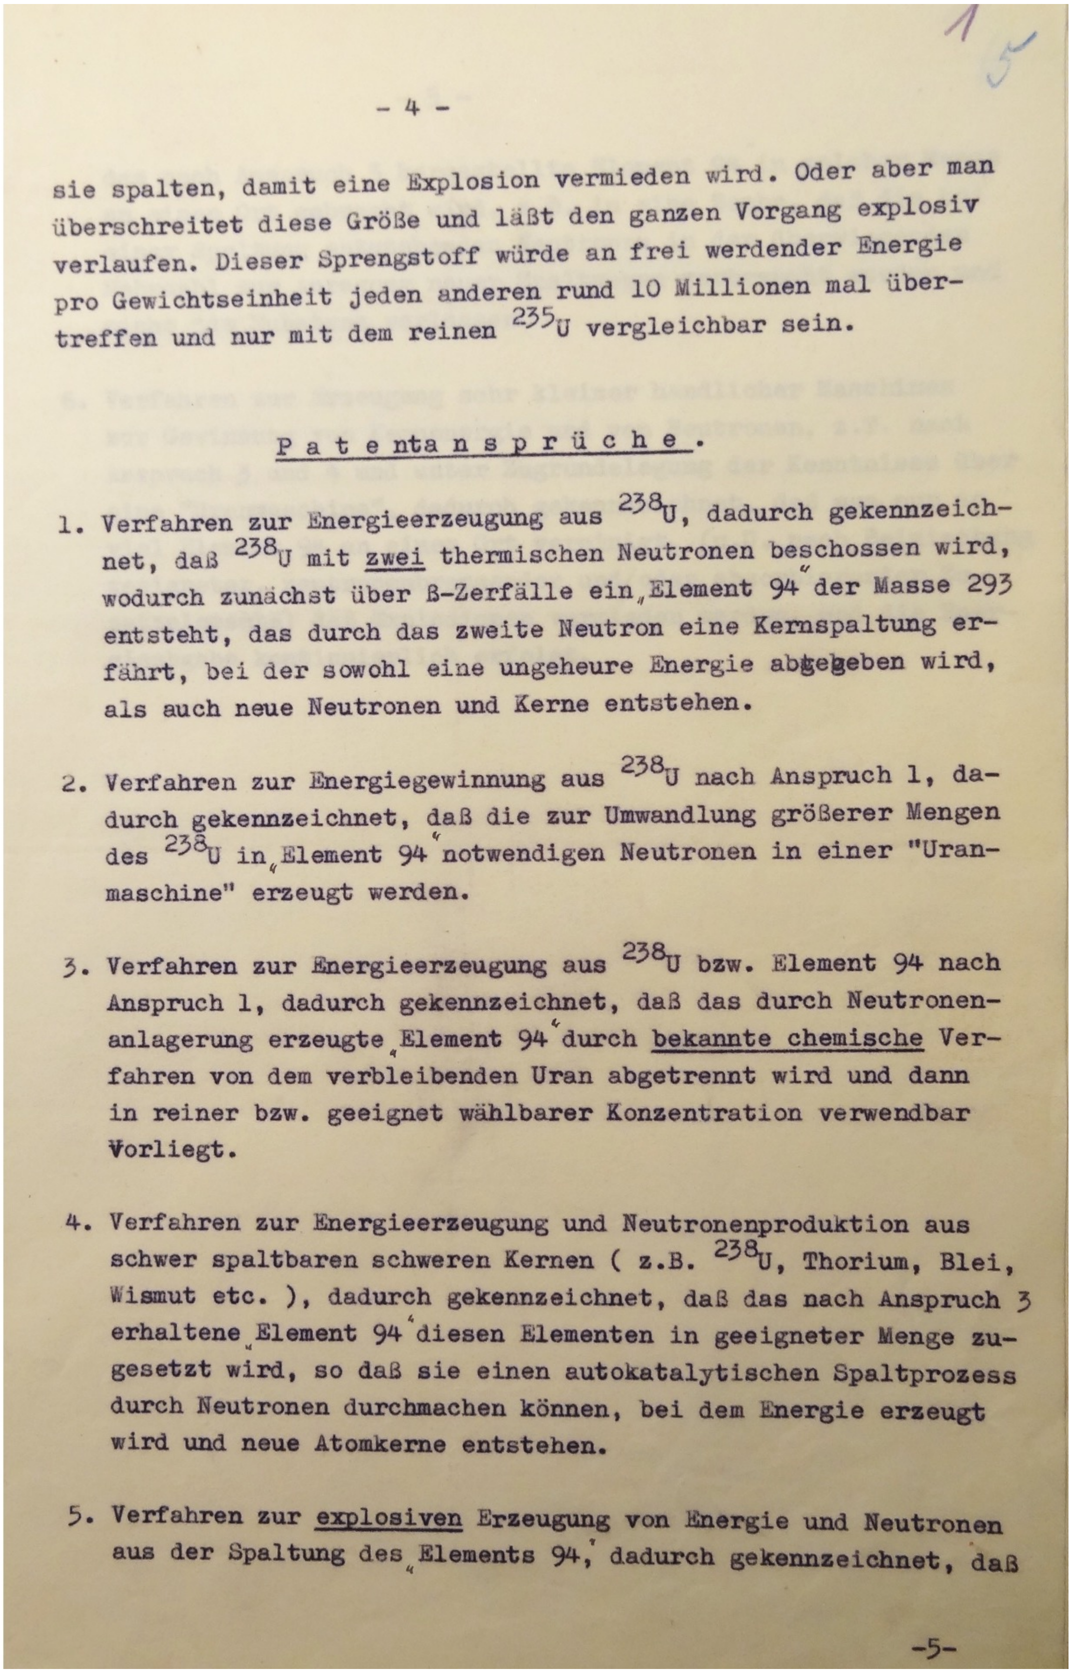
Ferner kann das Element 94 mit anderen geeigneten schweren Kernen wie Thorium, Blei, Wismut etc. vermischt werden, deren Spaltung unter Energieerzeugung durch Neutroneneinfang erfolgt, bzw. erfolgen könnte (bei Blei z.B. ist der Prozess noch nicht sicher).

Oder man kann das Element 94 allein verbrennen. In diesem Fall kann man den Prozess sowohl in "kleinen Maschinen" ablaufen lassen, die analog der Uranmaschine gebaut sind, und die dann pro kg Element 94 den ungeheuren Energiebetrag von etwa 10^{13} cal abgeben können. "Klein" heißt hierbei, daß die Dimensionen der Maschine eine gewisse, aus der Theorie der Maschine bekannte, von Eigenschaften des Elements 94 abhängige Größe nicht überschreiten, von der ab die Neutronenvermehrung unendlich groß wird. Mit andern Worten: man verwendet nur so wenig Substanz und Streukörper, daß die meisten Neutronen aus der Substanz austreten, ehe

-4-

Figure D.346: Carl Friedrich von Weizsäcker's 11 June 1941 patent application on breeding plutonium-239 and using it to make fission bombs or fission reactors [AMPG 7314, KWIP 7, Folder 4 Pu].

AMPG 7314, KWIP 7, Folder 4 Pu



1 5

sie spalten, damit eine Explosion vermieden wird. Oder aber man überschreitet diese Größe und läßt den ganzen Vorgang explosiv verlaufen. Dieser Sprengstoff würde an frei werdender Energie pro Gewichtseinheit jeden anderen rund 10 Millionen mal übertreffen und nur mit dem reinen ^{235}U vergleichbar sein.

Patentansprüche.

1. Verfahren zur Energieerzeugung aus ^{238}U, dadurch gekennzeichnet, daß ^{238}U mit zwei thermischen Neutronen beschossen wird, wodurch zunächst über ß-Zerfälle ein „Element 94“ der Masse 293 entsteht, das durch das zweite Neutron eine Kernspaltung erfährt, bei der sowohl eine ungeheure Energie abgegeben wird, als auch neue Neutronen und Kerne entstehen.

2. Verfahren zur Energiegewinnung aus ^{238}U nach Anspruch 1, dadurch gekennzeichnet, daß die zur Umwandlung größerer Mengen des ^{238}U in „Element 94“ notwendigen Neutronen in einer "Uranmaschine" erzeugt werden.

3. Verfahren zur Energieerzeugung aus ^{238}U bzw. Element 94 nach Anspruch 1, dadurch gekennzeichnet, daß das durch Neutronenanlagerung erzeugte „Element 94“ durch bekannte chemische Verfahren von dem verbleibenden Uran abgetrennt wird und dann in reiner bzw. geeignet wählbarer Konzentration verwendbar vorliegt.

4. Verfahren zur Energieerzeugung und Neutronenproduktion aus schwer spaltbaren schweren Kernen (z.B. ^{238}U, Thorium, Blei, Wismut etc.), dadurch gekennzeichnet, daß das nach Anspruch 3 erhaltene „Element 94“ diesen Elementen in geeigneter Menge zugesetzt wird, so daß sie einen autokatalytischen Spaltprozess durch Neutronen durchmachen können, bei dem Energie erzeugt wird und neue Atomkerne entstehen.

5. Verfahren zur explosiven Erzeugung von Energie und Neutronen aus der Spaltung des „Elements 94“, dadurch gekennzeichnet, daß

G-94. Fritz Houtermans. Zur Frage der Auslösung von Kern-Kettenreaktionen. August 1941. Same as report G-267.

[See document photos on pp. 3816–3823.]

[U.S.-created English abstract:] Brief summary covering the following aspects: Analysis of the factors which prevent nuclear fission. Possibility of fission with fast neutrons. Fission with thermal neutrons. Need for enrichment of U^{235}. Difficulty and expense of isotope separation. Moderators: D_2O, beryllium or beryllium oxide, carbon. Effect of temperature on absorption of thermal neutrons. Possibility of chain reaction with natural isotope mixtures of U at low temperatures. Calculations for critical mass. Although difficulty of getting economical power from lower temperature pile, there are other gains possible, e.g., radioisotopes; formation of 239 isotope, which is also subject to fission by thermal neutrons.

[Excerpts:]

[I.] Kernspaltung wurde bisher bekanntlich an den Atomkernen U^{238}, U^{235}, Th^{232}, Pa^{231} und Jo^{230} beobachtet. Kernspaltung kann durch geladene Teilchen (Protonen oder Deuteronen) einer Energie von etwa 5–6 MeV, γ-Quanten einer Energie der gleichen Größenordnung und durch Neutronen ausgelöst werden. [...]

[VII.] Vergleichen wir etwa die Neutronenergiebigkeit einer solchen Apparatur mit der besten bisherigen Neutronenquelle, einem Zyklotron, so zeigt sich leicht, daß eine solche Anlage mit einer Menge natürlichen Urangemischs von ca. 1 t der Leistung von etwa 10^4 bis 10^5 Zyklotrons entspricht. [...]

Denn bei allen denkbaren Apparaturen, die eine Kettenreaktion an isoliertem U^{235} gestatten, würde ja nur 1/139 der gesamten zur Verfügung stehenden Uranmenge als "Brennstoff" oder "Explosivesstoff" benutzt werden, während bei der Isotopentrennung auch für die unverwertbaren Mengen von U^{238} Energie aufgewandt werden muß.

[I.] Nuclear fission has been observed to date for the atomic nuclei U^{238}, U^{235}, Th^{232}, Pa^{231}, and Jo^{230}. Nuclear fission can be triggered by charged particles (protons or deuterons) with an energy of approximately 5–6 MeV, γ photons with an energy of the same magnitude, and by neutrons. [...]

[VII.] If, for example, we compare the neutron yield of such a reactor with the best previous neutron source, a cyclotron, it is easy to see that such a reactor, with a quantity of natural uranium mixture of about 1 ton, has a power of about 10^4 to 10^5 cyclotrons. [...]

For all conceivable devices that permit a chain reaction with purified U^{235}, only 1/139 of the total available uranium would be used as "fuel" or "explosive", while during isotope separation, impractical amounts of energy must also be expended on U^{238}.

Um diesen Punkt näher zu verstehen, müssen wir uns die Frage stellen, was aus denjenigen Neutronen wird, die bei der hier behandelten Kettenreaktion (U–schwere Bremssubstanz bei tiefer Temperatur) entstehen und nicht nach außen entweichen. Wir sehen oben, daß durch Ausschaltung der Neutronen-einfangung durch den Wasserstoff der einzig noch vorhandene Konkurrenzprozess, der in der Tat einen großen Teil der Neutronen schluckt, die Resonanzeinfangung des U^{238} ist. Bei dieser Resonanzeinfangung entsteht bekanntlich zunächst der 23 min-Körper, ein U^{239}_{92}, aus dem durch β-Zerfall zunächst Ek-Re^{239}_{93} entsteht, das wahrscheinlich selbst wieder β-aktiv ist und einem weiteren Körper der (4n+3)-Reihe liefert. [...] Im letzteren Falle aber muß das entstehende langlebige Isotop des Atomgewichts 239 selbst wieder Thermospaltung zeigen. [...] Jedes Neutron, das anstatt an U^{235} Spaltung zu bewirken von U^{238} eingefangen wird, schafft also einen neuen, durch thermische Neutronen spaltbaren Kern. Wir können daher eine Apparatur, die es ge-stattet, mit einem Energieumsatz an wägbaren Mengen U^{235} die Kettenreaktion ablaufen lassen, gleichzeitig als eine Isotopenumwandlungsapparatur ansehen. Der Vorteil gegenüber einer Isotopentrennungsapparatur ist aber der, daß das neugeschaffene Produkt, das ja eine Kernladung von 93 oder mehr hat, chemisch nicht mehr mit dem Uran identisch und daher mit gewöhnlichen chemischen Methoden abzutrennen ist. Da nun viel größere Mengen, nämlich das 139fache an U^{238} zur Verfügung stehen, so ist die Verwertbarmachung desselben als “Brennstoff” für eine Kettenreaktion ein für unsere Themenstellung viel wichtigerer Vorgang, als die Isotopentrennung, die bloß das U^{235} zu verwerten gestattet.

Für die Anregung zu dieser Arbeit und deren Ermöglichung danke ich Baron Manfred von Ardenne.

To understand this point in more detail, we have to ask ourselves what will become of the neutrons that are formed during the chain reaction (U-moderator at low temperature) and do not escape to the outside. We see above that by eliminating neutron capture by hydrogen, the only competitive process that actually absorbs a large portion of the neutrons is the resonance capture by U^{238}. This resonance capture is known to produce the 23-minute nucleus, U^{239}_{92}, for which β decay results in Ek-Re^{239}_{93}, which is likely to be β-active again and produces another (4n+3)-type body. [...] In the latter case, however, the resulting long-lived isotope of atomic weight 239 must again be fissionable by thermal neutrons. [...] Every neutron which, instead of fissioning U^{235}, is captured by U^{238} creates in this way a new nucleus, fissionable by thermal neutrons. We can therefore regard an apparatus that allows the chain reaction to proceed with an energy conversion of measurable amounts of U^{235} as an isotope conversion apparatus. The advantage over an isotope separation apparatus, however, is that the newly created product, which indeed has a nuclear charge of 93 or more, is no longer chemically identical to uranium and therefore can be purified by ordinary chemical methods. Since much larger quantities are available, namely 139 times more U^{238}, the utilization of it as “fuel” for a chain reaction is a much more important process for our topic than isotope separation, which only allows U^{235} to be used.

For suggesting this work and making it possible, I thank Baron Manfred von Ardenne.

Zur Frage der Auslösung von Kern-Kettenreaktionen.

von Fritz G. Houtermans

Mitteilung aus dem Laboratorium Manfred von Ardenne

Berlin-Lichterfelde-Ost

I. Einleitung. Allgemeine Gesichtspunkte.

Die Möglichkeit einer Energiegewinnung aus Reaktionen des Atomkernes ist, ähnlich wie bei der Ausnutzung chemischer Energie weitgehend abhängig von der Möglichkeit von Kettenreaktionen, d.h. davon, daß die zur Auslösung einer exothermen Reaktion nötige Aktivierungs-Energie durch die Reaktion selbst geliefert wird. Obwohl eine große Anzahl von exothermen Reaktionen der Atomkerne seit langem bekannt sind, mußte die Frage nach einer Möglichkeit von Kern-Kettenreaktionen bis vor einigen Jahren negativ beantwortet werden. Der Grund hierfür liegt darin, daß die "Aktivierungswärme", also die zur Auslösung einer Kettenreaktion nötige Energie nach dem damaligen Stand unserer Kenntnisse nur durch ein geladenes Teilchen oder ein γ-Quant auf den Kern übertragen werden.konnte. Da nun der Wirkungsquerschnitt des Kernes für die Auslösung von Kettenreaktionen nur etwa 10^{-8} des Wirkungsquerschnittes der Elektronenhülle des Atoms beträgt, ist die Wahrscheinlichkeit für die Auslösung einer Kettenreaktion durch ein geladenes Teilchen oder ein γ-Quant sehr klein. Sie beträgt selbst in den günstigsten bekannten Fällen von Kernresonanzen höchstens etwa 10^{-3} bis 10^{-} Die Ursache hierfür ist prinzipieller Natur. Sie liegt darin, daß ein geladenes Teilchen infolge der Coulomb-Kräfte in sehr erheblichem Maße Energie an die Hüllenelektronen des Atoms abgibt, und daher seine Energie im allgemeinen durch Ionisation der Atome viel eher verliert, als es einen zur Auslösung einer Kernreaktion führenden Kerntreffer macht. Das Gleiche gilt für γ-Quanten. Hier ist es die Energieabgabe durch den Compton-Effekt an die Hüllenelektronen, der die Wahrscheinlichkeit für eine Energiedissipation an der Atomhülle viel größer macht, als die Wahrscheinlichkeit für das Quant, vom Kern absorbiert zu werden und eine Kernreaktion auszulösen.

Erst durch die Entdeckung des Neutrons als eines Teilchens, das keine elektromagnetische Wechselwirkung mit den Elektronen der Atomhülle hat, war daher prinzipiell die Möglichkeit einer Kern-Kettenreaktion gegeben, denn ein Neutron kann im wesentlichen seine Energie nur durch Kerntreffer verlieren. Der Verfasser hat schon im Jahre 1932 in seiner Antrittsvorlesung an der Technischen Hochschule Berlin auf diese prinzipielle Möglichkeit hingewiesen und die Bedingung für die Bildung einer Kern-Kettenreaktion angegeben. Diese besteht darin, daß eine Kern-Kettenreaktion eintreten muß, sobald eine Reaktion bekannt ist, bei der mit der Wahrscheinlichkeit 1 an einem Kern durch ein Neutron ein weiteres Neutron ausgelöst wird, dessen Energie seinerseits imstande ist, an einem anderen Kern wieder ein Neutron auszulösen. Durch die Entdeckung der Spaltung schwerer Elemente durch Neutronen (Hahn und Strassmann 1938) ist nun bekanntlich inzwischen ein solcher Reaktionsmechanismus tatsächlich gefunden worden. Wesentlich ist hierbei nicht die Tatsache der sehr hohen freiwerdenden Reaktionsenergie in Höhe von etwa 180 MeV, sondern daß bei diesem Prozess neben den beiden großen Kerntrümmern, in die das schwere Atom aufspaltet, noch einige freie Neutronen entstehen, die ihrerseits wieder eine Kernspaltung hervorrufen können. Die Frage der Ausnutzung eines solchen Prozesses zur Auslösung von Kern-Kettenreaktionen ist also lediglich eine Frage möglichst maximaler Ausnutzung der entstehenden Neutronen. Der Verfasser hat im Zusammenhung mit anderen Problemstellungen, noch bevor die Kernspaltung bekannt war, eine Anzahl Überlegungen und Experimente angestellt, die als Ziel eine möglichst vollständige Ausnutzung entstehender Neutronen zugunsten einer bestimmten Kernreaktion gehabt haben. In vorliegender Mitteilung sollen diese Überlegungen speziell auf die Kernspaltung angewendet und verschiedene aus ihnen folgenden Möglichkeiten diskutiert werden.

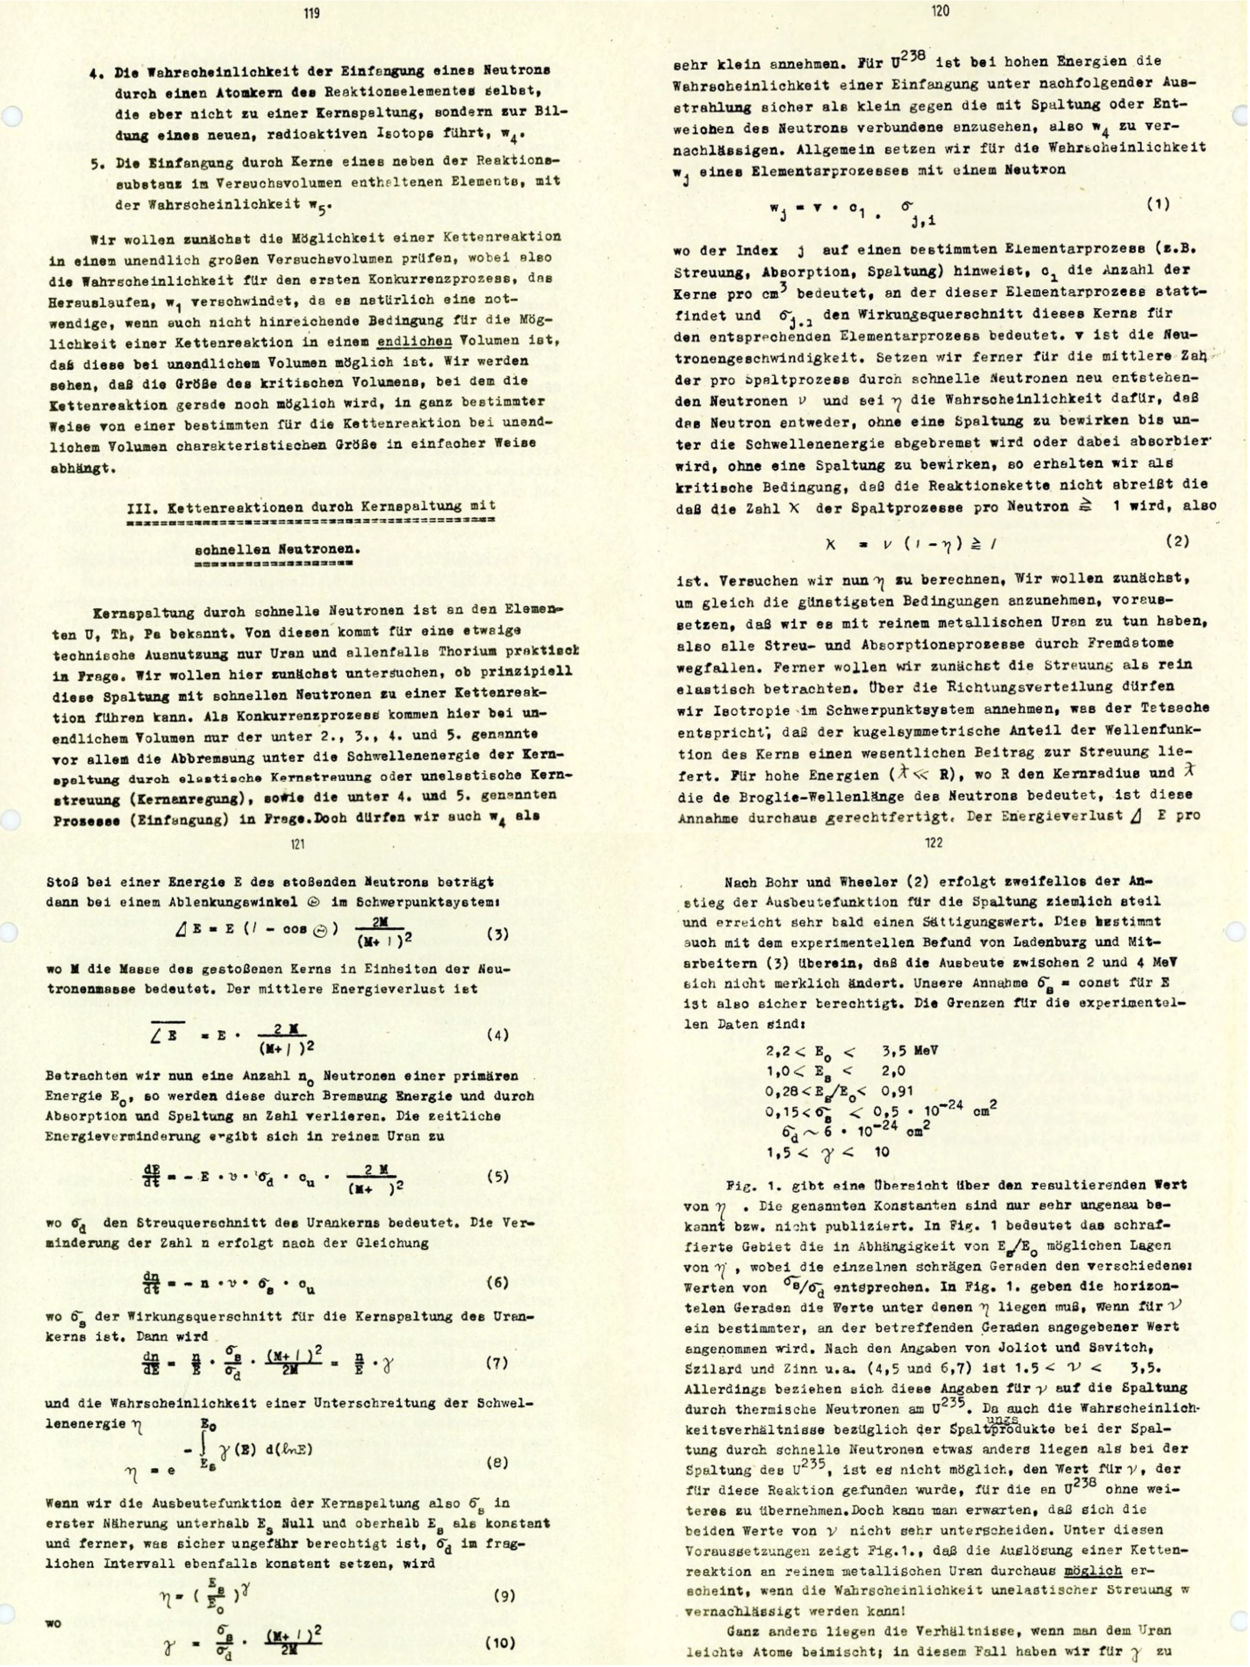
Kernspaltung wurde bisher bekanntlich an den Atomkernen U^{238}, U^{235}, Th^{232}, Pa^{231} und Jo^{230} beobachtet. Kernspaltung kann durch geladene Teilchen (Protonen oder Deuteronen) einer Energie von etwa 5-6 MeV, γ-Quanten einer Energie der gleichen Größenordnung und durch Neutronen ausgelöst werden. Nach dem oben Gesagten kommt für die Auslösung einer Kettenreaktion nur der letztgenannte Mechanismus, die Kernspaltung durch Neutronen in Frage. Die Zahl ν der bei jeder Kernspaltung frei werdenden Neutronen beträgt etwa 2 - 4. Die Auslösung einer Kettenreaktion hat jedoch zur Voraussetzung, daß alle Konkurrenzprozesse, durch die ein einmal entstandenes Neutron verloren gehen kann, ohne seinerseits eine Kernspaltung hervorzurufen, in hinreichendem Maße ausgeschaltet werden können.

II. Die Konkurrenzprozesse.

Es ist daher nötig, alle diese Konkurrenzprozesse und ihre Wahrscheinlichkeiten im einzelnen zu diskutieren. Die Konkurrenzprozesse, die zum Verlust eines Neutrons führen, ohne eine Kernspaltung zu bewirken, sind:

1. Das Herauslaufen eines Neutrons aus dem Versuchsvolumen, in dem die Kernspaltung hervorgerufen werden kann. Die Wahrscheinlichkeit hierfür soll mit w_1 bezeichnet werden.
2. Die Abbremsung eines Neutrons durch elastische Stöße, die zu einem solchen Energieverlust führt, daß die Energie nicht mehr ausreicht, um eine Kernspaltung zu bewirken; Wahrscheinlichkeit w_2.
3. Die Wahrscheinlichkeit eines solchen Energieverlustes eines Neutrons durch unelastische Stöße, w_3

Figure D.349: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].



4. Die Wahrscheinlichkeit der Einfangung eines Neutrons durch einen Atomkern des Reaktionselementes selbst, die aber nicht zu einer Kernspaltung, sondern zur Bildung eines neuen, radioaktiven Isotops führt, w_4.
5. Die Einfangung durch Kerne eines neben der Reaktionssubstanz im Versuchsvolumen enthaltenen Elements, mit der Wahrscheinlichkeit w_5.

Wir wollen zunächst die Möglichkeit einer Kettenreaktion in einem unendlich großen Versuchsvolumen prüfen, wobei also die Wahrscheinlichkeit für den ersten Konkurrenzprozess, das Herauslaufen, w_1 verschwindet, da es natürlich eine notwendige, wenn auch nicht hinreichende Bedingung für die Möglichkeit einer Kettenreaktion in einem endlichen Volumen ist, daß diese bei unendlichem Volumen möglich ist. Wir werden sehen, daß die Größe des kritischen Volumens, bei dem die Kettenreaktion gerade noch möglich wird, in ganz bestimmter Weise von einer bestimmten für die Kettenreaktion bei unendlichem Volumen charakteristischen Größe in einfacher Weise abhängt.

III. Kettenreaktionen durch Kernspaltung mit schnellen Neutronen.

Kernspaltung durch schnelle Neutronen ist an den Elementen U, Th, Pa bekannt. Von diesen kommt für eine etwaige technische Ausnutzung nur Uran und allenfalls Thorium praktisch in Frage. Wir wollen hier zunächst untersuchen, ob prinzipiell diese Spaltung mit schnellen Neutronen zu einer Kettenreaktion führen kann. Als Konkurrenzprozess kommen hier bei unendlichem Volumen nur der unter 2., 3., 4. und 5. genannte vor allem die Abbremsung unter die Schwellenenergie der Kernspaltung durch elastische Kernstreuung oder unelastische Kernstreuung (Kernanregung), sowie die unter 4. und 5. genannten Prozesse (Einfangung) in Frage. Doch dürfen wir auch w_4 als sehr klein annehmen. Für U^{238} ist bei hohen Energien die Wahrscheinlichkeit einer Einfangung unter nachfolgender Ausstrahlung sicher als klein gegen die mit Spaltung oder Entweichen des Neutrons verbundene anzusehen, also w_4 zu vernachlässigen.

Allgemein setzen wir für die Wahrscheinlichkeit w_j eines Elementarprozesses mit einem Neutron

$$w_j = v \cdot c_1 . \sigma_{j,i} \qquad (1)$$

wo der Index j auf einen bestimmten Elementarprozess (z.B. Streuung, Absorption, Spaltung) hinweist, c_1 die Anzahl der Kerne pro cm^3 bedeutet, an der dieser Elementarprozess stattfindet und $\sigma_{j.1}$ den Wirkungsquerschnitt dieses Kerns für den entsprechenden Elementarprozess bedeutet. v ist die Neutronengeschwindigkeit. Setzen wir ferner für die mittlere Zahl der pro Spaltprozess durch schnelle Neutronen neu entstehenden Neutronen ν und sei η die Wahrscheinlichkeit dafür, daß das Neutron entweder, ohne eine Spaltung zu bewirken bis unter die Schwellenenergie abgebremst wird oder dabei absorbiert wird, ohne eine Spaltung zu bewirken, so erhalten wir als kritische Bedingung, daß die Reaktionskette nicht abreißt die daß die Zahl χ der Spaltprozesse pro Neutron $\geqq$ 1 wird, also

$$\chi = \nu (1 - \eta) \geqq 1 \qquad (2)$$

ist. Versuchen wir nun η zu berechnen, Wir wollen zunächst, um gleich die günstigsten Bedingungen anzunehmen, vorauszusetzen, daß wir es mit reinem metallischen Uran zu tun haben, also alle Streu- und Absorptionsprozesse durch Fremdatome wegfallen. Ferner wollen wir zunächst die Streuung als rein elastisch betrachten. Über die Richtungsverteilung dürfen wir Isotropie im Schwerpunktsystem annehmen, was der Tatsache entspricht, daß der kugelsymmetrische Anteil der Wellenfunktion des Kerns einen wesentlichen Beitrag zur Streuung liefert. Für hohe Energien ($\lambdabar \ll R$), wo R den Kernradius und $\lambdabar$ die de Broglie-Wellenlänge des Neutrons bedeutet, ist diese Annahme durchaus gerechtfertigt. Der Energieverlust ΔE pro Stoß bei einer Energie E des stoßenden Neutrons beträgt dann bei einem Ablenkungswinkel Θ im Schwerpunktsystem:

$$\Delta E = E\,(1 - \cos \Theta)\,\frac{2M}{(M+1)^2} \qquad (3)$$

wo M die Masse des gestoßenen Kerns in Einheiten der Neutronenmasse bedeutet. Der mittlere Energieverlust ist

$$\overline{\Delta E} = E \cdot \frac{2M}{(M+1)^2} \qquad (4)$$

Betrachten wir nun eine Anzahl n_o Neutronen einer primären Energie E_o, so werden diese durch Bremsung Energie und durch Absorption und Spaltung an Zahl verlieren. Die zeitliche Energieverminderung ergibt sich in reinem Uran zu

$$\frac{dE}{dt} = - E \cdot v \cdot \sigma_d \cdot c_u \cdot \frac{2M}{(M+\ )^2} \qquad (5)$$

wo σ_d den Streuquerschnitt des Urankerns bedeutet. Die Verminderung der Zahl n erfolgt nach der Gleichung

$$\frac{dn}{dt} = - n \cdot v \cdot \sigma_s \cdot c_u \qquad (6)$$

wo σ_s der Wirkungsquerschnitt für die Kernspaltung des Urankerns ist. Dann wird

$$\frac{dn}{dE} = \frac{n}{E} \cdot \frac{\sigma_s}{\sigma_d} \cdot \frac{(M+1)^2}{2M} = \frac{n}{E} \cdot \gamma \qquad (7)$$

und die Wahrscheinlichkeit einer Unterschreitung der Schwellenenergie η

$$\eta = e^{-\int_{E_s}^{E_o} \gamma(E)\, d(\ln E)} \qquad (8)$$

Wenn wir die Ausbeutefunktion der Kernspaltung also σ_s in erster Näherung unterhalb E_s Null und oberhalb E_s als konstant und ferner, was sicher ungefähr berechtigt ist, σ_d im fraglichen Intervall ebenfalls konstant setzen, wird

$$\eta = \left(\frac{E_s}{E_o}\right)^{\gamma} \qquad (9)$$

wo

$$\gamma = \frac{\sigma_s}{\sigma_d} \cdot \frac{(M+1)^2}{2M} \qquad (10)$$

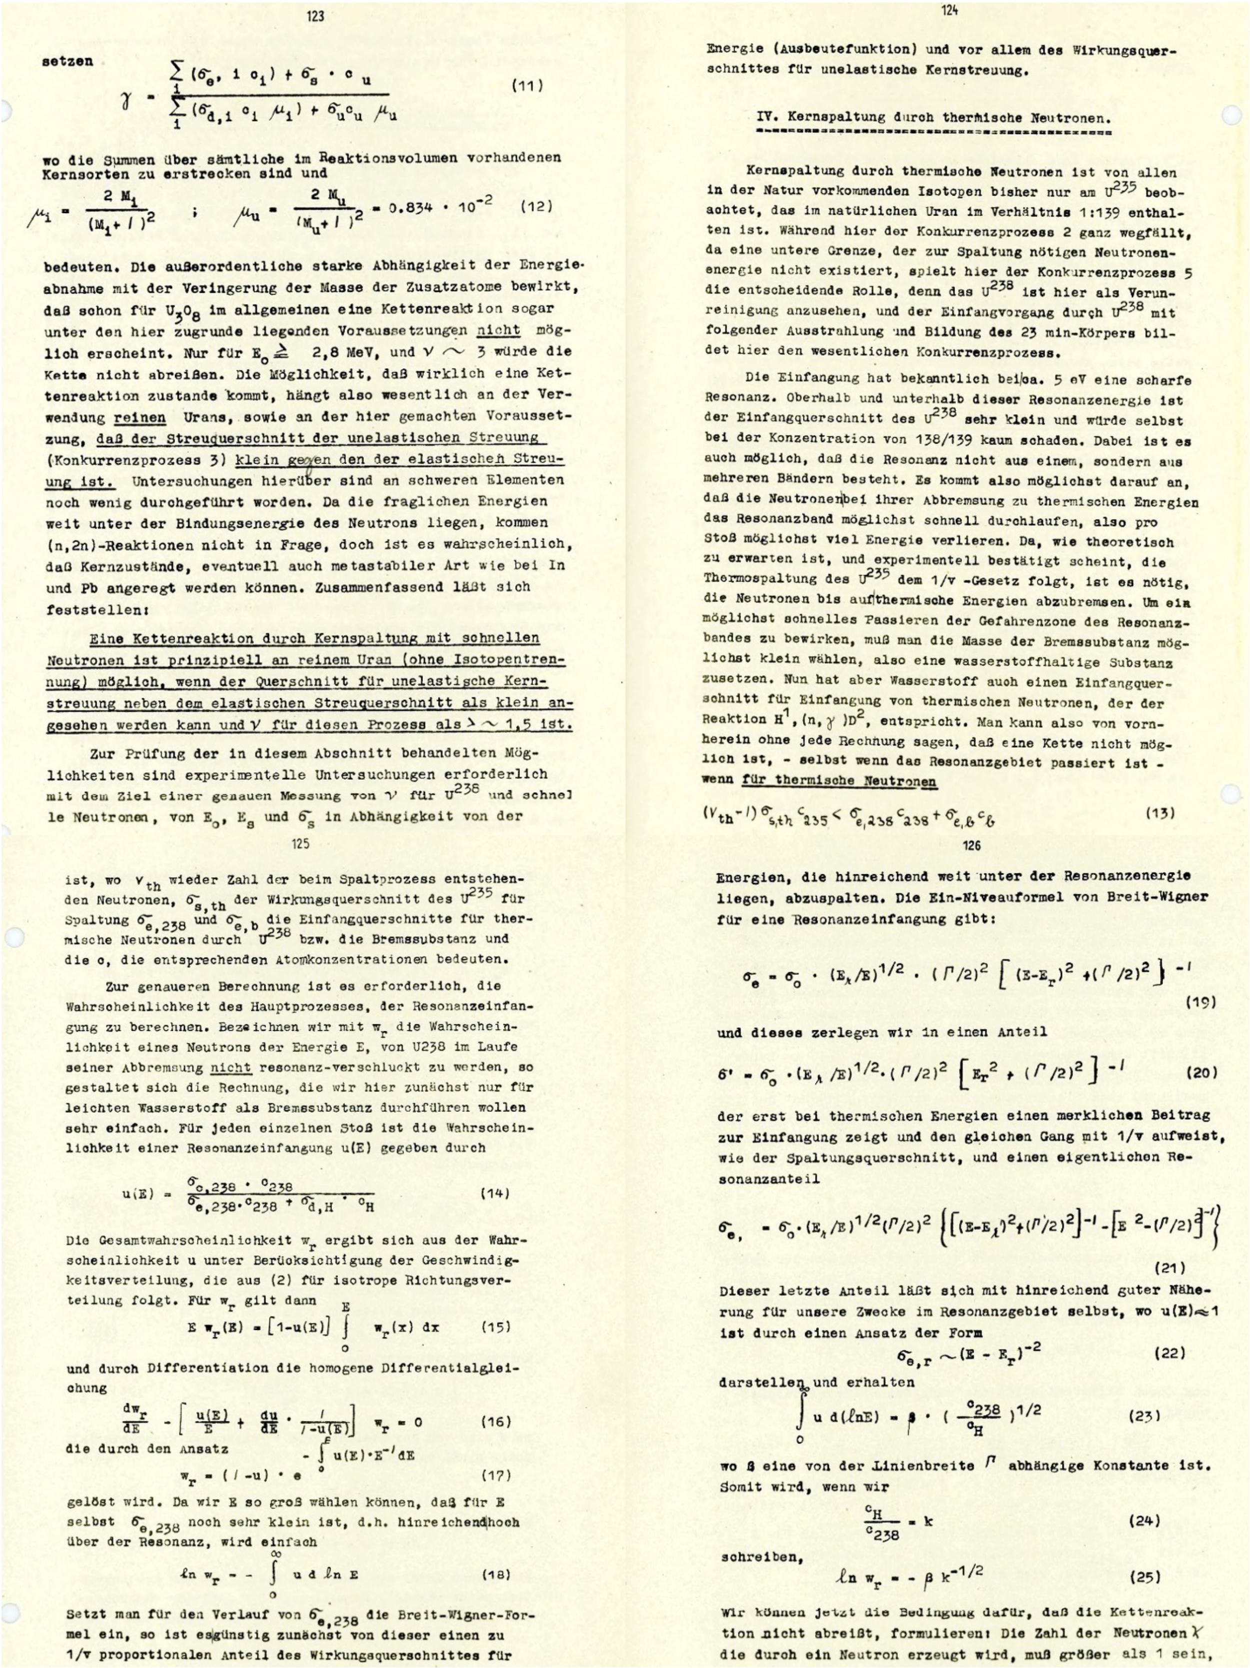
Nach Bohr und Wheeler (2) erfolgt zweifellos der Anstieg der Ausbeutefunktion für die Spaltung ziemlich steil und erreicht sehr bald einen Sättigungswert. Dies bestimmt auch mit dem experimentellen Befund von Ladenburg und Mitarbeitern (3) überein, daß die Ausbeute zwischen 2 und 4 MeV sich nicht merklich ändert. Unsere Annahme σ_s = const für E ist also sicher berechtigt. Die Grenzen für die experimentellen Daten sind:

$2{,}2 < E_o < 3{,}5$ MeV
$1{,}0 < E_s < 2{,}0$
$0{,}28 < E_s/E_o < 0{,}91$
$0{,}15 < \sigma_s < 0{,}5 \cdot 10^{-24}$ cm^2
$\sigma_d \sim 6 \cdot 10^{-24}$ cm^2
$1{,}5 < \gamma < 10$

Fig. 1. gibt eine Übersicht über den resultierenden Wert von η. Die genannten Konstanten sind nur sehr ungenau bekannt bzw. nicht publiziert. In Fig. 1 bedeutet das schraffierte Gebiet die in Abhängigkeit von E_s/E_o möglichen Lagen von η, wobei die einzelnen schrägen Geraden den verschiedenen Werten von σ_s/σ_d entsprechen. In Fig. 1. geben die horizontalen Geraden die Werte unter denen η liegen muß, wenn für ν ein bestimmter, an der betreffenden Geraden angegebener Wert angenommen wird. Nach den Angaben von Joliot und Savitch, Szilard und Zinn u.a. (4,5 und 6,7) ist $1.5 < \nu < 3{,}5$. Allerdings beziehen sich diese Angaben für ν auf die Spaltung durch thermische Neutronen am U^{235}. Da auch die Wahrscheinlichkeitsverhältnisse bezüglich der Spaltungsprodukte bei der Spaltung durch schnelle Neutronen etwas anders liegen als bei der Spaltung des U^{235}, ist es nicht möglich, den Wert für ν, der für diese Reaktion gefunden wurde, für die an U^{238} ohne weiteres zu übernehmen. Doch kann man erwarten, daß sich die beiden Werte von ν nicht sehr unterscheiden. Unter diesen Voraussetzungen zeigt Fig.1., daß die Auslösung einer Kettenreaktion an reinem metallischen Uran durchaus möglich erscheint, wenn die Wahrscheinlichkeit unelastischer Streuung w vernachlässigt werden kann!

Ganz anders liegen die Verhältnisse, wenn man dem Uran leichte Atome beimischt; in diesem Fall haben wir für γ zu

Figure D.350: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].



setzen

$$\gamma = \frac{\sum_i (\sigma_{e,i}\, c_i) + \sigma_s \cdot c_u}{\sum_i (\sigma_{d,i}\, c_i\, \mu_i) + \sigma_u c_u\, \mu_u} \tag{11}$$

wo die Summen über sämtliche im Reaktionsvolumen vorhandenen Kernsorten zu erstrecken sind und

$$\mu_i = \frac{2\, M_i}{(M_i + 1)^2} \quad ; \quad \mu_u = \frac{2\, M_u}{(M_u + 1)^2} = 0.834 \cdot 10^{-2} \tag{12}$$

bedeuten. Die außerordentliche starke Abhängigkeit der Energieabnahme mit der Veringerung der Masse der Zusatzatome bewirkt, daß schon für U_3O_8 im allgemeinen eine Kettenreaktion sogar unter den hier zugrunde liegenden Voraussetzungen nicht möglich erscheint. Nur für $E_o \geqq$ 2,8 MeV, und $\nu \sim 3$ würde die Kette nicht abreißen. Die Möglichkeit, daß wirklich eine Kettenreaktion zustande kommt, hängt also wesentlich an der Verwendung reinen Urans, sowie an der hier gemachten Voraussetzung, daß der Streuquerschnitt der unelastischen Streuung (Konkurrenzprozess 3) klein gegen den der elastischen Streuung ist. Untersuchungen hierüber sind an schweren Elementen noch wenig durchgeführt worden. Da die fraglichen Energien weit unter der Bindungsenergie des Neutrons liegen, kommen (n,2n)-Reaktionen nicht in Frage, doch ist es wahrscheinlich, daß Kernzustände, eventuell auch metastabiler Art wie bei In und Pb angeregt werden können. Zusammenfassend läßt sich feststellen:

Eine Kettenreaktion durch Kernspaltung mit schnellen Neutronen ist prinzipiell an reinem Uran (ohne Isotopentrennung) möglich, wenn der Querschnitt für unelastische Kernstreuung neben dem elastischen Streuquerschnitt als klein angesehen werden kann und ν für diesen Prozess als $\lambda \sim 1,5$ ist.

Zur Prüfung der in diesem Abschnitt behandelten Möglichkeiten sind experimentelle Untersuchungen erforderlich mit dem Ziel einer genauen Messung von ν für U^{238} und schnelle Neutronen, von E_o, E_s und σ_s in Abhängigkeit von der

Energie (Ausbeutefunktion) und vor allem des Wirkungsquerschnittes für unelastische Kernstreuung.

IV. Kernspaltung durch thermische Neutronen.

Kernspaltung durch thermische Neutronen ist von allen in der Natur vorkommenden Isotopen bisher nur am U^{235} beobachtet, das im natürlichen Uran im Verhältnis 1:139 enthalten ist. Während hier der Konkurrenzprozess 2 ganz wegfällt, da eine untere Grenze, der zur Spaltung nötigen Neutronenenergie nicht existiert, spielt hier der Konkurrenzprozess 5 die entscheidende Rolle, denn das U^{238} ist hier als Verunreinigung anzusehen, und der Einfangvorgang durch U^{238} mit folgender Ausstrahlung und Bildung des 23 min-Körpers bildet hier den wesentlichen Konkurrenzprozess.

Die Einfangung hat bekanntlich bei ca. 5 eV eine scharfe Resonanz. Oberhalb und unterhalb dieser Resonanzenergie ist der Einfangquerschnitt des U^{238} sehr klein und würde selbst bei der Konzentration von 138/139 kaum schaden. Dabei ist es auch möglich, daß die Resonanz nicht aus einem, sondern aus mehreren Bändern besteht. Es kommt also möglichst darauf an, daß die Neutronen bei ihrer Abbremsung zu thermischen Energien das Resonanzband möglichst schnell durchlaufen, also pro Stoß möglichst viel Energie verlieren. Da, wie theoretisch zu erwarten ist, und experimentell bestätigt scheint, die Thermospaltung des U^{235} dem 1/v -Gesetz folgt, ist es nötig, die Neutronen bis auf thermische Energien abzubremsen. Um ein möglichst schnelles Passieren der Gefahrenzone des Resonanzbandes zu bewirken, muß man die Masse der Bremssubstanz möglichst klein wählen, also eine wasserstoffhaltige Substanz zusetzen. Nun hat aber Wasserstoff auch einen Einfangquerschnitt für Einfangung von thermischen Neutronen, der der Reaktion $H^1, (n, \gamma) D^2$, entspricht. Man kann also von vornherein ohne jede Rechnung sagen, daß eine Kette nicht möglich ist, - selbst wenn das Resonanzgebiet passiert ist - wenn für thermische Neutronen

$$(\nu_{th} - 1)\, \sigma_{s,th}\, c_{235} < \sigma_{e,238}\, c_{238} + \sigma_{e,b}\, c_b \tag{13}$$

ist, wo ν_{th} wieder Zahl der beim Spaltprozess entstehenden Neutronen, $\sigma_{s,th}$ der Wirkungsquerschnitt des U^{235} für Spaltung $\sigma_{e,238}$ und $\sigma_{e,b}$ die Einfangquerschnitte für thermische Neutronen durch U^{238} bzw. die Bremssubstanz und die c, die entsprechenden Atomkonzentrationen bedeuten.

Zur genaueren Berechnung ist es erforderlich, die Wahrscheinlichkeit des Hauptprozesses, der Resonanzeinfangung zu berechnen. Bezeichnen wir mit w_r die Wahrscheinlichkeit eines Neutrons der Energie E, von U238 im Laufe seiner Abbremsung nicht resonanz-verschluckt zu werden, so gestaltet sich die Rechnung, die wir hier zunächst nur für leichten Wasserstoff als Bremssubstanz durchführen wollen sehr einfach. Für jeden einzelnen Stoß ist die Wahrscheinlichkeit einer Resonanzeinfangung u(E) gegeben durch

$$u(E) = \frac{\sigma_{c,238} \cdot c_{238}}{\sigma_{e,238} \cdot c_{238} + \sigma_{d,H} \cdot c_H} \tag{14}$$

Die Gesamtwahrscheinlichkeit w_r ergibt sich aus der Wahrscheinlichkeit u unter Berücksichtigung der Geschwindigkeitsverteilung, die aus (2) für isotrope Richtungsverteilung folgt. Für w_r gilt dann

$$E\, w_r(E) = \left[1 - u(E)\right] \int_0^E w_r(x)\, dx \tag{15}$$

und durch Differentiation die homogene Differentialgleichung

$$\frac{dw_r}{dE} - \left[\frac{u(E)}{E} + \frac{du}{dE} \cdot \frac{1}{1 - u(E)} \right] w_r = 0 \tag{16}$$

die durch den Ansatz

$$w_r = (1 - u) \cdot e^{-\int_0^E u(E) \cdot E^{-1} dE} \tag{17}$$

gelöst wird. Da wir E so groß wählen können, daß für E selbst $\sigma_{e,238}$ noch sehr klein ist, d.h. hinreichend hoch über der Resonanz, wird einfach

$$\ln w_r = - \int_0^\infty u \, d \ln E \tag{18}$$

Setzt man für den Verlauf von $\sigma_{e,238}$ die Breit-Wigner-Formel ein, so ist es günstig zunächst von dieser einen zu 1/v proportionalen Anteil des Wirkungsquerschnittes für

Energien, die hinreichend weit unter der Resonanzenergie liegen, abzuspalten. Die Ein-Niveauformel von Breit-Wigner für eine Resonanzeinfangung gibt:

$$\sigma_e = \sigma_o \cdot (E_\lambda / E)^{1/2} \cdot (\Gamma/2)^2 \left[(E - E_r)^2 + (\Gamma/2)^2 \right\}^{-1} \tag{19}$$

und dieses zerlegen wir in einen Anteil

$$\sigma' = \sigma_o \cdot (E_\lambda / E)^{1/2} \cdot (\Gamma/2)^2 \left[E_r^2 + (\Gamma/2)^2 \right]^{-1} \tag{20}$$

der erst bei thermischen Energien einen merklichen Beitrag zur Einfangung zeigt und den gleichen Gang mit 1/v aufweist, wie der Spaltungsquerschnitt, und einen eigentlichen Resonanzanteil

$$\sigma_{e,} = \sigma_o \cdot (E_\lambda / E)^{1/2} (\Gamma/2)^2 \left\{ \left[(E - E_\lambda)^2 + (\Gamma/2)^2 \right]^{-1} - \left[E^2 - (\Gamma/2)^2 \right]^{-1} \right\} \tag{21}$$

Dieser letzte Anteil läßt sich mit hinreichend guter Näherung für unsere Zwecke im Resonanzgebiet selbst, wo $u(E) \approx 1$ ist durch einen Ansatz der Form

$$\sigma_{e,r} \sim (E - E_r)^{-2} \tag{22}$$

darstellen und erhalten

$$\int_0^\infty u \, d(\ln E) = \beta \cdot \left(\frac{c_{238}}{c_H} \right)^{1/2} \tag{23}$$

wo β eine von der Linienbreite Γ abhängige Konstante ist. Somit wird, wenn wir

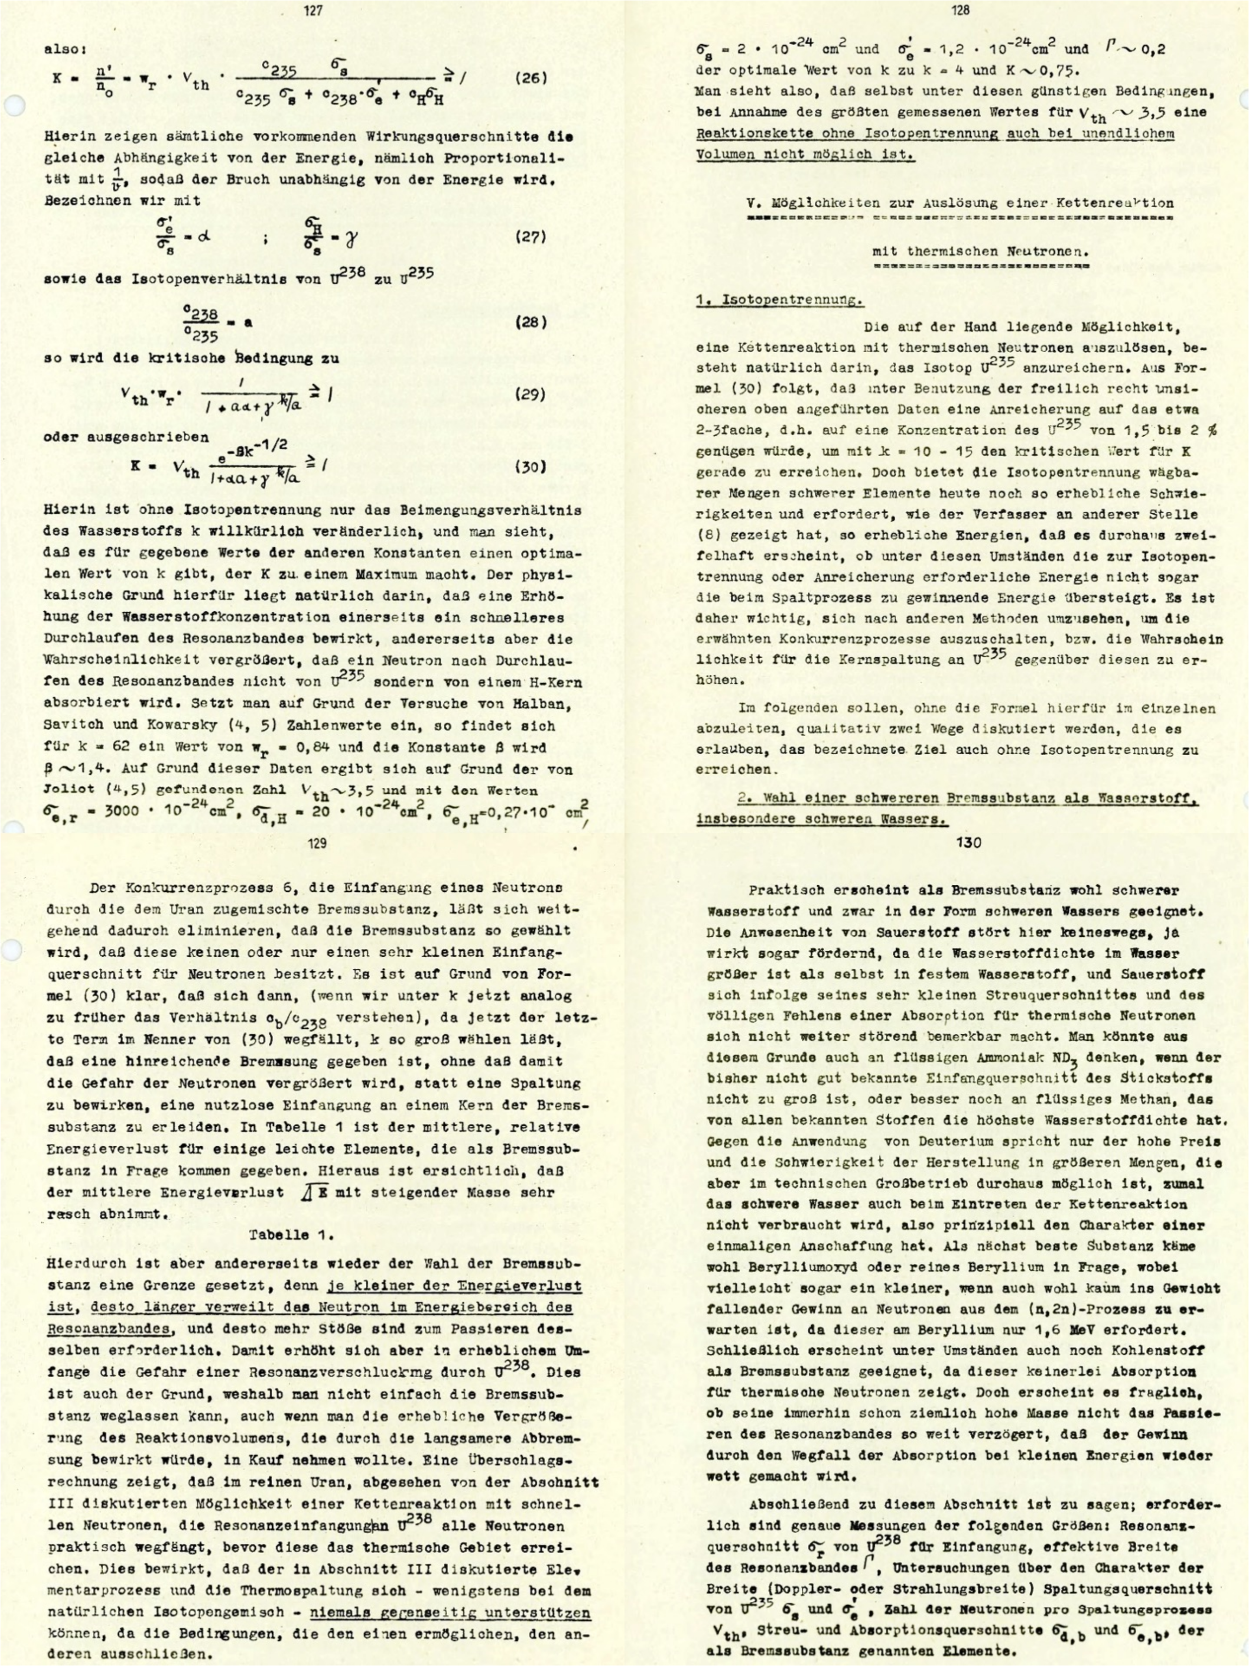
$$\frac{c_H}{c_{238}} = k \tag{24}$$

schreiben,

$$\ln w_r = - \beta\, k^{-1/2} \tag{25}$$

Wir können jetzt die Bedingung dafür, daß die Kettenreaktion nicht abreißt, formulieren: Die Zahl der Neutronen χ die durch ein Neutron erzeugt wird, muß größer als 1 sein,

Figure D.351: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].



also:

$$K = \frac{n'}{n_o} = w_r \cdot \nu_{th} \cdot \frac{c_{235}\,\sigma_s}{c_{235}\,\sigma_s + c_{238} \cdot \sigma'_e + c_H \sigma_H} \geqq 1 \qquad (26)$$

Hierin zeigen sämtliche vorkommenden Wirkungsquerschnitte die gleiche Abhängigkeit von der Energie, nämlich Proportionalität mit $\frac{1}{v}$, sodaß der Bruch unabhängig von der Energie wird. Bezeichnen wir mit

$$\frac{\sigma'_e}{\sigma_s} = \alpha \quad ; \quad \frac{\sigma_H}{\sigma_s} = \gamma \qquad (27)$$

sowie das Isotopenverhältnis von U^{238} zu U^{235}

$$\frac{c_{238}}{c_{235}} = a \qquad (28)$$

so wird die kritische Bedingung zu

$$\nu_{th} \cdot w_r \cdot \frac{1}{1 + a\alpha + \gamma\, k/a} \geqq 1 \qquad (29)$$

oder ausgeschrieben

$$K = \nu_{th} \frac{e^{-\beta k^{-1/2}}}{1 + \alpha a + \gamma\, k/a} \geqq 1 \qquad (30)$$

Hierin ist ohne Isotopentrennung nur das Beimengungsverhältnis des Wasserstoffs k willkürlich veränderlich, und man sieht, daß es für gegebene Werte der anderen Konstanten einen optimalen Wert von k gibt, der K zu einem Maximum macht. Der physikalische Grund hierfür liegt natürlich darin, daß eine Erhöhung der Wasserstoffkonzentration einerseits ein schnelleres Durchlaufen des Resonanzbandes bewirkt, andererseits aber die Wahrscheinlichkeit vergrößert, daß ein Neutron nach Durchlaufen des Resonanzbandes nicht von U^{235} sondern von einem H-Kern absorbiert wird. Setzt man auf Grund der Versuche von Halban, Savitch und Kowarsky (4, 5) Zahlenwerte ein, so findet sich für k = 62 ein Wert von $w_r = 0{,}84$ und die Konstante β wird $\beta \sim 1{,}4$. Auf Grund dieser Daten ergibt sich auf Grund der von Joliot (4,5) gefundenen Zahl $\nu_{th} \sim 3{,}5$ und mit den Werten $\sigma_{e,r} = 3000 \cdot 10^{-24}\,\mathrm{cm}^2$, $\sigma_{d,H} = 20 \cdot 10^{-24}\,\mathrm{cm}^2$, $\sigma_{e,H} = 0{,}27 \cdot 10^{-}\ \mathrm{cm}^2$,

$\sigma_s = 2 \cdot 10^{-24}\ \mathrm{cm}^2$ und $\sigma'_e = 1{,}2 \cdot 10^{-24}\mathrm{cm}^2$ und $\Gamma \sim 0{,}2$ der optimale Wert von k zu k = 4 und $K \sim 0{,}75$.
Man sieht also, daß selbst unter diesen günstigen Bedingungen, bei Annahme des größten gemessenen Wertes für $\nu_{th} \sim 3{,}5$ eine Reaktionskette ohne Isotopentrennung auch bei unendlichem Volumen nicht möglich ist.

V. Möglichkeiten zur Auslösung einer Kettenreaktion mit thermischen Neutronen.

1. Isotopentrennung.

Die auf der Hand liegende Möglichkeit, eine Kettenreaktion mit thermischen Neutronen auszulösen, besteht natürlich darin, das Isotop U^{235} anzureichern. Aus Formel (30) folgt, daß unter Benutzung der freilich recht unsicheren oben angeführten Daten eine Anreicherung auf das etwa 2-3fache, d.h. auf eine Konzentration des U^{235} von 1,5 bis 2 % genügen würde, um mit k = 10 - 15 den kritischen Wert für K gerade zu erreichen. Doch bietet die Isotopentrennung wägbarer Mengen schwerer Elemente heute noch so erhebliche Schwierigkeiten und erfordert, wie der Verfasser an anderer Stelle (8) gezeigt hat, so erhebliche Energien, daß es durchaus zweifelhaft erscheint, ob unter diesen Umständen die zur Isotopentrennung oder Anreicherung erforderliche Energie nicht sogar die beim Spaltprozess zu gewinnende Energie übersteigt. Es ist daher wichtig, sich nach anderen Methoden umzusehen, um die erwähnten Konkurrenzprozesse auszuschalten, bzw. die Wahrscheinlichkeit für die Kernspaltung an U^{235} gegenüber diesen zu erhöhen.

Im folgenden sollen, ohne die Formel hierfür im einzelnen abzuleiten, qualitativ zwei Wege diskutiert werden, die es erlauben, das bezeichnete Ziel auch ohne Isotopentrennung zu erreichen.

2. Wahl einer schwereren Bremssubstanz als Wasserstoff, insbesondere schweren Wassers.

Der Konkurrenzprozess 6, die Einfangung eines Neutrons durch die dem Uran zugemischte Bremssubstanz, läßt sich weitgehend dadurch eliminieren, daß die Bremssubstanz so gewählt wird, daß diese keinen oder nur einen sehr kleinen Einfangquerschnitt für Neutronen besitzt. Es ist auf Grund von Formel (30) klar, daß sich dann, (wenn wir unter k jetzt analog zu früher das Verhältnis c_b/c_{238} verstehen), da jetzt der letzte Term im Nenner von (30) wegfällt, k so groß wählen läßt, daß eine hinreichende Bremsung gegeben ist, ohne daß damit die Gefahr der Neutronen vergrößert wird, statt eine Spaltung zu bewirken, eine nutzlose Einfangung an einem Kern der Bremssubstanz zu erleiden. In Tabelle 1 ist der mittlere, relative Energieverlust für einige leichte Elemente, die als Bremssubstanz in Frage kommen gegeben. Hieraus ist ersichtlich, daß der mittlere Energieverlust ΔE mit steigender Masse sehr rasch abnimmt.

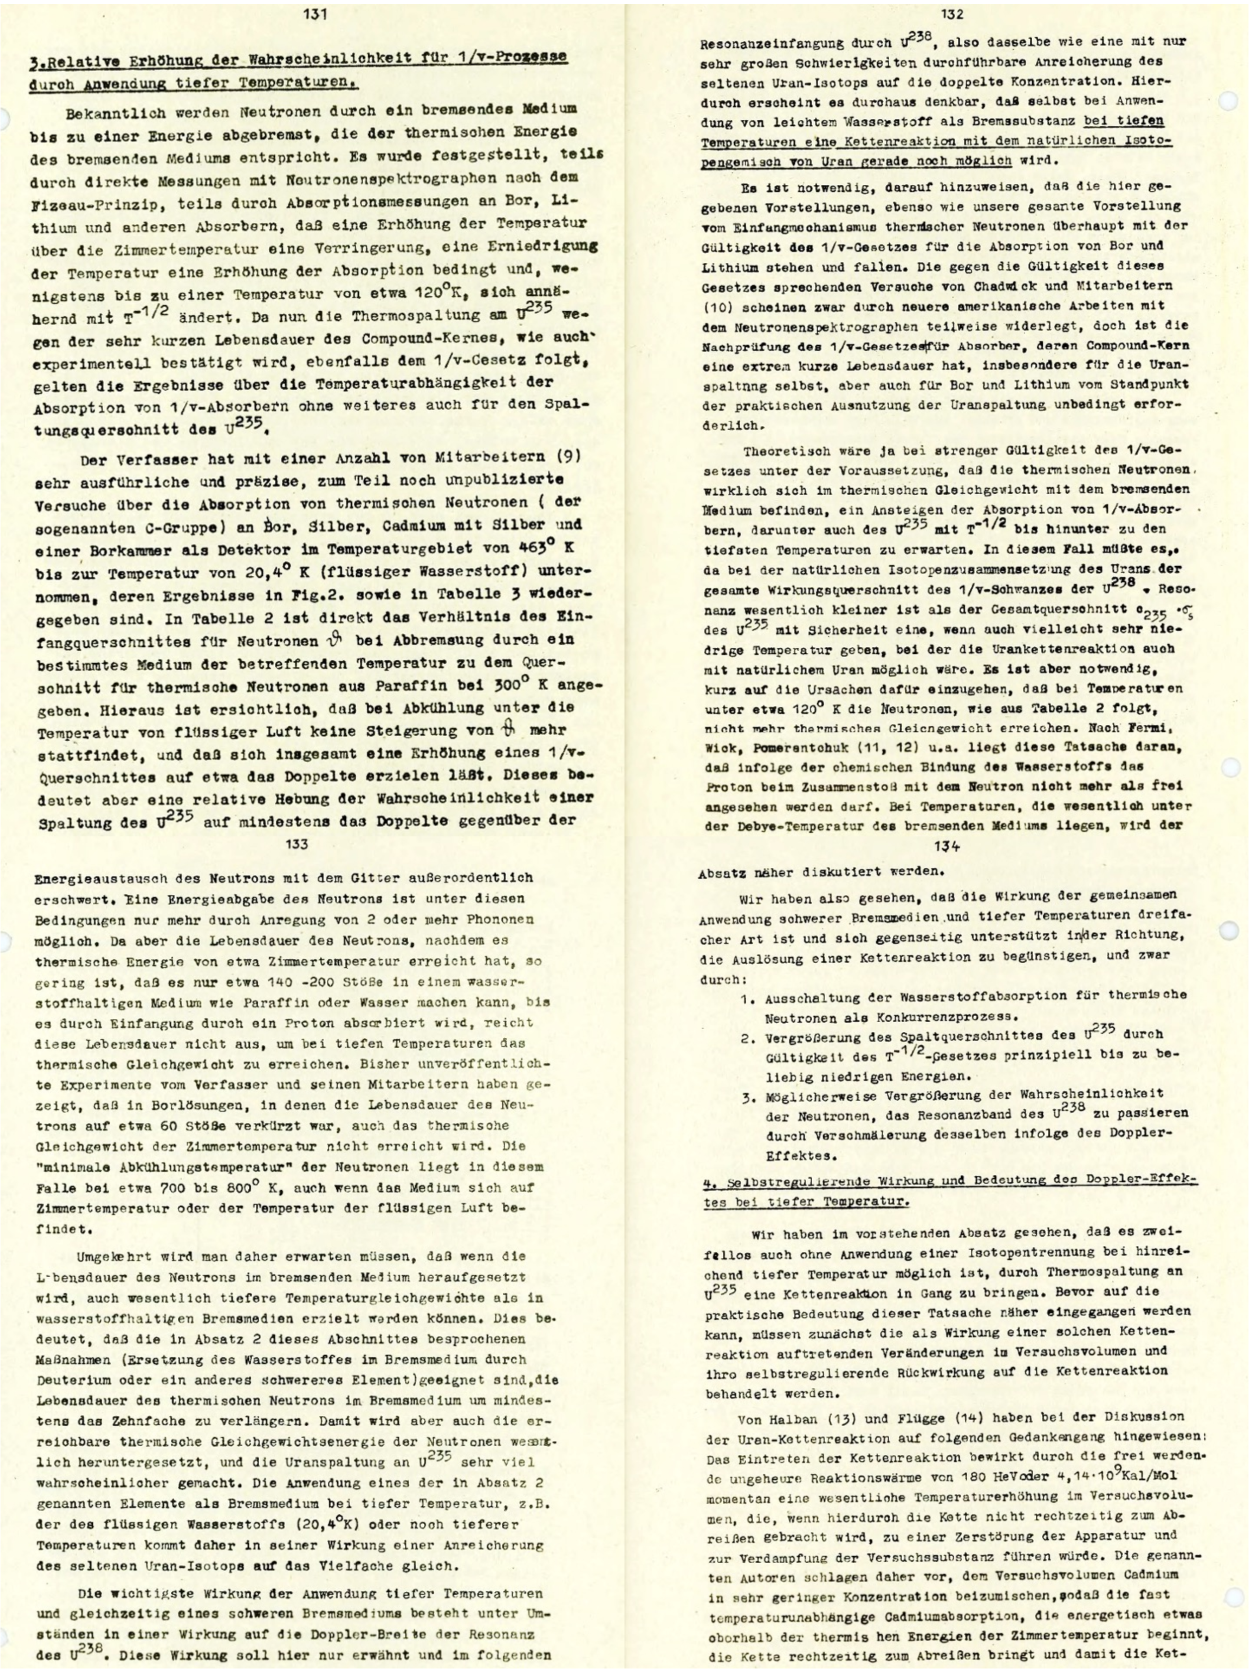
Tabelle 1.

Hierdurch ist aber andererseits wieder der Wahl der Bremssubstanz eine Grenze gesetzt, denn je kleiner der Energieverlust ist, desto länger verweilt das Neutron im Energiebereich des Resonanzbandes, und desto mehr Stöße sind zum Passieren desselben erforderlich. Damit erhöht sich aber in erheblichem Umfange die Gefahr einer Resonanzverschluckung durch U^{238}. Dies ist auch der Grund, weshalb man nicht einfach die Bremssubstanz weglassen kann, auch wenn man die erhebliche Vergrößerung des Reaktionsvolumens, die durch die langsamere Abbremsung bewirkt würde, in Kauf nehmen wollte. Eine Überschlagsrechnung zeigt, daß im reinen Uran, abgesehen von der Abschnitt III diskutierten Möglichkeit einer Kettenreaktion mit schnellen Neutronen, die Resonanzeinfangung an U^{238} alle Neutronen praktisch wegfängt, bevor diese das thermische Gebiet erreichen. Dies bewirkt, daß der in Abschnitt III diskutierte Elementarprozess und die Thermospaltung sich - wenigstens bei dem natürlichen Isotopengemisch - niemals gegenseitig unterstützen können, da die Bedingungen, die den einen ermöglichen, den anderen ausschließen.

Praktisch erscheint als Bremssubstanz wohl schwerer Wasserstoff und zwar in der Form schweren Wassers geeignet. Die Anwesenheit von Sauerstoff stört hier keineswegs, ja wirkt sogar fördernd, da die Wasserstoffdichte im Wasser größer ist als selbst in festem Wasserstoff, und Sauerstoff sich infolge seines sehr kleinen Streuquerschnittes und des völligen Fehlens einer Absorption für thermische Neutronen sich nicht weiter störend bemerkbar macht. Man könnte aus diesem Grunde auch an flüssigen Ammoniak ND_3 denken, wenn der bisher nicht gut bekannte Einfangquerschnitt des Stickstoffs nicht zu groß ist, oder besser noch an flüssiges Methan, das von allen bekannten Stoffen die höchste Wasserstoffdichte hat. Gegen die Anwendung von Deuterium spricht nur der hohe Preis und die Schwierigkeit der Herstellung in größeren Mengen, die aber im technischen Großbetrieb durchaus möglich ist, zumal das schwere Wasser auch beim Eintreten der Kettenreaktion nicht verbraucht wird, also prinzipiell den Charakter einer einmaligen Anschaffung hat. Als nächst beste Substanz käme wohl Berylliumoxyd oder reines Beryllium in Frage, wobei vielleicht sogar ein kleiner, wenn auch wohl kaum ins Gewicht fallender Gewinn an Neutronen aus dem (n,2n)-Prozess zu erwarten ist, da dieser am Beryllium nur 1,6 MeV erfordert. Schließlich erscheint unter Umständen auch noch Kohlenstoff als Bremssubstanz geeignet, da dieser keinerlei Absorption für thermische Neutronen zeigt. Doch erscheint es fraglich, ob seine immerhin schon ziemlich hohe Masse nicht das Passieren des Resonanzbandes so weit verzögert, daß der Gewinn durch den Wegfall der Absorption bei kleinen Energien wieder wett gemacht wird.

Abschließend zu diesem Abschnitt ist zu sagen; erforderlich sind genaue Messungen der folgenden Größen: Resonanzquerschnitt σ_r von U^{238} für Einfangung, effektive Breite des Resonanzbandes Γ, Untersuchungen über den Charakter der Breite (Doppler- oder Strahlungsbreite) Spaltungsquerschnitt von U^{235} σ_s und σ'_e, Zahl der Neutronen pro Spaltungsprozess ν_{th}, Streu- und Absorptionsquerschnitte $\sigma_{d,b}$ und $\sigma_{e,b}$, der als Bremssubstanz genannten Elemente.

Figure D.352: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].



3.Relative Erhöhung der Wahrscheinlichkeit für 1/v-Prozesse durch Anwendung tiefer Temperaturen.

Bekanntlich werden Neutronen durch ein bremsendes Medium bis zu einer Energie abgebremst, die der thermischen Energie des bremsenden Mediums entspricht. Es wurde festgestellt, teils durch direkte Messungen mit Neutronenspektrographen nach dem Fizeau-Prinzip, teils durch Absorptionsmessungen an Bor, Lithium und anderen Absorbern, daß eine Erhöhung der Temperatur über die Zimmertemperatur eine Verringerung, eine Erniedrigung der Temperatur eine Erhöhung der Absorption bedingt und, wenigstens bis zu einer Temperatur von etwa 120°K, sich annähernd mit $T^{-1/2}$ ändert. Da nun die Thermospaltung am U^{235} wegen der sehr kurzen Lebensdauer des Compound-Kernes, wie auch experimentell bestätigt wird, ebenfalls dem 1/v-Gesetz folgt, gelten die Ergebnisse über die Temperaturabhängigkeit der Absorption von 1/v-Absorbern ohne weiteres auch für den Spaltungsquerschnitt des U^{235}.

Der Verfasser hat mit einer Anzahl von Mitarbeitern (9) sehr ausführliche und präzise, zum Teil noch unpublizierte Versuche über die Absorption von thermischen Neutronen (der sogenannten C-Gruppe) an Bor, Silber, Cadmium mit Silber und einer Borkammer als Detektor im Temperaturgebiet von 463° K bis zur Temperatur von 20,4° K (flüssiger Wasserstoff) unternommen, deren Ergebnisse in Fig.2. sowie in Tabelle 3 wiedergegeben sind. In Tabelle 2 ist direkt das Verhältnis des Einfangquerschnittes für Neutronen ϑ bei Abbremsung durch ein bestimmtes Medium der betreffenden Temperatur zu dem Querschnitt für thermische Neutronen aus Paraffin bei 300° K angegeben. Hieraus ist ersichtlich, daß bei Abkühlung unter die Temperatur von flüssiger Luft keine Steigerung von ϑ mehr stattfindet, und daß sich insgesamt eine Erhöhung eines 1/v-Querschnittes auf etwa das Doppelte erzielen läßt. Dieses bedeutet aber eine relative Hebung der Wahrscheinlichkeit einer Spaltung des U^{235} auf mindestens das Doppelte gegenüber der Resonanzeinfangung durch U^{238}, also dasselbe wie eine mit nur sehr großen Schwierigkeiten durchführbare Anreicherung des seltenen Uran-Isotops auf die doppelte Konzentration. Hierdurch erscheint es durchaus denkbar, daß selbst bei Anwendung von leichtem Wasserstoff als Bremssubstanz bei tiefen Temperaturen eine Kettenreaktion mit dem natürlichen Isotopengemisch von Uran gerade noch möglich wird.

Es ist notwendig, darauf hinzuweisen, daß die hier gegebenen Vorstellungen, ebenso wie unsere gesamte Vorstellung vom Einfangmechanismus thermischer Neutronen überhaupt mit der Gültigkeit des 1/v-Gesetzes für die Absorption von Bor und Lithium stehen und fallen. Die gegen die Gültigkeit dieses Gesetzes sprechenden Versuche von Chadwick und Mitarbeitern (10) scheinen zwar durch neuere amerikanische Arbeiten mit dem Neutronenspektrographen teilweise widerlegt, doch ist die Nachprüfung des 1/v-Gesetzes für Absorber, deren Compound-Kern eine extrem kurze Lebensdauer hat, insbesondere für die Uranspaltung selbst, aber auch für Bor und Lithium vom Standpunkt der praktischen Ausnutzung der Uranspaltung unbedingt erforderlich.

Theoretisch wäre ja bei strenger Gültigkeit des 1/v-Gesetzes unter der Voraussetzung, daß die thermischen Neutronen wirklich sich im thermischen Gleichgewicht mit dem bremsenden Medium befinden, ein Ansteigen der Absorption von 1/v-Absorbern, darunter auch des U^{235} mit $T^{-1/2}$ bis hinunter zu den tiefsten Temperaturen zu erwarten. In diesem Fall müßte es, da bei der natürlichen Isotopenzusammensetzung des Urans der gesamte Wirkungsquerschnitt des 1/v-Schwanzes der U^{238} - Resonanz wesentlich kleiner ist als der Gesamtquerschnitt $\sigma_{235} \cdot \sigma_s$ des U^{235} mit Sicherheit eine, wenn auch vielleicht sehr niedrige Temperatur geben, bei der die Urankettenreaktion auch mit natürlichem Uran möglich wäre. Es ist aber notwendig, kurz auf die Ursachen dafür einzugehen, daß bei Temperaturen unter etwa 120° K die Neutronen, wie aus Tabelle 2 folgt, nicht mehr thermisches Gleichgewicht erreichen. Nach Fermi, Wick, Pomerantchuk (11, 12) u.a. liegt diese Tatsache daran, daß infolge der chemischen Bindung des Wasserstoffs das Proton beim Zusammenstoß mit dem Neutron nicht mehr als frei angesehen werden darf. Bei Temperaturen, die wesentlich unter der Debye-Temperatur des bremsenden Mediums liegen, wird der Energieaustausch des Neutrons mit dem Gitter außerordentlich erschwert. Eine Energieabgabe des Neutrons ist unter diesen Bedingungen nur mehr durch Anregung von 2 oder mehr Phononen möglich. Da aber die Lebensdauer des Neutrons, nachdem es thermische Energie von etwa Zimmertemperatur erreicht hat, so gering ist, daß es nur etwa 140 -200 Stöße in einem wasserstoffhaltigen Medium wie Paraffin oder Wasser machen kann, bis es durch Einfangung durch ein Proton absorbiert wird, reicht diese Lebensdauer nicht aus, um bei tiefen Temperaturen das thermische Gleichgewicht zu erreichen. Bisher unveröffentlichte Experimente vom Verfasser und seinen Mitarbeitern haben gezeigt, daß in Borlösungen, in denen die Lebensdauer des Neutrons auf etwa 60 Stöße verkürzt war, auch das thermische Gleichgewicht der Zimmertemperatur nicht erreicht wird. Die "minimale Abkühlungstemperatur" der Neutronen liegt in diesem Falle bei etwa 700 bis 800° K, auch wenn das Medium sich auf Zimmertemperatur oder der Temperatur der flüssigen Luft befindet.

Umgekehrt wird man daher erwarten müssen, daß wenn die Lebensdauer des Neutrons im bremsenden Medium heraufgesetzt wird, auch wesentlich tiefere Temperaturgleichgewichte als in wasserstoffhaltigen Bremsmedien erzielt werden können. Dies bedeutet, daß die in Absatz 2 dieses Abschnittes besprochenen Maßnahmen (Ersetzung des Wasserstoffes im Bremsmedium durch Deuterium oder ein anderes schwereres Element)geeignet sind,die Lebensdauer des thermischen Neutrons im Bremsmedium um mindestens das Zehnfache zu verlängern. Damit wird aber auch die erreichbare thermische Gleichgewichtsenergie der Neutronen wesentlich heruntergesetzt, und die Uranspaltung an U^{235} sehr viel wahrscheinlicher gemacht. Die Anwendung eines der in Absatz 2 genannten Elemente als Bremsmedium bei tiefer Temperatur, z.B. der des flüssigen Wasserstoffs (20,4°K) oder noch tieferer Temperaturen kommt daher in seiner Wirkung einer Anreicherung des seltenen Uran-Isotops auf das Vielfache gleich.

Die wichtigste Wirkung der Anwendung tiefer Temperaturen und gleichzeitig eines schweren Bremsmediums besteht unter Umständen in einer Wirkung auf die Doppler-Breite der Resonanz des U^{238}. Diese Wirkung soll hier nur erwähnt und im folgenden Absatz näher diskutiert werden.

Wir haben also gesehen, daß die Wirkung der gemeinsamen Anwendung schwerer Bremsmedien und tiefer Temperaturen dreifacher Art ist und sich gegenseitig unterstützt in der Richtung, die Auslösung einer Kettenreaktion zu begünstigen, und zwar durch:

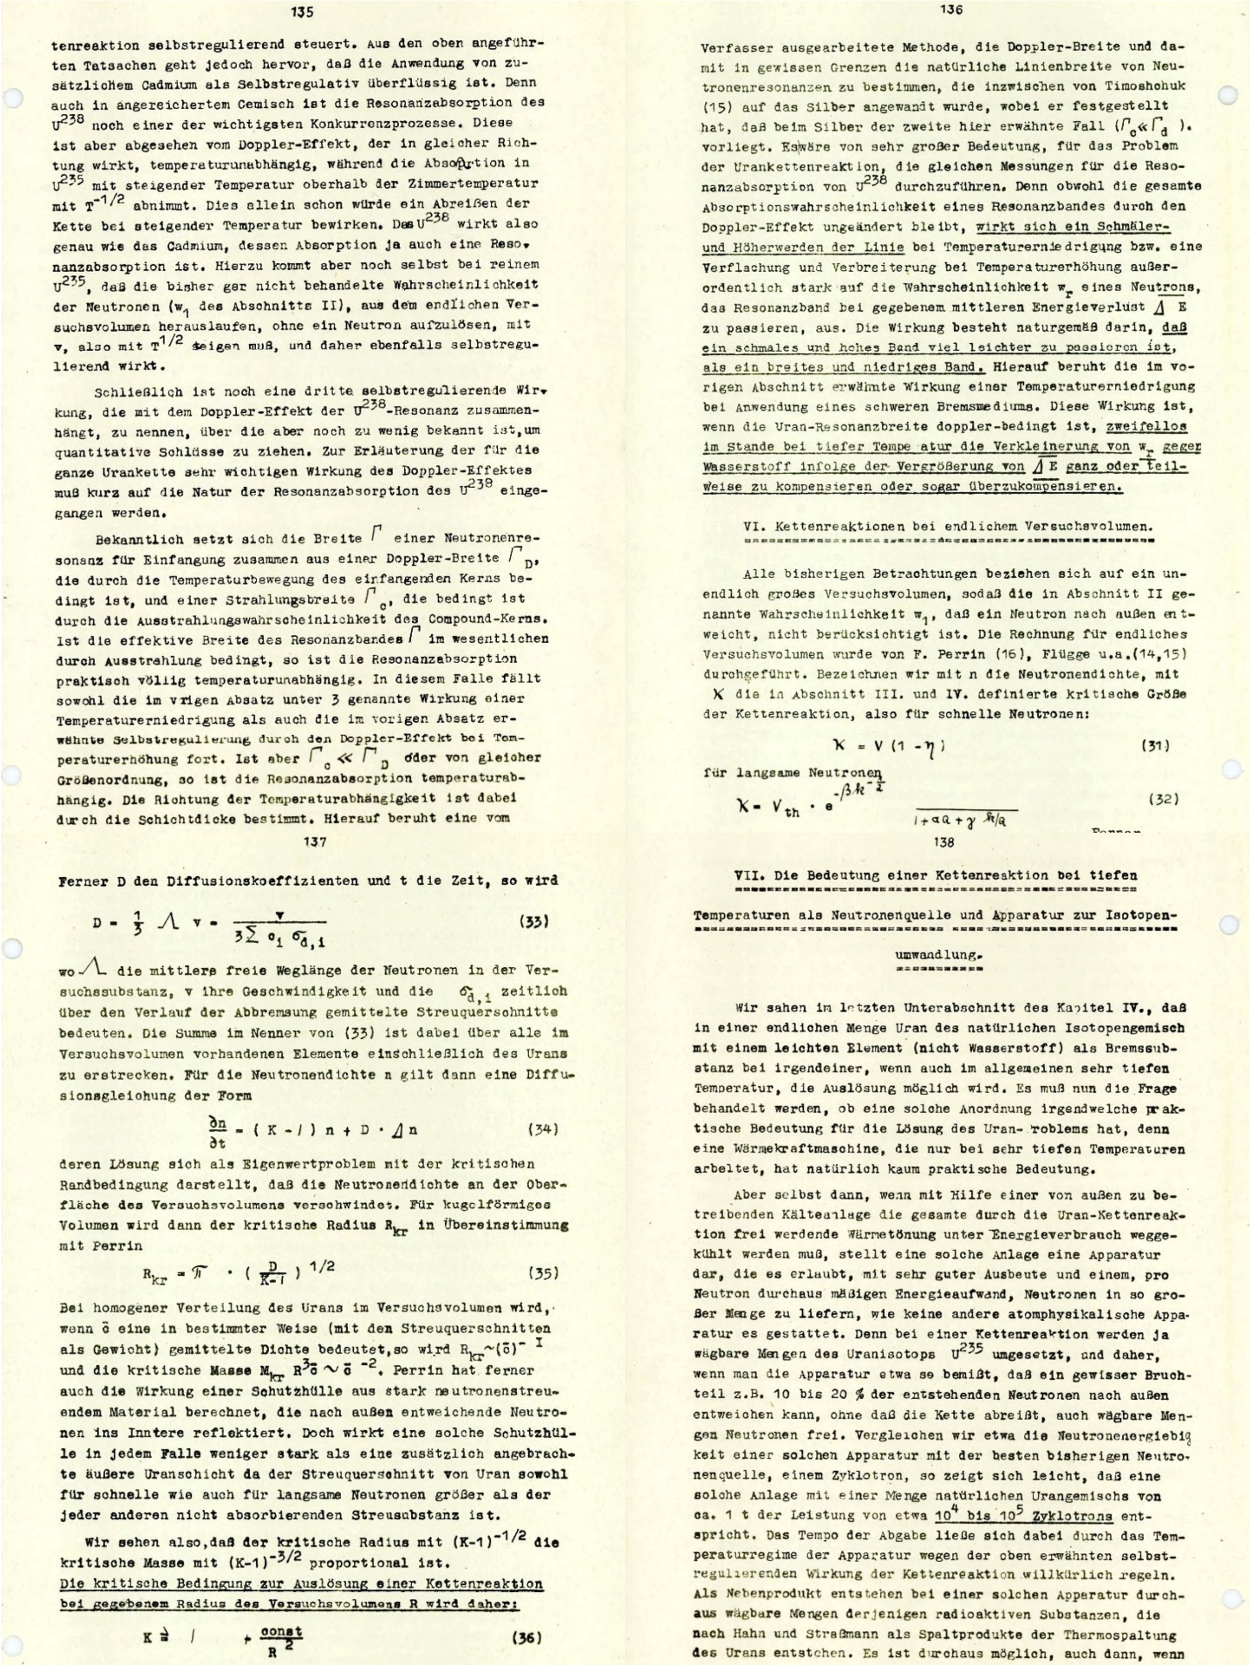
1. Ausschaltung der Wasserstoffabsorption für thermische Neutronen als Konkurrenzprozess.
2. Vergrößerung des Spaltquerschnittes des U^{235} durch Gültigkeit des $T^{-1/2}$-Gesetzes prinzipiell bis zu beliebig niedrigen Energien.
3. Möglicherweise Vergrößerung der Wahrscheinlichkeit der Neutronen, das Resonanzband des U^{238} zu passieren durch Verschmälerung desselben infolge des Doppler-Effektes.

4. Selbstregulierende Wirkung und Bedeutung des Doppler-Effektes bei tiefer Temperatur.

Wir haben im vorstehenden Absatz gesehen, daß es zweifellos auch ohne Anwendung einer Isotopentrennung bei hinreichend tiefer Temperatur möglich ist, durch Thermospaltung an U^{235} eine Kettenreaktion in Gang zu bringen. Bevor auf die praktische Bedeutung dieser Tatsache näher eingegangen werden kann, müssen zunächst die als Wirkung einer solchen Kettenreaktion auftretenden Veränderungen im Versuchsvolumen und ihre selbstregulierende Rückwirkung auf die Kettenreaktion behandelt werden.

Von Halban (13) und Flügge (14) haben bei der Diskussion der Uran-Kettenreaktion auf folgenden Gedankengang hingewiesen: Das Eintreten der Kettenreaktion bewirkt durch die frei werdende ungeheure Reaktionswärme von 180 MeV oder $4,14 \cdot 10^9$ Kal/Mol momentan eine wesentliche Temperaturerhöhung im Versuchsvolumen, die, wenn hierdurch die Kette nicht rechtzeitig zum Abreißen gebracht wird, zu einer Zerstörung der Apparatur und zur Verdampfung der Versuchssubstanz führen würde. Die genannten Autoren schlagen daher vor, dem Versuchsvolumen Cadmium in sehr geringer Konzentration beizumischen,sodaß die fast temperaturunabhängige Cadmiumabsorption, die energetisch etwas oberhalb der thermischen Energien der Zimmertemperatur beginnt, die Kette rechtzeitig zum Abreißen bringt und damit die Ket-

Figure D.353: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].



tenreaktion selbstregulierend steuert. Aus den oben angeführten Tatsachen geht jedoch hervor, daß die Anwendung von zusätzlichem Cadmium als Selbstregulativ überflüssig ist. Denn auch in angereichertem Cemisch ist die Resonanzabsorption des U^{238} noch einer der wichtigsten Konkurrenzprozesse. Diese ist aber abgesehen vom Doppler-Effekt, der in gleicher Richtung wirkt, temperaturunabhängig, während die Absorption in U^{235} mit steigender Temperatur oberhalb der Zimmertemperatur mit $T^{-1/2}$ abnimmt. Dies allein schon würde ein Abreißen der Kette bei steigender Temperatur bewirken. Das U^{238} wirkt also genau wie das Cadmium, dessen Absorption ja auch eine Resonanzabsorption ist. Hierzu kommt aber noch selbst bei reinem U^{235}, daß die bisher gar nicht behandelte Wahrscheinlichkeit der Neutronen (w_1 des Abschnitts II), aus dem endlichen Versuchsvolumen herauslaufen, ohne ein Neutron aufzulösen, mit v, also mit $T^{1/2}$ steigen muß, und daher ebenfalls selbstregulierend wirkt.

Schließlich ist noch eine dritte selbstregulierende Wirkung, die mit dem Doppler-Effekt der U^{238}-Resonanz zusammenhängt, zu nennen, über die aber noch zu wenig bekannt ist, um quantitative Schlüsse zu ziehen. Zur Erläuterung der für die ganze Urankette sehr wichtigen Wirkung des Doppler-Effektes muß kurz auf die Natur der Resonanzabsorption des U^{238} eingegangen werden.

Bekanntlich setzt sich die Breite Γ einer Neutronenresonanz für Einfangung zusammen aus einer Doppler-Breite Γ_D, die durch die Temperaturbewegung des einfangenden Kerns bedingt ist, und einer Strahlungsbreite Γ_c, die bedingt ist durch die Ausstrahlungswahrscheinlichkeit des Compound-Kerns. Ist die effektive Breite des Resonanzbandes Γ im wesentlichen durch Ausstrahlung bedingt, so ist die Resonanzabsorption praktisch völlig temperaturunabhängig. In diesem Falle fällt sowohl die im vorigen Absatz unter 3 genannte Wirkung einer Temperaturerniedrigung als auch die im vorigen Absatz erwähnte Selbstregulierung durch den Doppler-Effekt bei Temperaturerhöhung fort. Ist aber $\Gamma_c \ll \Gamma_D$ oder von gleicher Größenordnung, so ist die Resonanzabsorption temperaturabhängig. Die Richtung der Temperaturabhängigkeit ist dabei durch die Schichtdicke bestimmt. Hierauf beruht eine vom

Verfasser ausgearbeitete Methode, die Doppler-Breite und damit in gewissen Grenzen die natürliche Linienbreite von Neutronenresonanzen zu bestimmen, die inzwischen von Timoshchuk (15) auf das Silber angewandt wurde, wobei er festgestellt hat, daß beim Silber der zweite hier erwähnte Fall ($\Gamma_c \ll \Gamma_d$). vorliegt. Es wäre von sehr großer Bedeutung, für das Problem der Urankettenreaktion, die gleichen Messungen für die Resonanzabsorption von U^{238} durchzuführen. Denn obwohl die gesamte Absorptionswahrscheinlichkeit eines Resonanzbandes durch den Doppler-Effekt ungeändert bleibt, wirkt sich ein Schmäler- und Höherwerden der Linie bei Temperaturerniedrigung bzw. eine Verflachung und Verbreiterung bei Temperaturerhöhung außerordentlich stark auf die Wahrscheinlichkeit w_r eines Neutrons, das Resonanzband bei gegebenem mittleren Energieverlust ΔE zu passieren, aus. Die Wirkung besteht naturgemäß darin, daß ein schmales und hohes Band viel leichter zu passieren ist, als ein breites und niedriges Band. Hierauf beruht die im vorigen Abschnitt erwähnte Wirkung einer Temperaturerniedrigung bei Anwendung eines schweren Bremsmediums. Diese Wirkung ist, wenn die Uran-Resonanzbreite doppler-bedingt ist, zweifellos im Stande bei tiefer Temperatur die Verkleinerung von w_r gegen Wasserstoff infolge der Vergrößerung von ΔE ganz oder teilweise zu kompensieren oder sogar überzukompensieren.

VI. Kettenreaktionen bei endlichem Versuchsvolumen.

Alle bisherigen Betrachtungen beziehen sich auf ein unendlich großes Versuchsvolumen, sodaß die in Abschnitt II genannte Wahrscheinlichkeit w_1, daß ein Neutron nach außen entweicht, nicht berücksichtigt ist. Die Rechnung für endliches Versuchsvolumen wurde von F. Perrin (16), Flügge u.a.(14,15) durchgeführt. Bezeichnen wir mit n die Neutronendichte, mit κ die in Abschnitt III. und IV. definierte kritische Größe der Kettenreaktion, also für schnelle Neutronen:

$$\kappa = \nu\,(1-\eta) \qquad (31)$$

für langsame Neutronen

$$\kappa = \nu_{th} \cdot e^{-\beta k^{-\frac{1}{2}}} \qquad \frac{\qquad}{1+aQ+\gamma\, k/Q} \qquad (32)$$

Ferner D den Diffusionskoeffizienten und t die Zeit, so wird

$$D = \frac{1}{3}\,\Lambda\, v = \frac{v}{3\sum c_i\,\sigma_{d,i}} \qquad (33)$$

wo Λ die mittlere freie Weglänge der Neutronen in der Versuchssubstanz, v ihre Geschwindigkeit und die $\sigma_{d,i}$ zeitlich über den Verlauf der Abbremsung gemittelte Streuquerschnitte bedeuten. Die Summe im Nenner von (33) ist dabei über alle im Versuchsvolumen vorhandenen Elemente einschließlich des Urans zu erstrecken. Für die Neutronendichte n gilt dann eine Diffusionsgleichung der Form

$$\frac{\partial n}{\partial t} = (K-1)\,n + D \cdot \Delta n \qquad (34)$$

deren Lösung sich als Eigenwertproblem mit der kritischen Randbedingung darstellt, daß die Neutronendichte an der Oberfläche des Versuchsvolumens verschwindet. Für kugelförmiges Volumen wird dann der kritische Radius R_{kr} in Übereinstimmung mit Perrin

$$R_{kr} = \pi \cdot \left(\frac{D}{K-1}\right)^{1/2} \qquad (35)$$

Bei homogener Verteilung des Urans im Versuchsvolumen wird, wenn $\bar{c}$ eine in bestimmter Weise (mit den Streuquerschnitten als Gewicht) gemittelte Dichte bedeutet, so wird $R_{kr} \sim (\bar{c})^{-1}$ und die kritische Masse $M_{kr}\ R^3\bar{c} \sim \bar{c}^{-2}$. Perrin hat ferner auch die Wirkung einer Schutzhülle aus stark neutronenstreuendem Material berechnet, die nach außen entweichende Neutronen ins Inntere reflektiert. Doch wirkt eine solche Schutzhülle in jedem Falle weniger stark als eine zusätzlich angebrachte äußere Uranschicht da der Streuquerschnitt von Uran sowohl für schnelle wie auch für langsame Neutronen größer als der jeder anderen nicht absorbierenden Streusubstanz ist.

Wir sehen also, daß der kritische Radius mit $(K-1)^{-1/2}$ die kritische Masse mit $(K-1)^{-3/2}$ proportional ist. Die kritische Bedingung zur Auslösung einer Kettenreaktion bei gegebenem Radius des Versuchsvolumens R wird daher:

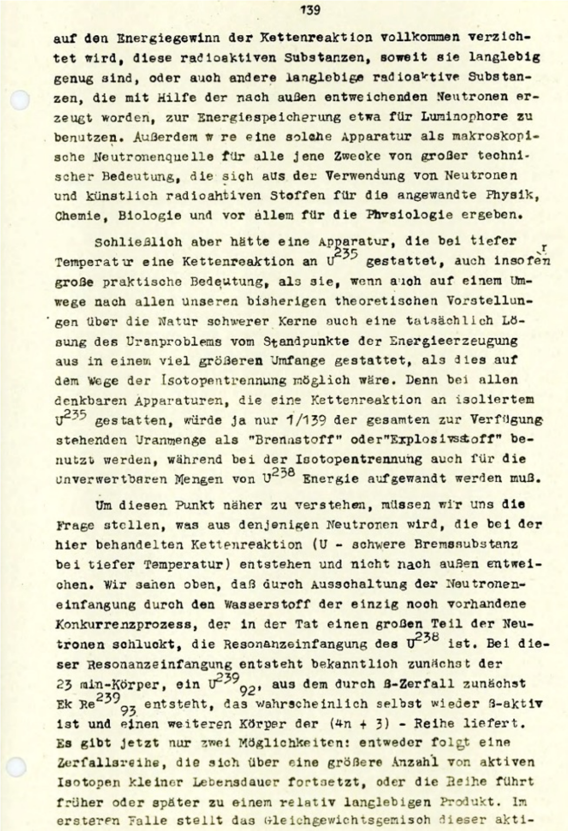
$$K \geqq 1 + \frac{\text{const}}{R^2} \qquad (36)$$

VII. Die Bedeutung einer Kettenreaktion bei tiefen Temperaturen als Neutronenquelle und Apparatur zur Isotopenumwandlung.

Wir sahen im letzten Unterabschnitt des Kapitel IV., daß in einer endlichen Menge Uran des natürlichen Isotopengemisch mit einem leichten Element (nicht Wasserstoff) als Bremssubstanz bei irgendeiner, wenn auch im allgemeinen sehr tiefen Temperatur, die Auslösung möglich wird. Es muß nun die Frage behandelt werden, ob eine solche Anordnung irgendwelche praktische Bedeutung für die Lösung des Uran-Problems hat, denn eine Wärmekraftmaschine, die nur bei sehr tiefen Temperaturen arbeitet, hat natürlich kaum praktische Bedeutung.

Aber selbst dann, wenn mit Hilfe einer von außen zu betreibenden Kälteanlage die gesamte durch die Uran-Kettenreaktion frei werdende Wärmetönung unter Energieverbrauch weggekühlt werden muß, stellt eine solche Anlage eine Apparatur dar, die es erlaubt, mit sehr guter Ausbeute und einem, pro Neutron durchaus mäßigen Energieaufwand, Neutronen in so großer Menge zu liefern, wie keine andere atomphysikalische Apparatur es gestattet. Denn bei einer Kettenreaktion werden ja wägbare Mengen des Uranisotops U^{235} umgesetzt, und daher, wenn man die Apparatur etwa so bemißt, daß ein gewisser Bruchteil z.B. 10 bis 20 % der entstehenden Neutronen nach außen entweichen kann, ohne daß die Kette abreißt, auch wägbare Mengen Neutronen frei. Vergleichen wir etwa die Neutronenergiebigkeit einer solchen Apparatur mit der besten bisherigen Neutronenquelle, einem Zyklotron, so zeigt sich leicht, daß eine solche Anlage mit einer Menge natürlichen Urangemischs von ca. 1 t der Leistung von etwa 10^4 bis 10^5 Zyklotrons entspricht. Das Tempo der Abgabe ließe sich dabei durch das Temperaturregime der Apparatur wegen der oben erwähnten selbstregulierenden Wirkung der Kettenreaktion willkürlich regeln. Als Nebenprodukt entstehen bei einer solchen Apparatur durchaus wägbare Mengen derjenigen radioaktiven Substanzen, die nach Hahn und Straßmann als Spaltprodukte der Thermospaltung des Urans entstehen. Es ist durchaus möglich, auch dann, wenn

Figure D.354: The August 1941 report by Fritz Houtermans (working in collaboration with Manfred von Ardenne) explaining the feasibility of breeding plutonium-239 and using it to make fission bombs. [G-94].

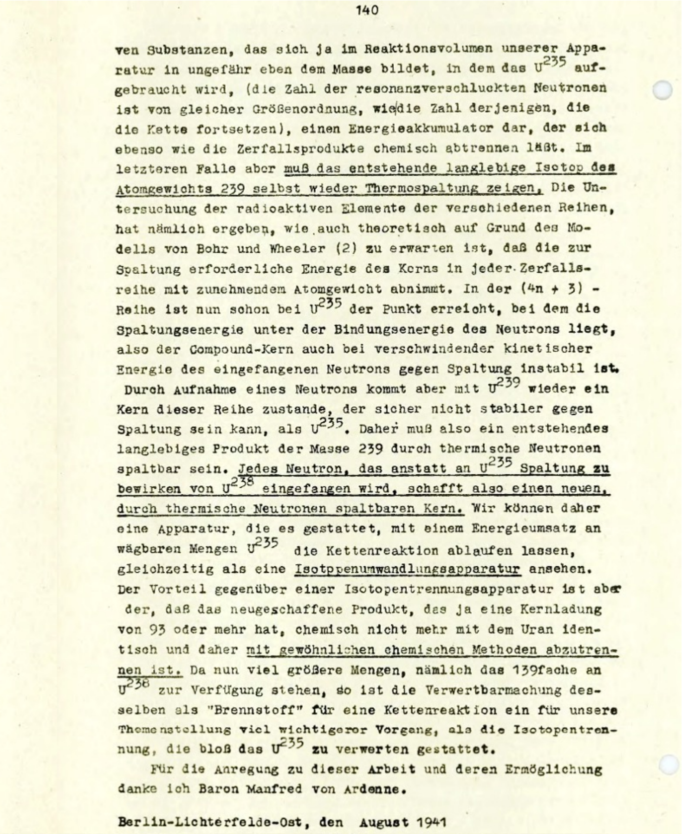


139

auf den Energiegewinn der Kettenreaktion vollkommen verzichtet wird, diese radioaktiven Substanzen, soweit sie langlebig genug sind, oder auch andere langlebige radioaktive Substanzen, die mit Hilfe der nach außen entweichenden Neutronen erzeugt worden, zur Energiespeicherung etwa für Luminophore zu benutzen. Außerdem w re eine solche Apparatur als makroskopische Neutronenquelle für alle jene Zwecke von großer technischer Bedeutung, die sich aus der Verwendung von Neutronen und künstlich radioahtiven Stoffen für die angewandte Physik, Chemie, Biologie und vor allem für die Phvsiologie ergeben.

Schließlich aber hätte eine Apparatur, die bei tiefer Temperatur eine Kettenreaktion an U^{235} gestattet, auch insofern große praktische Bedeutung, als sie, wenn auch auf einem Umwege nach allen unseren bisherigen theoretischen Vorstellungen über die Natur schwerer Kerne auch eine tatsächlich Lösung des Uranproblems vom Standpunkte der Energieerzeugung aus in einem viel größeren Umfange gestattet, als dies auf dem Wege der Isotopentrennung möglich wäre. Denn bei allen denkbaren Apparaturen, die eine Kettenreaktion an isoliertem U^{235} gestatten, würde ja nur 1/139 der gesamten zur Verfügung stehenden Uranmenge als "Brennstoff" oder"Explosivstoff" benutzt werden, während bei der Isotopentrennung auch für die unverwertbaren Mengen von U^{238} Energie aufgewandt werden muß.

Um diesen Punkt näher zu verstehen, müssen wir uns die Frage stellen, was aus denjenigen Neutronen wird, die bei der hier behandelten Kettenreaktion (U - schwere Bremssubstanz bei tiefer Temperatur) entstehen und nicht nach außen entweichen. Wir sahen oben, daß durch Ausschaltung der Neutroneneinfangung durch den Wasserstoff der einzig noch vorhandene Konkurrenzprozess, der in der Tat einen großen Teil der Neutronen schluckt, die Resonanzeinfangung des U^{238} ist. Bei dieser Resonanzeinfangung entsteht bekanntlich zunächst der 23 min-Körper, ein $U^{239}{}_{92}$, aus dem durch ß-Zerfall zunächst Ek $Re^{239}{}_{93}$ entsteht, das wahrscheinlich selbst wieder ß-aktiv ist und einen weiteren Körper der (4n + 3) - Reihe liefert. Es gibt jetzt nur zwei Möglichkeiten: entweder folgt eine Zerfallsreihe, die sich über eine größere Anzahl von aktiven Isotopen kleiner Lebensdauer fortsetzt, oder die Reihe führt früher oder später zu einem relativ langlebigen Produkt. Im ersteren Falle stellt das Gleichgewichtsgemisch dieser akti-



140

ven Substanzen, das sich ja im Reaktionsvolumen unserer Apparatur in ungefähr eben dem Masse bildet, in dem das U^{235} aufgebraucht wird, (die Zahl der resonanzverschluckten Neutronen ist von gleicher Größenordnung, wie die Zahl derjenigen, die die Kette fortsetzen), einen Energieakkumulator dar, der sich ebenso wie die Zerfallsprodukte chemisch abtrennen läßt. Im letzteren Falle aber muß das entstehende langlebige Isotop des Atomgewichts 239 selbst wieder Thermospaltung zeigen. Die Untersuchung der radioaktiven Elemente der verschiedenen Reihen, hat nämlich ergeben, wie auch theoretisch auf Grund des Modells von Bohr und Wheeler (2) zu erwarten ist, daß die zur Spaltung erforderliche Energie des Kerns in jeder Zerfallsreihe mit zunehmendem Atomgewicht abnimmt. In der (4n + 3) - Reihe ist nun schon bei U^{235} der Punkt erreicht, bei dem die Spaltungsenergie unter der Bindungsenergie des Neutrons liegt, also der Compound-Kern auch bei verschwindender kinetischer Energie des eingefangenen Neutrons gegen Spaltung instabil ist. Durch Aufnahme eines Neutrons kommt aber mit U^{239} wieder ein Kern dieser Reihe zustande, der sicher nicht stabiler gegen Spaltung sein kann, als U^{235}. Daher muß also ein entstehendes langlebiges Produkt der Masse 239 durch thermische Neutronen spaltbar sein. Jedes Neutron, das anstatt an U^{235} Spaltung zu bewirken von U^{238} eingefangen wird, schafft also einen neuen, durch thermische Neutronen spaltbaren Kern. Wir können daher eine Apparatur, die es gestattet, mit einem Energieumsatz an wägbaren Mengen U^{235} die Kettenreaktion ablaufen lassen, gleichzeitig als eine Isotppenumwandlungsapparatur ansehen. Der Vorteil gegenüber einer Isotopentrennungsapparatur ist aber der, daß das neugeschaffene Produkt, das ja eine Kernladung von 93 oder mehr hat, chemisch nicht mehr mit dem Uran identisch und daher mit gewöhnlichen chemischen Methoden abzutrennen ist. Da nun viel größere Mengen, nämlich das 139fache an U^{238} zur Verfügung stehen, so ist die Verwertbarmachung desselben als "Brennstoff" für eine Kettenreaktion ein für unsere Themenstellung viel wichtigerer Vorgang, als die Isotopentrennung, die bloß das U^{235} zu verwerten gestattet.

Für die Anregung zu dieser Arbeit und deren Ermöglichung danke ich Baron Manfred von Ardenne.

Berlin-Lichterfelde-Ost, den August 1941

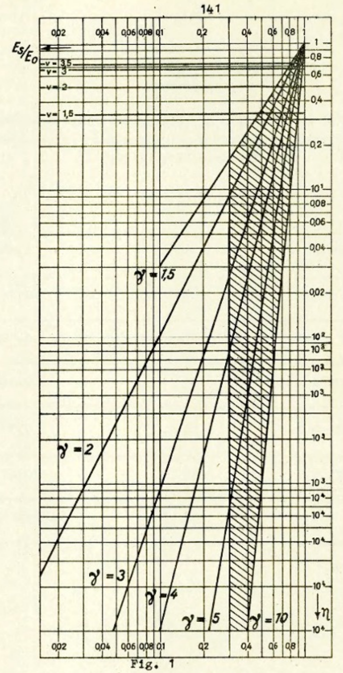

Fig. 1

Kernspaltung durch schnelle Neutronen. Wahrscheinlichkeit η eines Neutrons unter die kritische Energie der Kernspaltung abgebremst zu werden in Abhängigkeit vom Verhältnis E_s/E_0 (kritische Energie der Spaltung durch mittlere Primärenergie) sind die schrägen Geraden für verschiedene Werte von $\gamma = \sigma_s/\sigma_d \cdot \mu$. Das schraffierte Gebiet gibt die experimentellen Grenzen an, der eingezeichnete Punkt den wahrscheinlichen Wert. Die roten horizontalen Geraden geben den kritischen Wert an, für den gerade noch eine Kettenreaktion möglich ist, wenn die Zahl der Neutronen pro Spaltprozess zu angenommen wird. Damit die Kette nicht abreißt, muß der experimentelle Wert von unter der roten Geraden für den wahren Wert von v_s liegen. Je tiefer er darunter liegt, desto kleiner wird das kritische Volumen.

Copy No. 2 of 5 copies

30 April 1945

SUBJECT: Hechingen Area Operation

1. On Monday, 23 April 1945, the writers left Heidelberg and proceeded to Haigerloch where it was found that the targets had been secured by the Alsos Mission and were under guard. Since the fall of Hechingen was imminent, we went directly there.

2. The two Haigerloch targets - the experimental installation of the RFR and the Institute for Nuclear Physics Measuring Methods - were subsequently exploited by Lt. Col. Lansdale and the British representatives. The experimental pile, which contained no metal or heavy water, was photographed, dismantled and destroyed with explosives by this group. Approximately one and one-half tons of heavy water and one and one-half tons of uranium metal were subsequently found buried near Haigerloch and were evacuated by truck.

3. In Hechingen, the branch of the KWI for Physics was located and secured. All of the personnel, with the exception of Heisenberg, were present. He had left a week previously to join his family at Urfeld am Walchensee, Oberbayern. Of the personnel found at Hechingen, the following are the most important: von Weizsaecker, Wirtz, von Laue, Molière, Hoecker, Hiby, Sauerwein, Gysae, Bagge, Korsching, Bopp, Fischer and Menzer. Von Weizsaecker and Wirtz were interrogated, but in no great detail. The writers were told that all secret documents had been burned by government order. Following the capture at Tailfingen later of a complete set of secret reports, of which fact he was aware, Weizsaecker admitted that certain secret reports had been buried in a cesspool. They were recovered by Dr. Goudsmit. Neither Weizsaecker nor Wirtz was willing to discuss the uranium project in any detail. They said that this should be done by Heisenberg only with top ranking physicists on the American side, which he is quite willing and ready to do. His only reason for leaving Hechingen was to join his wife and six children.

Two interesting new isotope separation experiments were in progress at Hechingen - Bagge's velocity selector ("Isotopen Schleuse") and Korsching's diffusion apparatus. Both of these were dismantled and evacuated.

4. On Tuesday, 24 April, Bisingen was taken, and Forschungsstelle D of the Kaiser Wilhelm Gesellschaft was secured. Daellenbach, the Director, had gone to Switzerland in December 1944 and had not returned (he is a Swiss citizen). His assistant, Dr. Karl Weimer, was interrogated briefly. A 900,000 volt cascade generator, built by C.A.F. Mueller of Hamburg, was used to determine design data for a new type of cyclotron of 10,000,000

volts. Construction of a small experimental model had been started. On Friday, 27 April, Weimer was interrogated in detail by F. A. C. Wardenburg and David B. Griggs. Drawings and technical data and a patent specification were secured. A separate report on this subject, which is entirely unconnected with the TA project, is being prepared by Dr. Griggs.

5. Shortly after Tailfingen was captured on the morning of 25 April by the combat battalion of the Alsos Mission, the undersigned arrived at the headquarters of the K.W.I. für Chemie located in a knitting mill. All scientific personnel of Hahn's group were there, of which the following are the most important: Hahn, Mattauch, Strassmann, Erbacher, Klemm, Flammersfeld, Radoch, Seelmann-Eggebert, Waldmann and Wietig.

After talking with Dr. Hahn, it was determined that the K.W.I. für Chemie had three separate groups at Tailfingen led respectively by Hahn, Mattauch, and Erbacher. The latter two were sent for to be interrogated.

6. Dr. Hahn was very cordial and very cooperative. His group has been working on the separation, distribution and energy of the fission products of uranium. According to Hahn, the results of this work have all been published even though originally treated as secret. When asked about the purpose of this work, Dr. Hahn replied that a knowledge of the fission products is necessary to predict their effect on the operation of the pile. Hahn had, therefore, been given a very high priority for the work.

Hahn was also asked to express his general views on the future of the TA work as well as its applicability to military uses. He stated that, at present, the development of an atomic bomb is impossible and has been considered as such by the Germans since 1942. Hahn did, however, believe that the pile as an energy machine would be successfully developed in a few years. This energy machine, he explained, would produce element 93 which must decay to 94 (not yet discovered), and this latter element as well as a long-lived isotope of element 93 is believed to have the properties necessary for a bomb. The machine to produce these elements must, however, be developed first.

7. After the interrogation, Hahn conducted us through the laboratory. His file of about 150 secret reports on German TA work, including the Forschungsberichte of the RFR, was found intact. These reports were later catalogued and taken by Lt. Col. Lansdale to London for reproduction.

8. Dr. Erbacher showed us through his laboratories where they are working on the chemical separation of isotopes, on the protection of uranium from corrosion and on the separation of an active element from its inactive isotopes. They have developed a method of coating uranium with a monatomic layer using a copper ammoniate solution. This protects the metal from corrosion in water up to 150° C. Erbacher's group is also working on the effect of dust powder (?) in lungs.

9. Dr. Mattauch then showed us through his laboratories where they are working on the mass-spectrographic method of fission-product (or isotope) analysis. He has recently developed a new method of measuring geological age of the earth by determining the relative abundance of strontium isotopes

~~SECRET~~

in a mass spectrograph. One member of Mattauch's group, Dr. Klemm, has been working on a method of isotope separation by the electrolysis of a fused salt. It has not yet been proven feasible.

10. The following personnel have been evacuated to Heidelberg pending establishment of a permanent detention location: Hahn, Mattauch, von Weizsaecker, von Laue, Wirtz, Bagge and Korsching.

Figure D.358: James A. Lane and Frederic A. C. Wardenburg. 30 April 1945. SUBJECT: Hechingen Area Operation [NARA RG 77, Entry UD-22A, Box 168, Folder 202.2 LONDON OFFICE: Combined Intell Disc.].

[German reports captured by the U.S. Alsos Mission also show that there was wartime work on chemical methods for processing irradiated fission fuel and purifying different components from it. Unless otherwise noted, text for G-series captured German nuclear reports cited here consists of the English-language abstracts prepared by American scientists who studied the German reports.]

G-259. Otto Hahn and Fritz Strassmann. The Chemical Separation of Elements and Atomic Species Produced by Uranium Fission (General Part). 1944.

Introductory considerations on separation of U fission products are given. Extraction of U as nitrate is possible if amounts larger than several 100 g are irradiated, the other method is more advisable for amounts smaller than that: three methods are proposed for extraction of the remaining smaller amounts of U from the fission products, separation of the U as sodium pyrouranate by precipitation with a solution of caustic soda, precipitation by ammonium to ammonium pyrouranate, dissolving of this by surplus ammonium carbonate to uranium carbonate, and precipitation as sodium uranylacetate.

G-260. Otto Hahn and Fritz Strassmann. Chemical Separation of Uranium Fission Products. Halogens, Rare Gases, Earth Metals and Alkaline Earth Metals. 1944.

Distillation methods, precipitation by Ag ions, and solvent extraction for I and Br separation are reported in detail. Indirect identification of Xe and Kr proved less reliable than their direct identification in specially constructed counting tubes. Different tubes and methods of operation are illustrated. Indirect identification of halogens by determination of noble gases formed by halogen decay are given for Rb and Cs, Sr and Ba. Detailed extraction methods for the single elements are given for Zr, Nb, Mo, Tc, Sn, Sb, Te, Se, As, Ge, Ga, Zn, Co, and Ni. Isotopes intermediary between Br^{35} and Br^{39} could not be identified. A procedure to separate all fission products from a single sample of irradiated U concludes the report.

G-111. Josef Schintlmeister. The Placing in the Periodic Table of the Element with Alpha Rays of 1.8 cm Range. 1941.

See reports G-55 and G-112 for chemical identification of this element. Element can be atomic number 93 or 94 but its alpha decay energy and stability as regard beta decay shows it is not 93. It mass number is most likely 244 but it could be 246, or 242. This can be determined, for 244 and 242 can be split by thermal neutrons while 246 will require faster neutrons.

This element is precipitated by H_2S from strongly acid solutions and it does not form compounds in strongly oxidizing solutions (HNO_3 and H_2SO_4).

G-112. Josef Schintlmeister and Friedrich Hernegger. Further Chemical Investigation of an Element with Alpha Rays of 1.8 cm Range. 1941.

Some chemical properties of new element. Ammonia and sodium hydroxide precipitate about half the element. Carbonate precipitates it quantitatively. In distillation with nitric acid or hydrochloric acid the element is not distilled, but with sulfuric acid a high percentage of the element is distilled over. Hydrogen sulfide precipitates it quantitatively from strong acid solutions. Other chemical properties listed.

Josef Schintlmeister to Hermann Mark. 7. August 1945. [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-2 GERMANY: Personnel (Jan 45–Dec 45)] See document photos on pp. 3828–3829.

Die heute Nacht erfolgte Veroffentlichung der ersten technischen Anwendung der Uranspaltung nehme ich zum Anlass, Ihnen mitzuteilen, dass auch am II. Physikalischen Institut wahrend des Krieges an diesem Problem gearbeitet wurde. Ich selbst war aus diesem Grunde nie zur Wehrmacht eingeruckt. [...]

Die technische Ausnutzung der Atomkernenergien bei der Uranspaltung setzt sehr schwierige und sehr kostspielige Arbeiten voraus. Mit einigen Kilogrammen der neuen Elemente, die such unvergleichlich einfacher und billiger gewinnen lassen, wird sich aller Voraussicht nach ohne den bisher notigen Aufwand eine Atomkernmaschine bauen lassen, da zu erwarten ist, dass die Kernspaltung leichter als bei Uran eintritt und auch erheblich mehr Neutronen bei der Spaltung freiwerden, sodass die Kettenreaktion gut ablauft.

I would like to take tonight's publication of the first technical application of uranium fission [Hiroshima] as an opportunity to inform you that work on this problem was also carried out at the [Vienna] Second Physics Institute during the war. I myself was never drafted into the Wehrmacht for this reason. [...]

The technical utilization of nuclear energy in uranium fission requires very difficult and very expensive work. With a few kilograms of the new element [plutonium], which is incomparably easier and cheaper to obtain, it will in all likelihood be possible to build a nuclear device without the effort required to date, since it is to be expected that nuclear fission will occur more easily than with uranium and also that considerably more neutrons will be released during fission, so that the chain reaction will proceed smoothly.

Samuel A. Goudsmit to Horace K. Calvert. 5 September 1945. [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-2 GERMANY: Personnel (Jan 45–Dec 45)] See document photo on p. 3830.

1. Enclosed is a letter from a Dr. Schintlmeister who worked with Stetter in Vienna. I think that the contents of this letter should be called to the attention of the scientists working on the project back home just as soon as possible. There are some statements there which make it come nearer to the real thing than any other report that I have seen so far, even though it is mere speculation on his part and does not refer to any conclusive experiments. He seems to be aware of the importance of the transuranic elements.

2. The letter was given to Dr. [Charles P.] Smyth for the purpose of transmitting it to Professor H. Mark who is now at the Brooklyn Polytechnic Institute. It is, of course, not recommended that this letter be transmitted. A copy of this letter was given to the Military Government at Zell am See with the request that it be sent to Smyth. They, however, considered it unimportant and destroyed the letter. Smyth received this copy on a subsequent visit.

[Immediately after hearing the news of Hiroshima, Josef Schintlmeister wrote that throughout the war he had worked on a similar project involving a new element (plutonium), of which just a few kilograms would be sufficient for a nuclear device. He offered to help restart that work for postwar sponsors, alarming Samuel Goudsmit and other U.S. officials.]

Sehr geehrter Herr Professor!

Die heute Nacht erfolgte Veroffentlichung der ersten technischen Anwendung der Uranspaltung nehme ich zum Anlass, Ihnen mitzuteilen,dass auch am II.Physikalischen Institut wahrend des Krieges an diesem Problem gearbeitet wurde.Ich selbst war aus diesem Grunde nie zur Wehrmacht eingeruckt.

Sie erinnern sich noch, dass ich wahrend unserer gemeinsamen Expedition in den Kaukasus vor nunmehr 10 Jahren und auch auf manchen spateren Bergfahrten von der Suche nach dem unbekannten Element sprach,das Alphastrahlen von 2 cm Reichweite aussendet.Wahrend des ganzen Krieges habe ich uber dieses unbekannte Element gearbeitet. Durch hunderte Versuche ist erhartet,dass insgesamt sieben bisher unbekannte Alphastrahler vorliegen mit chemisch sehr verwandten Eigenschaften,der ganzen Sachlage nach liegen Transurane vor.Es gelang als Ausgangsmaterial bisher wertlose Abfallprodukte der Metallverhuttung aufzufinden, die in sehr grossen Mengen vorliegen.Die chemischen Eigenschaften sind in grossen Umrissen festgelegt und aller Wahrscheinlichkeit nach wird die Gewinnung der Transurane im technischen Masstabe keine Schwierigkeiten bieten.In letzter Zeit habe ich starke Praparate in der Hand gehabt,mit denen eine massenspektrographische Aufnahme bereits moglich gewesen ware.Rontgenspektren habe ich besonderer Verhaltnisse wegen nicht aufnehmen konnen;nach der radioaktiv gemessenen Starke der Endfraktionen waren sie zu erhalten gewesen.Die Arbeiten habe ich mit Dr. Hernegger als Chemiker begonnen und sie mit Professor Dr. Alfred Brukl weitergefuhrt.Brukl ist zwar ein vorzuglicher anorganischer. Analytiker,konnte sich aber doch mit der besonderen Eigenart des Problems nicht ganz befreunden,so dass die Arbeiten nicht in dem wunschenswerten und an sich moglichen Tempo vorangingen.

2 SECRET

Uber den Fortgang der Arbeiten habe ich in einigen Geheimberichten den vorgesetzten Dienststellen Mitteilung gemacht,wobei allerdings nicht alle Einzelheiten wiedergegeben sind.Uber die Arbeiten der letzten zwei Jahre habe ich keine Mitteilung verfasst und Aufzeichnungen hieruber existieren nicht mehr.Wahrend des letzten Jahres litt die Arbeit wegen der schwierigen Transportlage und der standigen Luftangriffe.

Die technische~~n~~ Ausnutzung der Atomkernenergien bei der Uranspaltung setzt sehr schwierige und sehr kostspielige Arbeiten voraus. Mit einigen Kilogrammen der neuen Elemente,die such unvergleichlich einfacher und billiger gewinnen lassen, wird sich aller Voraussicht nach ohne den bisher~~igen~~ notigen Aufwnad eine Atomkernmaschine bauen lassen,da zu erwarten ist, dass die Kernspaltung leichter als bei Uran eintritt und auch erheblich mehr Neutronen bei der Spaltung freiwerden,sodass die Kettenraktion gut ablauft.

Unter den gegebenen Verhaltnissen habe ich auf absehbare Zeit hinaus hier in Osterreich keine Moglichkeit, die Arbeit zu einem Abschluss zu bringen.Voraussichtlich sine noch zwei Jahre Forschungsarbeiten notwendig,um das erste Gramm der neuen Elemente in der Hand zu halten. Allerdings konnte in einem gut eingerichteten Laboratorium und bei der Mitwirkung sehr guter Anorganiker der Enderfolg rascher erzielt werden. Da nunmehr die Kernphysik in die Technik eingetreten ist, frage ich an, ob Sie geneigt waren,mir die Moglichkeit zu eroffnen, in Ihrem Laboratorium die Arbeiten fortzusetzen und zusammen mit Ihnen zum Abschluss zu bringen.Sie kennen mich ja durch viele Jahre und werden mir Glauben schenken,wenn ich Ihnen versichere,dass nicht vage Spekulationen verliegen sondern ein umfangreiches Tatsachenmaterial einen Erfolg in Aussicht stellt,dem wie die Dinge liegen,auch eine kommerzlelle Bedeutung zukommt.Wenn Sie meine Anregung aufgreifen wollten, ware ich daruber sehr glucklich; ich bin jederzeit bereit die Reise zu Ihnen anzutreten.Wenn es sich ermoglichen liesse, hatte ich gerne etwa zwei jungere Mitarbeiter mitgebracht.

Ihre Schwester habe ich im Februar dieses Jahres zuletzt gesehen. Ihr,sowie Ihrer Mutter ging es damals gut.Die Wehnung in der Strohgasse 22 ist total zerstort worden.Frau Baroni wurde bei einem der letzten Luftangriffe getotet,die beiden Kinder waren in einem anderen Keller und leben. Unsere Begleiter im Kaukasus hatten folgendes Scicksal:Baroni ist vermisst in Rumanien,wahrscheimlich in russischer Gefangenschaft. Ludwig Vorg ist in Russland gefallen,mein Bruder Peter ist seit dem Ruckzug der Truppen aus dem Kaukasus vermisst und vermutlich Partisanen in die Hande gefallen. Schwarzgruber ist am Kuban gefallen.Von den anderen Bekannten fielen Erwin Schlager. Primas Franzi ist an einem Nierenleiden gestorben.Von den Brudern Rossnern weiss ich nichts.Ich hatte drei Kinder,ausser Wolfgang noch /Dieter, vor einem Jahre kam Inge zur Welt.Dieter wurde am 19.Juni dieses Jahres in Alter von 5 1/2 Jahren von einem amerikanischen auto bei Kuchl uberfahren und war sogleich tot.Ich selbst wurde in Wien total ausgebombt und konnte nur einen geringen Teil meines Besitzes bergen.Meine Familie lebt bei Golling und entging so den Luftangriffen auf Wien.

Ich bitte Ihrer verehrten Frau Gemahlin meine besten Empfehlungen zu ubermitteln,ich lasse auch Ihre beiden Jungen Hans und Peter,die ja auch schon gross sein mussen,herzlich grussen.

Mit den besten Grussen
verbleibe ich Ihr.

MEMORANDUM:

TO : Major H. K. Calvert
Office of Military Attache
American Embassy
LONDON

1. One of my men, Dr. G. P. Kuiper, visited Göttingen recently and was given a lot of information by Houtermans. Houtermans handed him various documents dealing with the German opinion of the U-Bomb, Russian policy on the same subject, etc. You know my opinion of Houtermans, and I would not take his statements as correct, though the problem itself is, of course, of great importance. The documents in their entirety have not yet come into my hands - just a one page abstract written by Kuiper which I send on to you. Kuiper states that he has given a copy of this memorandum to Robertson who left for Berlin in order to clarify the future responsibilities on this topic. I personally should like to know whether Robertson has now taken over the TA project or whether he is doing it just on his own.

2. Enclosed is also a brainstorm of Houtermans' which, if it is correct, is probably not new. You might pass it on to the scientists on the project.

Figure D.362: Samuel Goudsmit to Horace K. Calvert. 10 September 1945 [NARA RG GOUDS, Entry UD-7420, Box 3, Folder "Historian's Office Inventory Control Job Goudsmit Box 4 Folder 6"]. "You know my opinion of Houtermans, and I would not take his statements as correct."

[The following document demonstrates that scientists in Germany understood how to convert Th-232 to make a U-233 bomb.]

Fritz Houtermans. 3 September 1945. How to use thorium for nuclear energy from fission. Typographical errors in the original document have been retained below. [NARA RG 77, Entry UD-22A, Box 173, Folder 60.22-1 RUSSIA: Research—TA (43–Jun 46)]

How to use Thorium for nuclear energy from fission.

Take pure thorium or thoriumoxide, mix to it some U 235 or Pu 239 separated from U238. The amount of U235 or 239 necessary will presumably be lower than 0.7%, because resonance capture in Th seems to be stronger than in U238. By neutron capture Th233 is formed. The mixture should be such that in heavy water, possibly also in metallic beryllium, or even BeO, or in graphite the chain reaction is just started, retarded only by resonance capture of Th232. It may be that the chain reaction will work only at low temperatures, if the width of the Th-resonance capture is given by Doppler-broadening. This will be true especially, the heavier the material is for slowing down the neutrons, i.e for graphite. It might be necessary to cool away even at low temperatures the energy released by the chain reaction, but any neutron lost will form an atom of Th 233, which decays with T=23 min to Pa 233, a body known to emit β-rays also and to decay into U 233. U 233 seems to have rather a long half life, and may be α-active. But from general considerations similar to those of Bohr-Wheeler, I should be rather think that U 233 has a fission treshold low enough that thermal neutrons will be able to make thermofission. Since you get weighable quantities of neutrons from the chain reaction in the separeted isotope U235 or 239 you will thus be able to enrich either U 233 to such an extent, that the chain reaction will start at normal temperatures or else to separete U 233 chemicall from the thorium mixture and use it as U235 or 239 as fuel for the machine.

How to use Thorium for nuclear energy from fission.

Take pure thorium or thoriumoxide, mix to it some U 235 or U 239 separated from U238. The amount of U235 or 239 necessary will presumably be lower than 0.7%, becuase resonance capture in Th seems to be stronger than in U238. By neutron capture Th233 is formed. The mixture should be such that in heavy water, possibly also in metallic beryllium, or even BeO, or in graphite the chain reaction is just started, retarded only by resonance capture of Th232. It may be that the chain reaction will work only at low temperatures, if the width of the Th-resonance capture is given by Doppler-broadening. This will be true especially, the heavier the material is for slowing down the neutrons, i.e. for graphite. It might be necessary to cool away even at low temperatures the energy released by the chain reaction, but any neutron lost will form an atom of Th 233, which decays with T= 23 min to Pa 233, a body known to emit β-rays also and to decay into U 233. U 233 seems to have rather a long half life, and may be α-active. But from general considerations similar to those of Bohr-Wheeler, I should be rather think that U 233 has a fission treshold low enough that thermal neutrons will be able to make thermofission. Since you get weighable quantities of neutrons from the chain reaction in the separeted isotope U235 or 239 you will thus be able to enrich either U 233 to such an extent, that the chain reaction will start at normal temperatures or else to separete U 233 chemicall from the thorium mixture and use it as U235 or 239 as fuel for the machine.

Figure D.363: Fritz Houtermans. 3 September 1945. How to use thorium for nuclear energy from fission [NARA RG 77, Entry UD-22A, Box 173, Folder 60.22-1 RUSSIA: Research—TA (43–Jun 46)].

Samuel Goudsmit and Frederic A. C. Wardenburg. 17 October 1944. Subject: Thorium Products taken to Auer Gesellschaft, Germany [NARA RG 77, Entry UD-22A, Box 163, Folder Australia]

The following information was obtained from M. Paul Gregory, acting Director of the Societé des Terres Rares, 67, Rue de Preny, Paris (17^o).

During the occupation the company was under the supervision of employees of the Auer Gesellschaft. The president of Auer, Dr. Quadebert, visited Paris occasionally. The man in direct charge of all Auer interests in occupied territory was Dr. Ihwe, who did much travelling.

The Germans showed at first only mild interest in Thorium. They did buy various rare earth compounds, probably for use in colored glasses. Early in 1944, however, they requisitioned all available Thorium sufate, namely about 95 tons. They took 85 tons, but left 10 tons for the French. During the occupation they had acquired about 850 tons of monazite, which is equivalent to about 86 tons of Thorium oxide.

The sudden interest in Thorium products is unusual, according to M. Gregory. He stated that is considered as a waste product in rare earth production. He claimed not to understand what the Germans wanted it for. (Dr. Blumenfeld, the director of the company, now in New York, had previously called our attention to the use of Thorium oxide in the Fischer-Tropsch process).

BIOS 675. *The Production of Thorium and Uranium in Germany.*

Metallic thorium and uranium were produced on a large scale in Germany by the reduction of their respective oxides with calcium using a calcium chloride flux. The major part of the production during the war came from Werk II of the Deutsche Gold- und Silber-Scheide-Anstalt (Degussa)[...]

Thorium oxide was supplied by Auer Gesellschaft, Berlin, which had large stock piles of Monazite sand, i.e., an enriched sand consisting mostly of Monazite, Magnetite, Zirconia, Thoria and Quartz. After reduction of the oxide, the thorium metal was returned to Auer Gesellschaft or in some cases sent under their control directly to the consumers[...] The uranium ore was coming from Czecho-Slovakia and Belgium Congo and was supplied from their stock piles by the Auer Gesellschaft for reproduction. [...]

Raw calcium, obtained under the form of large ingots, was melted under special conditions to obtain a pure metal free from oxide or nitride contamination. [...]

In re: Possibility of the Utilization of U-233 by the Enemy

COPY

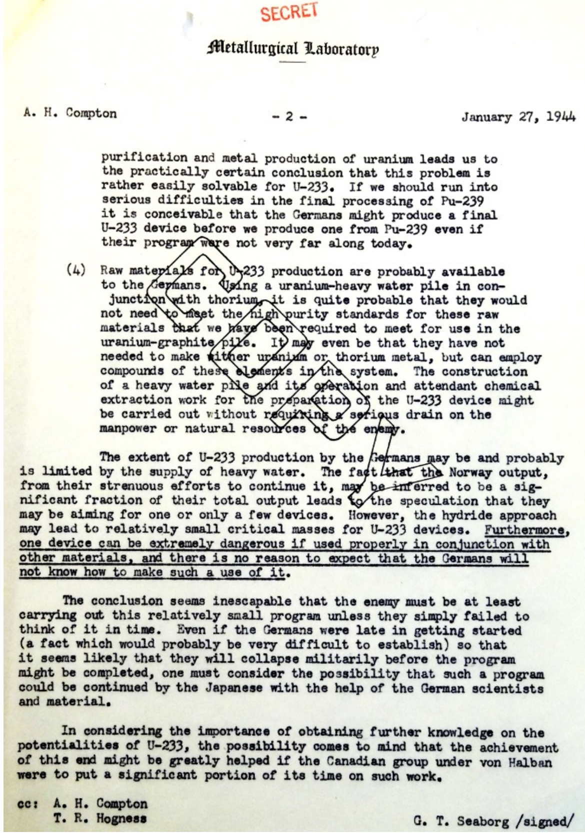
As you requested after our discussion of the above subject a month or so ago, I am summarizing some of the reasons which make it seem probable that the Germans may be able to produce at least one U-233 device within the near future. I believe this possibility should be considered since, if it is probable, it seems important that our High Command should be made cognizant of the fact in order that steps may be taken to distribute the governmental facilities of the Allied Powers in such a way that a single device alone could not deal a fatal blow. The possibility that plans for the utilization of U-233 may be near culmination by the enemy also makes it seem highly desirable that we should have enough work going on this problem so that we will be able to evaluate any developments which they may either employ or profess to be ready to employ.

Reasons which make it seem probable that the Germans may be preparing to use a U-233 device may be summarized as follows:

(1) We know that the Germans are making strenuous efforts to continue heavy water production in Norway, and there seems to be no other possible use for this material other than a nuclear power program. Likewise, we can infer that such efforts would not continue unless they had in mind an overall heavy water production program, in other places as well as Norway, calculated to make or have made an amount sufficient for their final objective within a reasonable length of time.

(2) U-233 can be separated from its parent thorium by relatively well known chemical processes. The isolation of U-233 may be very simple compared to that of Pu-239 or U-235. This is in part due to the fact that essentially only one radioactive species (Pa-233) is involved in the separation. I believe that the Germans could hand this separation problem to one of their large industrial chemical companies, who in turn would isolate the U-233 with only slight modifications in their existing equipment.

(3) The tolerance for light element impurities (which must be removed to prevent neutron production by the α,n reaction) is some ten-fold greater than that of Pu-239. Furthermore such purification as must be obtained can be tested with uranium, which, in contrast with Pu-239, would have been available for experiments during production of the actual U-233. Our own present knowledge of the



SECRET

Metallurgical Laboratory

A. H. Compton - 2 - January 27, 1944

purification and metal production of uranium leads us to the practically certain conclusion that this problem is rather easily solvable for U-233. If we should run into serious difficulties in the final processing of Pu-239 it is conceivable that the Germans might produce a final U-233 device before we produce one from Pu-239 even if their program were not very far along today.

COPY

(4) Raw materials for U-233 production are probably available to the Germans. Using a uranium-heavy water pile in conjunction with thorium, it is quite probable that they would not need to meet the high purity standards for these raw materials that we have been required to meet for use in the uranium-graphite pile. It may even be that they have not needed to make either uranium or thorium metal, but can employ compounds of these elements in the system. The construction of a heavy water pile and its operation and attendant chemical extraction work for the preparation of the U-233 device might be carried out without requiring a serious drain on the manpower or natural resources of the enemy.

The extent of U-233 production by the Germans may be and probably is limited by the supply of heavy water. The fact that the Norway output, from their strenuous efforts to continue it, may be inferred to be a significant fraction of their total output leads to the speculation that they may be aiming for one or only a few devices. However, the hydride approach may lead to relatively small critical masses for U-233 devices. Furthermore, one device can be extremely dangerous if used properly in conjunction with other materials, and there is no reason to expect that the Germans will not know how to make such a use of it.

The conclusion seems inescapable that the enemy must be at least carrying out this relatively small program unless they simply failed to think of it in time. Even if the Germans were late in getting started (a fact which would probably be very difficult to establish) so that it seems likely that they will collapse militarily before the program might be completed, one must consider the possibility that such a program could be continued by the Japanese with the help of the German scientists and material.

In considering the importance of obtaining further knowledge on the potentialities of U-233, the possibility comes to mind that the achievement of this end might be greatly helped if the Canadian group under von Halban were to put a significant portion of its time on such work.

Chicago, Illinois

Dear Dr. Compton:

COPY

The advantages possessed by 23 as compared with 49 from the standpoints of extraction, decontamination and purification are so noteworthy, as pointed out to me on previous occasions by Seaborg and more recently by Hogness, that it seems to me essential that work on those phases of the project related to 23 should be strengthened rather than abandoned. In my opinion, a well conceived process of the kind in question would be of inestimable value as an alternative in case of the possibility of failure with 49, which is not out of the question, or as a supplement if the latter is successful. It seems to me that the possibility that the entire project might be rescued by the availability of this alternative is good enough to make it necessary to develop it. In view of the proposed directive for discontinuance of this work I feel constrained to make this opinion known to you, even though I am not directly concerned.

There is one other subject, somewhat fantastic, upon which I should like to sound off. If it may be assumed that the Germans have or will have a weapon like ours, an answer to the question as to the most effective first use of it becomes pretty important. It seems quite possible to me that they could use it first against this country, daringly but successfully, say at Chicago. If so, this might be the most damaging thing they could do with it, in the long run. This possibility should, in my opinion, be canvassed by somebody competent to decide its feasibility and having the information necessary to do so. If it appears to be a real danger, steps should be taken to avoid being caught flat-footed.

Sincerely,

(signed) E. D. Eastman

In re: Possibility of the Utilization of U-233 by the Enemy

COPY

I am transmitting to General Groves and others in the Army who are concerned, copies of your memorandum on the possibility of utilization of 233 by the enemy. I want to thank you for bringing this matter to our attention.

I must say, however, that it is my own judgment that the U-233 program probably will require more time and industrial effort to develop to a conclusion than the 49 program upon which we are engaged. Also I do not see any strong reason to believe that the Germans are actually engaged upon a program of U-233 production.

With regard to the time and effort required, although it is probable that each unit will require less U-233 than 49, as you know roughly five times as much power must be dissipated per kilogram of U-233 as per kilogram of 49. To produce U-233 on an adequate scale would require also large quantities of heavy water whose preparation is a slow and expensive process. It is evident that the chemical separation process for U-233 will be somewhat simpler than for 49. It would, nevertheless require remote control shielded equipment and because of the long life of the radioactive protoactinium would presumably require a longer time than the separation of the 49.

Because of the real advantages of U-233, the desirability of keeping work alive on its investigation is clear. Your suggestion of encouraging the Canadians to follow this line is well worth following up. We also shall want to come back to its study when time permits.

Figure D.366: December 1943–February 1944 letters to and from Arthur H. Compton, demonstrating high-level U.S. concerns that Germany was breeding uranium-233 from thorium-232 [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)].

D.5.2 Known and Suspected Fission Reactors

[Pu-239 or U-233 could have been bred in a fission reactor. Np-237 [Sanchez et al. 2008] could also have been bred in a reactor (e.g., by knocking a neutron out of U-238), although it probably would have been more difficult to produce in quantity than Pu-239 or U-233 [Benedict et al. 1981].

There is evidence for several potential reactors in German-controlled territory, and one or more of those reactors may have been operational during the war (see map on p. 3841):

1. The reactor of Werner Heisenberg's group, first located at the Kaiser Wilhelm Institute for Physics in Berlin-Dahlem, and later moved to Haigerloch (pp. 3843–3853). This is by far the best known of the German fission reactors. With proper support and operation, it could have achieved criticality (a self-sustaining neutron chain reaction) during the war, but it never did [Goudsmit 1947; Groves 1962; Irving 1967; Pash 1969; Powers 1993; Walker 1989].

2. The reactor of Kurt Diebner's group, first located at Gottow/Kummersdorf, and later moved to Stadtilm (pp. 3854–3868). According to official histories, this reactor never achieved criticality during the war. In fact, there is some evidence that it may have achieved criticality in late 1944 in Gottow, and/or in March 1945 in Stadtilm [Karlsch 2005].

3. A reactor built and operated by the SS, likely in an underground facility in Thuringia, that was reported to have been operational in March 1945 (pp. 3865–3868).

4. A possible reactor and fuel reprocessing facility in the Bergkristall tunnel complex at St. Georgen/Gusen near Linz, Austria, that may have been operational during the war (pp. 3874–3920 and 4962–4970).

5. A possible reactor at Unterraderach near Friedrichshafen (on the coast of the Obersee Bodensee) that was reported to have been operational in 1944 (pp. 3921–3925).

6. A possible reactor at an underground facility in Berlin-Lichterfelde that was reported to have been operational in 1944 (pp. 3926–3928).

7. "Atomic reactors" that were reportedly located in East Prussia and that may have been operational until they were bombed by the Royal Air Force at the end of August 1944 (pp. 3928–3933).

8. A tightly guarded, heavy concrete installation at the I.G. Farben Leverkusen plant that might have been a fission reactor (pp. 3934–3935).

9. A possible fission reactor at Bodenbach/Krizik-Werke/Weser-Werke/Podmokly (pp. 3936–3937, 3987–3998).

10. Other possible sites for fission reactors (pp. 3938–3953)?

Figure D.367: Sites of known or suspected reactors for the German nuclear program.

If one or more fission reactors were functioning during the war, that could help explain the high priority that Germany placed on producing heavy water (an excellent neutron moderator for fission reactors) at numerous locations (p. 4027).

The Soviet Union demonstrated its first fission reactor (F-1) on 25 December 1946, only about 12 months after its captured German nuclear scientists were able to begin setting up the captured German nuclear materials (including at least 300 tons of German-produced uranium oxide, which fueled both F-1 and the larger second Soviet reactor for breeding Pu-239). If German scientists and German materials accomplished that feat so quickly after starting over in the Soviet Union after the war, they certainly could have done it in German territory during the war.

In addition to the potential reactors listed above, there were also a few small, subcritical fission piles that appear to have been used purely for experimental purposes, such as those built by Robert Döpel's team in Leipzig and Paul Harteck's team in Hamburg.]

1. The fission reactor of Werner Heisenberg's group

G-371. Alvin M. Weinberg and Lothar W. Nordheim. Memorandum on the state of knowledge in nuclear science reached by the Germans in 1945. 8 November 1945.

[Note: This was a U.S. report analyzing some of the German G-reports. The U.S. code name "P-9" meant heavy water; "P-9U" meant a heavy-water-moderated uranium reactor.]

We have just had an opportunity to read a few of the German Kernphysikalische Forschungsberichte. We are writing in order to correct what we believe to be a very prevalent misconception concerning the state of the art as known to the Germans in 1945. We will proceed by posing a number of relevant questions and then answering them insofar as we can from the few reports we have been allowed to see. Presumably when more reports are made available we will be able to document our statements more fully.

I. Did the Germans know the correct lattice dimensions for a P-9U system?

Via the grapevine we have heard rumors that the Germans were experimenting with plate lattices far too rich in U. Apparently these rumors were based on very early reports which are not yet available to us. At present, however, the answer to the above question is an unequivocal yes. The March 1944 "Forschungsberichte" contain a description of experiments on various lattice arrangements performed by Bothe and Fünfer. The experiments are integral ones in which the strength of a source is measured with and without the lattice in place. The main conclusion drawn from these experiments is "eine Kombination von 20 cm D_2O und 1 cm U-Metall der Dichte 18 (wird) etwas die günstigste sein . . . Bisher hat man wohl mit einem grösseren U-Bedarfgerechnet." This conclusion is exactly the same as that reached by us, on the basis of calculations in August 1943 (CP-923). The German work apparently was done at the same time as ours.

Plates seem to have been preferred because they were most convenient for experiments. The advantage of cubes was recognized as early as June 1943 (Höcker), and the use of cylinders had been suggested on technical grounds.

II. Did the Germans know the critical dimensions of the P-9 machine?

We have not had access to the reports in which critical size calculations are made. However, there are repeated references, in the reports available to us, of about 4 tons as the required amount of P-9. This figure is essentially correct.

The Laplacians measured by the Germans are of the order 1000×10^{-6} cm^{-2}. This value is in excellent agreement with ours. It indicates, and this is important, that the U metal used by them was about as pure as ours.

III. What was the state of German theory of the chain reaction?

Here we are badly hampered by the unavailability of the reports. What we do have shows:

(1) Calculation of optimal lattice dimensions was understood and followed pretty much the same lines as ours. The calculated results on P-9 spheres agree well with ours.

(2) The group model for reflector calculations was introduced in early 1944. This was a little later than the time we began to use it extensively.

(3) Generally we would say their approach was in no wise inferior to ours; in some respects it was superior.

IV. Why didn't the Germans succeed in establishing a chain reaction with P-9?

The answer is simple; they did not have sufficient P-9. The latest reference is to a 1.5 ton P-9 experiment. According to our estimates, with the volume ratio they used (20:1), they would have needed somewhat less than 4 tons.

V. Are there any "scientific secrets" concerning the design of the chain reaction which the Germans do not seem to have understood?

From the general state of the art as deduced from the few reports we have seen, we would say their understanding of the principles is comparable to ours. The only non-engineering "secrets" we can think of which might affect the design of a chain reaction is the poisoning by Xe^{135}, and possibly, the properties of Pu^{240}.

VI. What bearing does this have on publication of the parts of the PPR [Performance Progress Report (?)] dealing with principles of the chain reaction?

The Germans knew how to design a lattice which will work. From the practical standpoint this is all that matters. The details of elegant perturbation theory or transport theory (which would be contained in Vol. III) or the details of heat transfer calculations (Vol. IV) would tell them nothing essential to the determination of lattice dimensions. They already know how to calculate the optimum dimensions.

A question of ethics is raised by the existence of the German reports. In many cases useful information is contained therein. It is certainly extraordinary, in a scientific treatise, to attribute a given result to an American author without at the same time giving due credit to his German counterpart who is known to have also done the work. Such a situation will arise for example, in Vol. III in the discussion of the multi-group methods where the Germans have duplicated our work.

VII. What bearing does this have on the general question of our "secrets"?

On this we can presume to speak only as individuals.

The general impression from the German reports is that they were on the right track and that their thinking and developments paralleled ours to a surprising extent. The fact that they did not achieve the chain reaction is primarily due to their lack of sufficient amounts of heavy water.

In one of the reports a vivid description is given of the German efforts in this respect. The heavy water factories in Norway were designed for a capacity of 3–4 tons a year and were successfully operating during part of 1942 and 1943. This capacity would have been sufficient for the construction of a pile. However, the production was interrupted by sabotage and finally the main factory was destroyed by a bombing attack. Toward the end of 1944 plans were made to initiate production of heavy water in Germany and to use enriched uranium in order to reduce the material requirements.

It is also fairly clear that the total German effort was on a very considerably smaller scale than the American effort. This may be due to the strained German economy or to the less favorable attitude of their government. The fact remains that an independent group of scientists, of much smaller size than ours, operating under much more adverse conditions achieved so much.

We must proceed therefore on the basis that anyone knowing what is in the German reports can establish a chain reaction, provided he has sufficient materials. The Smyth report will give additional very helpful hints. The time when others can establish a chain reaction is therefore no longer a matter of scientific research but mostly a matter of procurement. The policies of our authorities must, it seems to us, be formulated with a clear realization of these facts.

Via the grapevine we had heard rumors that the Germans were experimenting with plate lattices far too rich in U. Apparently these rumors were based on very early reports which are not yet available to us. At present, however, the answer to the above question is an unequivocal yes. The March 1944 "Forschungsberichte" contain a description of experiments on various lattice arrangements performed by Bothe and Fünfer. The experiments are integral ones in which the strength of a source is measured with and without the lattice in place. The main conclusion drawn from these experiments is "eine Kombination von 20 cm D_2O und 1 cm U-Metall der Dichte 18 (wird) etwa die günstigste sein . . . Bisher hat man wohl mit einem größeren U-Bedarf gerechnet." This conclusion is exactly the same as that reached by us, on the basis of calculations in August 1943 (CP-923). The German work apparently was done at the same time as ours.

Plates seem to have been preferred because they were most convenient for experiments. The advantage of cubes was recognized as early as June 1943 (Höcker), and the use of cylinders had been suggested on technical grounds.

II. Did the Germans know the critical dimensions of the P-9 machine?

We have not had access to the reports in which critical size calculations are made. However, there are repeated references, in the reports available to us, of about 4 tons as the required amount of P-9. This figure is essentially correct.

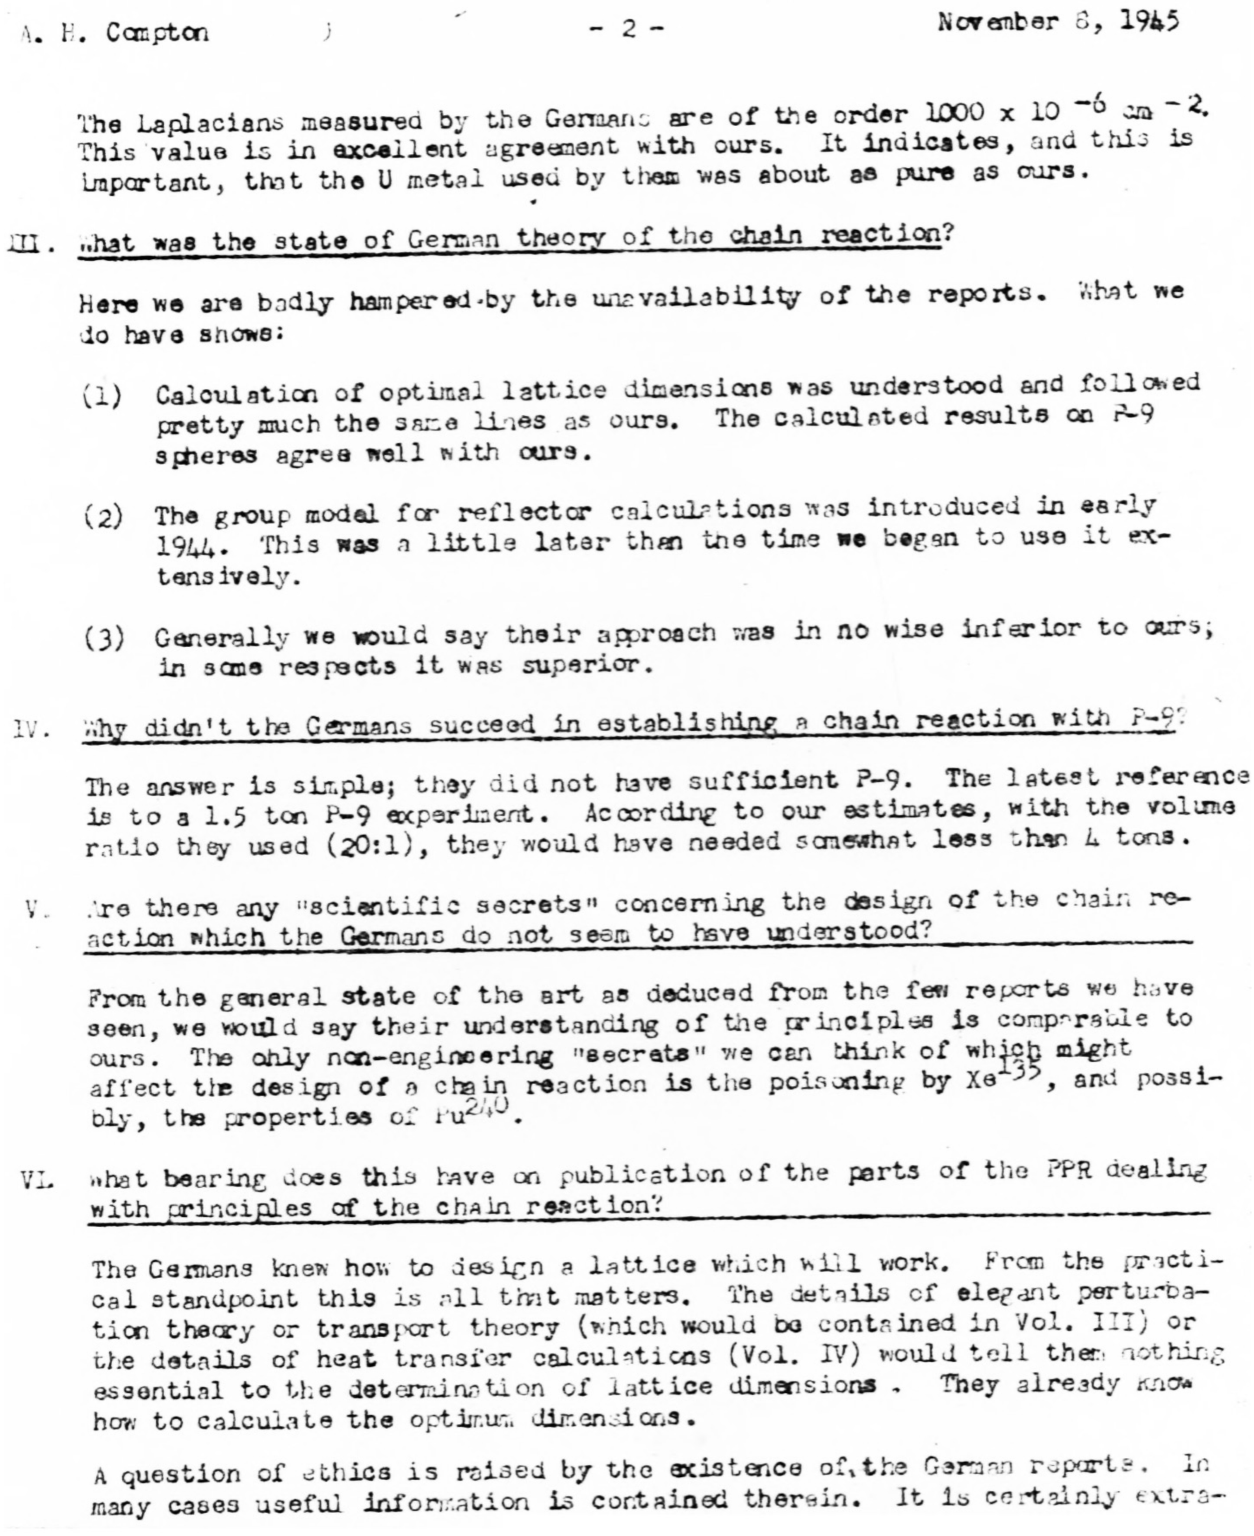
Figure D.368: Alvin M. Weinberg and Lothar W. Nordheim. Memorandum on the state of knowledge in nuclear science reached by the Germans in 1945. 8 November 1945 [G-371].



A. H. Compton - 2 - November 8, 1945

The Laplacians measured by the Germans are of the order 1000×10^{-6} cm^{-2}. This value is in excellent agreement with ours. It indicates, and this is important, that the U metal used by them was about as pure as ours.

III. What was the state of German theory of the chain reaction?

Here we are badly hampered by the unavailability of the reports. What we do have shows:

(1) Calculation of optimal lattice dimensions was understood and followed pretty much the same lines as ours. The calculated results on P-9 spheres agree well with ours.

(2) The group model for reflector calculations was introduced in early 1944. This was a little later than the time we began to use it extensively.

(3) Generally we would say their approach was in no wise inferior to ours; in some respects it was superior.

IV. Why didn't the Germans succeed in establishing a chain reaction with P-9?

The answer is simple; they did not have sufficient P-9. The latest reference is to a 1.5 ton P-9 experiment. According to our estimates, with the volume ratio they used (20:1), they would have needed somewhat less than 4 tons.

V. Are there any "scientific secrets" concerning the design of the chain reaction which the Germans do not seem to have understood?

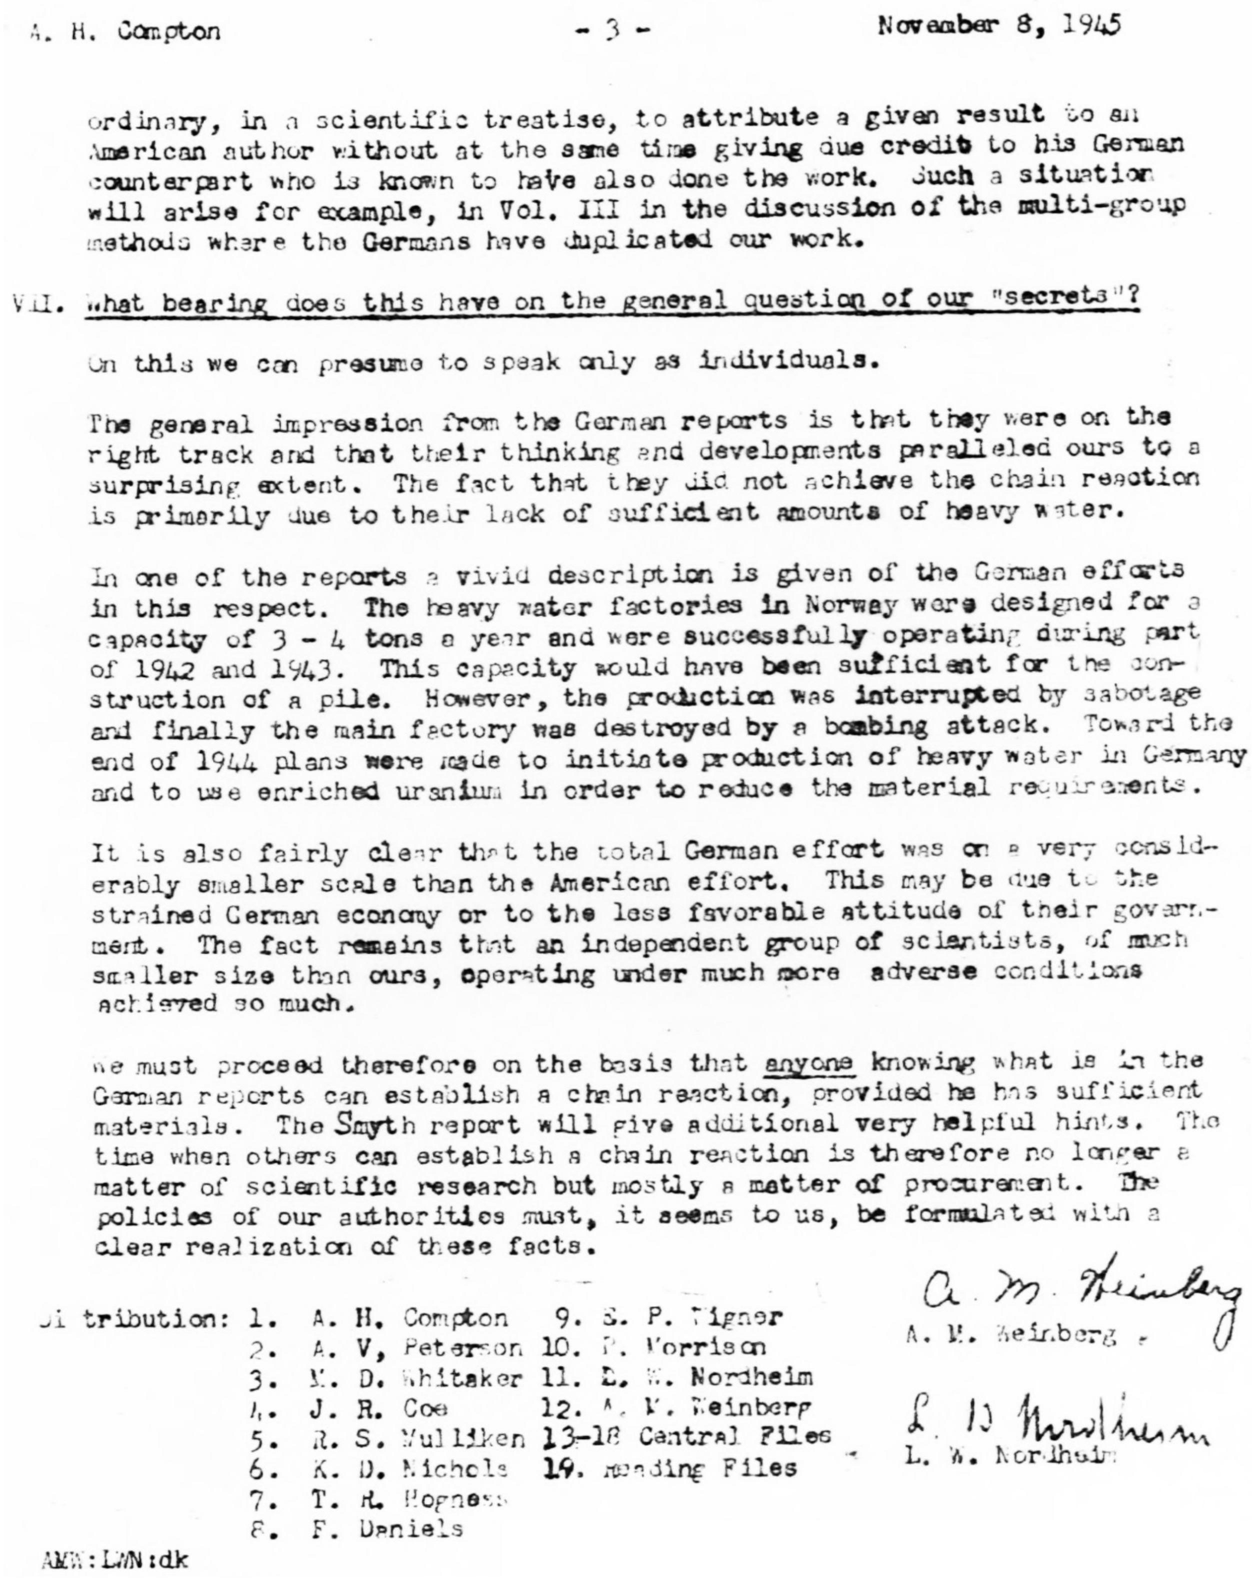
From the general state of the art as deduced from the few reports we have seen, we would say their understanding of the principles is comparable to ours. The only non-engineering "secrets" we can think of which might affect the design of a chain reaction is the poisoning by Xe^{135}, and possibly, the properties of Pu^{240}.

VI. What bearing does this have on publication of the parts of the PPR dealing with principles of the chain reaction?

The Germans knew how to design a lattice which will work. From the practical standpoint this is all that matters. The details of elegant perturbation theory or transport theory (which would be contained in Vol. III) or the details of heat transfer calculations (Vol. IV) would tell them nothing essential to the determination of lattice dimensions. They already know how to calculate the optimum dimensions.

A question of ethics is raised by the existence of the German reports. In many cases useful information is contained therein. It is certainly extra-

Figure D.369: Alvin M. Weinberg and Lothar W. Nordheim. Memorandum on the state of knowledge in nuclear science reached by the Germans in 1945. 8 November 1945 [G-371].



A. H. Compton - 3 - November 8, 1945

ordinary, in a scientific treatise, to attribute a given result to an American author without at the same time giving due credit to his German counterpart who is known to have also done the work. Such a situation will arise for example, in Vol. III in the discussion of the multi-group methods where the Germans have duplicated our work.

VII. What bearing does this have on the general question of our "secrets"?

On this we can presume to speak only as individuals.

The general impression from the German reports is that they were on the right track and that their thinking and developments paralleled ours to a surprising extent. The fact that they did not achieve the chain reaction is primarily due to their lack of sufficient amounts of heavy water.

In one of the reports a vivid description is given of the German efforts in this respect. The heavy water factories in Norway were designed for a capacity of 3 - 4 tons a year and were successfully operating during part of 1942 and 1943. This capacity would have been sufficient for the construction of a pile. However, the production was interrupted by sabotage and finally the main factory was destroyed by a bombing attack. Toward the end of 1944 plans were made to initiate production of heavy water in Germany and to use enriched uranium in order to reduce the material requirements.

It is also fairly clear that the total German effort was on a very considerably smaller scale than the American effort. This may be due to the strained German economy or to the less favorable attitude of their government. The fact remains that an independent group of scientists, of much smaller size than ours, operating under much more adverse conditions achieved so much.

We must proceed therefore on the basis that anyone knowing what is in the German reports can establish a chain reaction, provided he has sufficient materials. The Smyth report will give additional very helpful hints. The time when others can establish a chain reaction is therefore no longer a matter of scientific research but mostly a matter of procurement. The policies of our authorities must, it seems to us, be formulated with a clear realization of these facts.

AMW:LWN:dk

Figure D.370: Alvin M. Weinberg and Lothar W. Nordheim. Memorandum on the state of knowledge in nuclear science reached by the Germans in 1945. 8 November 1945 [G-371].

[Alvin Weinberg and Lothar Nordheim were experts in the U.S. fission reactor program. There are several important points regarding their memo:

- Even among the well-informed personnel of the U.S. Manhattan Project and over half a year after the war ended in Europe, there was a "very prevalent misconception" that the Germans had a poor understanding of applied nuclear physics. That misconception was apparently propagated by people such as Samuel Goudsmit, and has remained widespread ever since, despite this authoritative U.S. scientific memo stating that that misconception was entirely false.

- Weinberg and Nordheim, two high-ranking people in the U.S. Manhattan Project writing 6–12 months after the U.S. Alsos Mission had retrieved the relevant reports from Europe, repeatedly protested about the "few [German] reports we have been allowed to see," and that "we have not had access to the reports." Do those statements indicate that the United States was concealing German reports even from its leading Manhattan Project scientists, or that the United States was taking over 6–12 months before finally getting those reports to its leading scientists? If so, why was the United States suppressing information about the German nuclear program? Alternatively, if Weinberg and Nordheim had all the German reports that Alsos captured, their complaints suggest that a large number of relevant reports had been destroyed or hidden by the Germans.

- "The Germans knew how to design a [fission reactor] lattice which will work," "the German work apparently was done at the same time as" the U.S. work, "their approach was in no wise inferior to" the U.S. approach, and "in some respects it was superior."

- That equivalent work was achieved by a German group (apparently meaning the Kaiser Wilhelm Institute group led by Werner Heisenberg) that was much smaller than the corresponding American program. That shows great ability on the part of the German scientists, but it also demonstrates that Weinberg, Nordheim, and other high-ranking U.S. officials were unaware of all of the other parts of the German nuclear program—the large majority of the program.

- Allied sabotage and bombing of the heavy water factories in Norway (not any German lack of scientific ability) greatly delayed operation of a fission reactor in Germany.

- Weinberg and Nordheim were aware of heavy water production in Norway, and of German plans to produce heavy water elsewhere. Since their knowledge was admittedly very incomplete, it is possible that significant amounts of heavy water were actually produced elsewhere.

- Although Weinberg and Nordheim were unaware of a German pile that achieved a chain reaction, they admitted that their knowledge was very incomplete; it is possible that there was a German chain reaction that was unknown to these and perhaps even all U.S. officials.

- Weinberg and Nordheim essentially stated that it would be unethical for the United States to give public credit for applied nuclear physics innovations to scientists working in the wartime U.S. program but not to scientists from the wartime German program who were documented to have made the same (or better) innovations. That is in fact what the United States did and has continued to do.]

English translation of Walther Gerlach. 2 January 1945. Citation for Award of the War Service Cross First Class with Swords to Dr. K. DIEBNER, Member of the Board of Works. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1—GERMANY—Research—TA—(1943–June 1946)]

After uranium fission by means of neutrons became known back in 1939, Dr. Kurt Diebner, Member of the Board of Works, pointed out the importance of this discovery as a possible source of energy and was thereupon ordered by his superiors to form an association which was first made a part of Army Ordnance but which is now subordinated to the Deputy for Nuclear Physics. Within the framework of this Association, he and his own work-group took part in the experiments.

The geometric arrangement (cube arrangement) employed on the basis of his deliberations has turned out to be the most successful arrangement yet hit upon, although at the time ranking scientists saw nothing particularly significant in it; for example, with only one-third the supply of uranium and heavy water, he succeeded in achieving the same results that Prof. Bothe and Prof. Heisenberg did employing other geometrical arrangements. Diebner got a neutron increase of 106% with his experimental model; that is, he achieved a most efficient production of energy. The scope of the arrangement was limited because of the amount of material available to him at the time.

The results achieved by his work-group were so decisive that the cube arrangement is now employed in a large-scale experiment in which, in Prof. Heisenberg's opinion, a practicable uranium burner from the available supply of D_2O and metallic uranium is anticipated, so far as large-scale experiments can be judged with certainty from laboratory efforts.

[Publicly, after the war Samuel Goudsmit of the U.S. Alsos Mission and Leslie Groves of the Manhattan Project denigrated Kurt Diebner as being far inferior to Heisenberg in scientific talent, and in fact as being mainly an administrator and not a scientist.

Privately they found this document that proved that Diebner had been given a formal award by Walther Gerlach (an impeccable physicist, and presumably a good judge of physics) for doing extensive scientific research, and for achieving much better results than Werner Heisenberg. Markings on the document show that U.S. officials responded to this document by classifying it Top Secret and burying it in their files. See document photo on p. 3855.]

TRANSLATION

Citation for Award of the War Service Cross First Class with Swords to Dr. K. DIEBNER, Member of the Board of Works

After Uranium fission by means of neutrons became known back in 1939, Dr. Kurt DIEBNER, Member of the Board of Works, pointed out the importance of this discovery as a possible source of energy and was thereupon ordered by his superiors to form an association which was first made a part of Army Ordnance but which is now subordinated to the Deputy for Nuclear Physics. Within the framework of this Association, he and his own work-group took part in the experiments.

The geometric arrangement (cube arrangement) employed on the basis of his deliberations has turned out to be the most successful arrangement yet hit upon, although at the time ranking scientists saw nothing particularly significant in it; for example, with only one-third the supply of Uranium and Heavy-Water, he succeeded in achieving the same results that Prof. Bothe and Prof. Heisenberg did employing other geometrical arrangements. DIEBNER got a neutron increase of 106% with his experimental model; that is, he achieved a most efficient production of energy. The scope of the arrangement was limited because of the amount of material available to him at the time.

The results achieved by his work-group were so decisive that the cube arrangement is now employed in a large-scale experiment in which, in Prof. Heisenberg's opinion, a practicable Uranium-burner from the available supply of D_2O and metallic Uranium is anticipated, so far as large-scale experiments can be judged with certainty from laboratory efforts.

/s/ Walther Gerlach

In Obernessar Kreis Weissenfels
Residence: Berlin-Charlottenburg 5,
Schloss Str. 4a

Figure D.375: English translation of Walther Gerlach. 2 January 1945. Citation for Award of the War Service Cross First Class with Swords to Dr. K. DIEBNER, Member of the Board of Works. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1—GERMANY—Research—TA—(1943–June 1946)]

[Leslie Groves even wrote a secret 1946 memo stating that Diebner "has a pretty good grasp of the German project" and explicitly recognizing that he was among the handful of "those German scientists of outstanding ability in the field of nuclear physics and chemistry who, by their past reputation and present knowledge, would be of more value to the national interest of this country if they could be employed here rather than in any other country. [...I]t is extremely important that these persons be prevented from giving their services to a potential enemy of the United States" (p. 4807).

In 1939, Kurt Diebner may well have been the only person on Earth whose scientific expertise included all three of the following:

1. TNT implosion bomb designs ("hollow-charge explosives").
2. Fission chain reactions (proposals for uranium reactors and bombs).
3. High-energy-induced fusion reactions ("high-voltage particle accelerator for atomic transformations").

Those are the three major elements of the German nuclear device that was apparently tested by March 1945 (see p. 4485), or of modern nuclear bombs.

Likewise, Diebner occupied leadership roles that included the Army (Heereswaffenamt), Kaiser-Wilhelm Institute for Physics, Reich Research Council (Reichsforschungsrat), and the SS (when the SS controlled most research in the later stages of the war, if not earlier), and that spanned the entire German nuclear program from its very first meetings in 1939 in Berlin to the last days of the war in May 1945 in Thuringia.

Thus Diebner was one of the most important people in the German nuclear program, and possibly even the single most important person.

However, the false public depictions of Diebner's abilities by Samuel Goudsmit and Leslie Groves after the war were highly effective, and most historical books and documentaries for the last 75+ years have unquestioningly followed their lead in treating Diebner as a minor, peripheral official or even a scientific loser.]

Frederic A. C. Wardenburg, Stadtilm Operation, 30 April 1945 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)].

I. Instructions have been received to forward all captured TA documents to Washington for final analysis. No further analysis of Stadtilm documents will, therefore, be made by the Alsos Mission.

II. For the benefit of Washington personnel who will study the documents, the following summary is given of classification already started on this side:

(a) The material consists of unfiled papers, mainly technical data and reports, and of correspondence files and folders. Each of these file folders has been numbered on the back. Many of them have been read and an index of the important material made on separate cards.

(b) Now folders with the following general subject titles have been set up:

1. Organization
2. Financial
3. Pile experiments
4. Heavy Water
5. Uranium
6. Ultra centrifuge
7. Isotope Separation Other
8. Betatron
9. Medical
10. Miscellaneous
11. KWI for Chemistry
12. Personnel
13. Instruments & Measurements
14. Target Data
15. Non-TA General Intelligence

(c) Some of the original files have been stripped of important material which has been put in the above folders according to the subject. Cards for these folders which have been [illegible] but not yet classified are included in the envelope marked "Folders [illegible] done." Folders for [illegible] cards appear in neither envelope have not yet been read.

[Tube Alloy or TA was the Allied code name for uranium.

Where are these files now?]

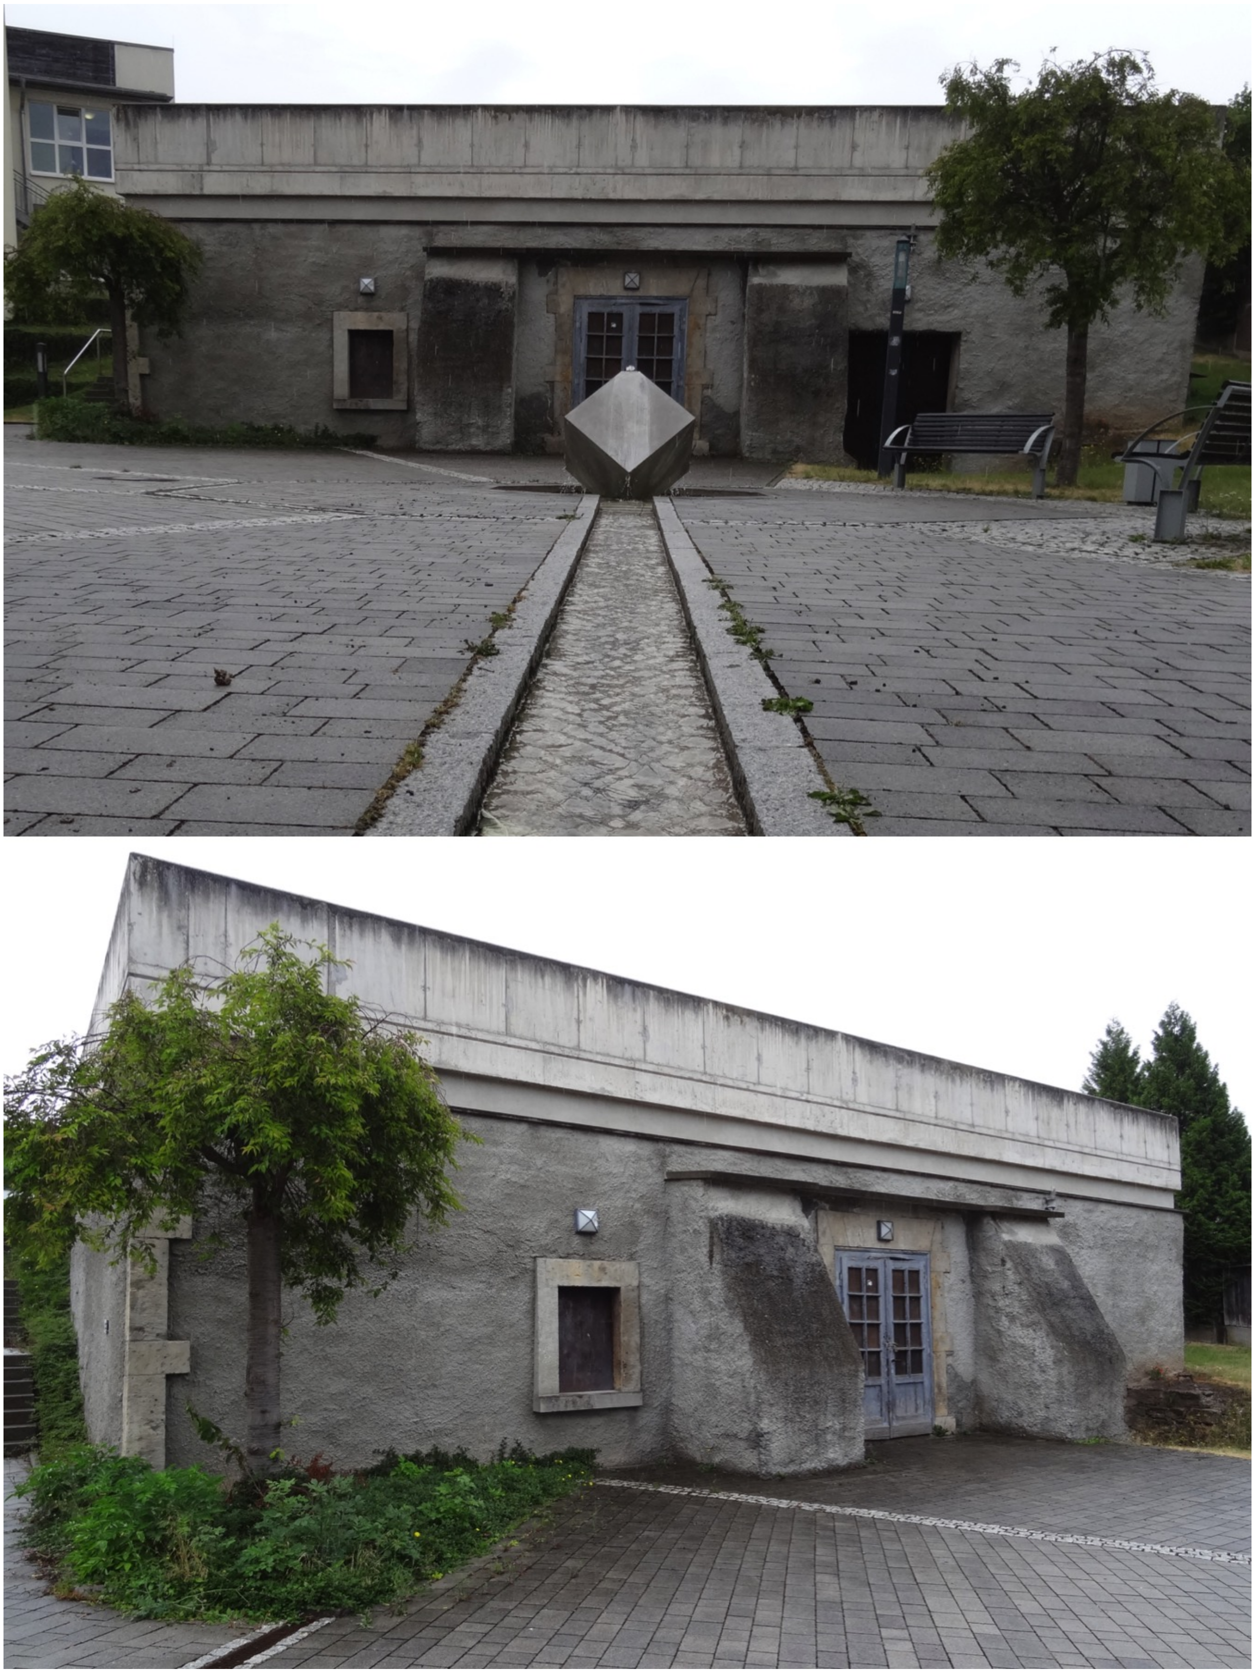

Figure D.381: The former Atomkeller in Stadtilm. Note the modern cube sculpture and water fountain to commemorate Diebner's experiments with uranium cubes and heavy water.

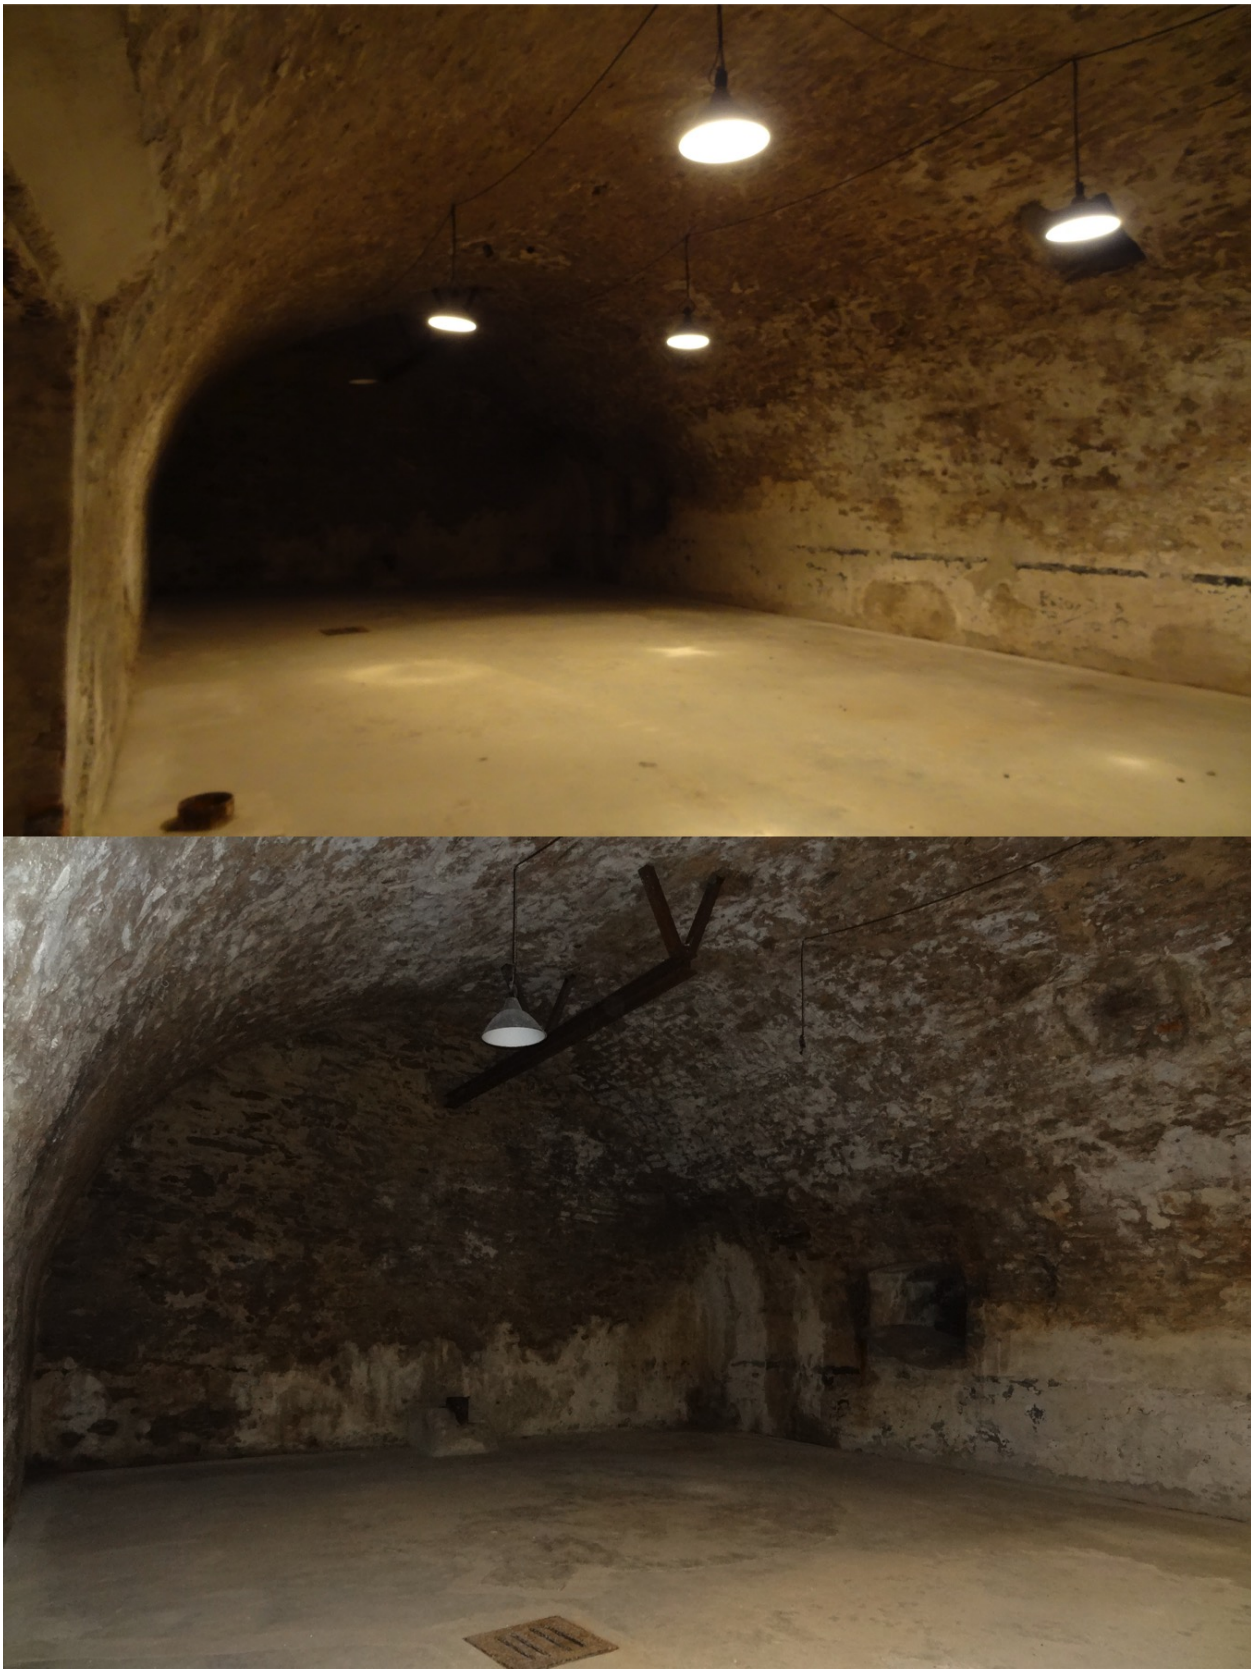

Figure D.382: The former Atomkeller in Stadtilm. In the lower photo, note the circular pit in the floor, now filled in with concrete, which once held the heavy water with uranium cubes suspended in it from the overhead beam.

Werner Grothmann on reactor breeding of Pu-239 (and U-233) [Krotzky 2002]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

[S. 40] Es gab klare Erkenntnisse, dass nicht alleine das Uran als Sprengstoff dienen konnte sondern auch Plutonium und weitere Stoffe, da kenne ich mich aber noch weniger aus als bei diesen Bezeichnungen. Jedenfalls ist wohl 1943 klar geworden, dass man mit Plutonium eine große Sache machen kann. Es war aber so, dass die Erzeugung ganz schwierig sein würde.

[p. 40] There was clear evidence that not only uranium could serve as an explosive, but also plutonium and other substances, about which I know even less than these names. In any case, it was clear in 1943 that one could do a great deal with plutonium. It was the case, however, that production would be quite difficult.

[S. 43] Ich vermute, dass es bei der Plutonium-Forschung zwischen einzelnen Wissenschaftlern eine Konkurrenz gab. Konkret kann ich dazu sagen, dass Diebner in einem Gespräch mit dem Chef [Himmler], das ganz kurzfristig angesetzt war betont haben muß, ich war ja bei solchen Gesprächen nie dabei, höchstens wenn es darum ging, was unsere Leute an begleitenden Maßnahmen leisten sollten, aber das hatte dann ja nichts mit der Forschung zu tun, also da gab es ein Gespräch mit Diebner, als sein Reaktor in Betrieb gegangen war, wo er sich über die Möglichkeiten geäußert hatte, bald richtige Bomben zu bauen. Das wussten wir schon, wenn ein Atomreaktor läuft, ist es viel leichter, Material für die Bombe zu erhalten. [...] Das weiß ich noch ganz genau, dass Himmler danach eine Besprechung hatte bei der angeregt worden war, eine Verbindung zwischen Kammler und jemand von den Physikern zu schaffen, damit man die Bedingungen besprechen konnte, die man braucht, wenn man einen neuen Reaktor einrichten will. Was danach gemacht worden ist, weiß ich nicht, mir ist nur bekannt, dass unser eigener Reaktor auch noch laufen lernte, das war ein großer Tag für uns, leider war das aber schon kurz vor Kriegsende, deshalb konnte das nichts mehr bewirken. [...] Zu Diebner muß ich aber noch sagen, dass ich nicht sicher bin, ob sein Reaktor von ihm oder von seinen Leuten so geregelt worden ist, daß der deshalb angelaufen ist. Es war ja so, daß wir erfuhren, daß es ja einen Unfall gegeben hatte. Ich weiß nicht, war es ein Unfall im Betrieb, oder hat es einen Unfall gegeben, bei dem das Ding losging. Ich hörte da verschiedene Gerüchte.

[p. 43] I suspect that there was competition among individual scientists in plutonium research. In concrete terms, I can say that there was a conversation with Diebner and the boss [Himmler], which had been scheduled at very short notice; I was never present at such conversations, at most when it came to what our people were supposed to do in accompanying measures that had nothing to do with the research. So there was a conversation with Diebner when his reactor went into operation, where he himself talked about the possibilities to build real bombs soon. We already knew that when an atomic reactor is running, it is much easier to get material for the bomb. [...] I remember that Himmler had had a meeting to create a connection between Kammler and someone from the physicists to discuss the conditions needed to set up a new reactor. What happened afterwards, I do not know, I only know that our own reactor was still running, that was a great day for us, but unfortunately it was already shortly before the end of war, so that nothing more could be done. [...] Regarding Diebner, however, I must say that I am not sure whether his reactor was controlled by him or by his people, which is why it started. It was true that we learned that there had been an accident. I do not know, it was an accident in the plant, or there was an accident, at which the thing went off. I heard different rumors.

[S. 31] Es gab dann auch noch ein Unglück ohne schlimme Folgen in Gottow bei Diebner. Dem ist sein Reaktor vielleicht durchgegangen, wie ich ja sagte. Das war möglicherweise die erste wirkliche Kettenreaktion auf der Welt, die sich selbst erhalten hat. Leider ließ sie sich nicht stoppen.	[p. 31] There was then also an accident without bad consequences in Gottow with Diebner. His reactor may have run away, as I said. This was perhaps the first real chain reaction in the world that sustained itself. Unfortunately it did not stop.
[S. 8] Unser Reaktor, der im März 45 anlief, war ja lange vorher schon eingebaut worden und auch nur noch mit viel Glück in Betrieb gegangen.	[p. 8] Our reactor, which started in March 45, had already been installed a long time before and had only just started with good luck.
[S. 43] Ich bin mir bis heute fast sicher, dass zum Beispiel bis jetzt nur ganz wenige wirklich etwas über unseren eigenen Atomreaktor wissen und dass der wirklich gelaufen ist. Die Konstruktion war schon sehr modern, das hat Diebner doch begeistert, weil es seine Ideen ja letztlich nochmals bestätigt hatte und er hatte ja zuvor schon Erfahrungen mit seinem Reaktor gehabt.	[p. 43] I am still almost certain that, for example, only very few really know something about our own nuclear reactor and that it really ran. The construction was already very modern, Diebner was enthusiastic about that, because it had finally confirmed his ideas and he had already had experience with his reactor.

[As potential fission fuels that were known during the war, Grothmann mentioned uranium [235], plutonium [239], and "other substances, about which I know even less than these names"—probably a reference to transmuting thorium-232 into uranium-233.

Grothmann knew of at least two fission reactors that had gone critical during the war:

1. The Diebner group's reactor, which went critical and actually had an accident before it could be stopped. That incident apparently occurred in late 1944 while the reactor was still at Gottow.

2. A completely separate reactor that was directly operated by the SS. According to Grothmann, that reactor first became operational in March 1945, but it had been built quite some time before that. Its "construction was already very modern," which suggests that the SS reactor was designed to breed fuel for nuclear weapons and not simply to be a small initial science experiment to achieve criticality. Although Grothmann did not specify a location for this SS reactor, it may have been in an underground installation somewhere in Thuringia, since most of Grothmann's knowledge in the interview was focused on nuclear and rocket research at underground installations in Thuringia.]

Helmut J. Fischer. 1987. *Hitler und die Atombombe: Bericht eines Zeitzeugen.* pp. 77–78.

Es war wohl der letzte Tag im März 1945, als am frühen Morgen Dr. Graue vom Kaiser-Wilhelm-Institut für Physikalische Chemie und Elektrochemie in meinem Büro erschien. “Die Uranmaschine läuft”, berichtete er aufgeregt und bat mich zu seinem Chef, Prof. Thiessen, der in der Nacht zuvor einen Telefonanruf von Gerlach erhalten hatte. Ich verständigte meinen vorgesetzten Gruppenleiter Dr. Spengler, und bald saßen wir zu viert beieinander in Thiessens Institut: Thiessen, Graue, Spengler und ich. Das Telefongespräch, von dem Thiessen berichtete, war offenbar unter großen Mühen zustande gekommen, die Verständigung war sehr schlecht gewesen. Immerhin ergaben sich aus Gerlachs Anruf zwei wichtige Nachrichten. Die erste meldete den großen Erfolg mit einer kritischen Uranmaschine. Die zweite Nachricht, die Gerlach mir übermitteln wollte, bezog sich auf die Gefährdung der Forschungsstätte in Stadtilm durch das Vorrücken der amerikanischen Truppen auf Thüringen.

Hier muß ich nun aus dem, was mir später bekannt wurde, hinzufügen, daß Gerlachs übergroße Freude über den erfolgreichen Versuch mit einer Uranmaschine berechtigt, seine Nachricht aber nicht ganz richtig übermittelt worden war. Die kritische Uranmaschine war noch nicht fertig, sondern nur “beinahe fertig”. Es fehlte eine vergleichsweise geringe Menge von Uran und eine entsprechende Menge von Schwerem Wasser, um den Versuch ganz so, wie man es gewünscht hatte, ablaufen zu lassen. Dieses restliche Material war in Haigerloch nicht mehr vorhanden, wohl aber in Stadtilm. Daher die Sorge Gerlachs um die Forschungsstätte Stadtilm. Nur dort war das Material, das den krönenden Abschluß der Bemühungen um eine kritische Uran-Maschine ermöglichen konnte.

It was probably the last day in March 1945 when Dr. Graue from the Kaiser Wilhelm Institute for Physical Chemistry and Electrochemistry appeared in my office early in the morning. “The uranium machine is running,” he reported excitedly and referred me to his boss, Prof. Thiessen, who had received a phone call from Gerlach the night before. I contacted my superior group leader, Dr. Spengler, and soon four of us sat together in Thiessen’s institute: Thiessen, Graue, Spengler and me. The telephone conversation Thiessen reported had apparently come about with great difficulty, the communication had been very poor. After all, two important messages resulted from Gerlach’s call. The first reported the great success with a critical uranium machine. The second message that Gerlach wanted to send me related to the threat to the research site in Stadtilm from the advance of the American troops to Thuringia.

From what I learned later, I must add that Gerlach’s overjoy at the successful attempt with a uranium machine was justified, but that his message had not been transmitted quite correctly. The critical uranium machine was not yet finished, but rather “nearly finished.” There was a comparatively small amount of uranium and a corresponding amount of heavy water missing to allow the experiment to run as desired. This remaining material was no longer available in Haigerloch, but in Stadtilm. Hence Gerlach’s concern about the Stadtilm research site. Only there was the material, which could make the crowning conclusion of the efforts possible around a critical uranium machine.

Commentary from Rainer Karlsch on the previous passage from Helmut Fischer [Jonastalverein Archive].

Rund zwanzig Jahre vor der zitierten Schilderung hatte Fischer den Verlauf der Ereignisse anders wiedergegeben: “Es musste schnell gehandelt werden. Denn der entscheidende Versuch mit der Uranmaschine war in Stadtilm erzielt worden.” [Diese Sätze hat Fischer später gestrichen. Vgl. Helmut J. Fischer, Feuerwehr für die Forschung, Institut für Zeitgeschichte München, Ms. 321/1-4]

Auch Fischers Vorgesetzter Spengler schrieb von einem funktionierenden Reaktor: “Im Anschluss an diese Sitzung [an 23. März fand im Harnack-Haus eine Sitzung mit Graue, Fischer, Schumann, Geist und Diebner statt—Dienstkalender Walther Gerlach, Deutsches Museum München] erzählten sie [Gerlach] mir, wie nahe die deutsche Atomkraftmaschine vor ihrem Abschluss stünde. Einige Wochen [Tage?] später berichtete Dr. Graue vom Erfolg, aber auch gleichzeitig von der drohenden Gefahr, dass die Forscher [in Stadtilm] vom Feind überrollt würden. Es war mir möglich, den Chef der Sicherheitspolizei zu bewegen, eine Autokolonne unter der Leitung des Oberführers Ehrlinger in Marsch zu setzen, und die Atomforscher, ihre Unterlagen und ihre Einrichtungen in Schutz zu bringen.” [Schreiben von Spengler an Gerlach vom 12. März 1948, Institut für Zeitgeschichte München]

Beide SD-Mitarbeiter sprachen nicht von Haigerloch, sondern von Stadtilm. Gerlach befand sich seit dem 30. März in Hechingen und sorgte sich um seine Leute in Stadtilm. Das dürfte der Hauptgrund für seinen hektischen Anruf am 31. März bei Thiessen gewesen sein. Thiessen verständige sofort den SD. Fischer und Spengler machten sich daraufhin auf den Weg zu Graue in der Kriegswirtschaftsstelle des Reichsforschungsrates. Unklar bleibt wo der SS-Reaktor gestanden haben soll.

About twenty years before the description quoted, Fischer had given a different account of the course of events: “We had to act quickly. For the decisive attempt with the uranium machine had been made in Stadtilm.” [Fischer later deleted these sentences. Cf. Helmut J. Fischer, Fire Department for Research, Institut für Zeitgeschichte Munich, Ms. 321/1-4]

Fischer’s superior Spengler also wrote of a functioning reactor: “Following this meeting [on 23 March a meeting with Graue, Fischer, Schumann, Geist and Diebner took place in the Harnack House—Dienstkalender Walther Gerlach, Deutsches Museum München] they [Gerlach] told me how close the German nuclear engine was to its conclusion. A few weeks [days?] later Dr. Graue reported about the success, but also about the threatening danger that the researchers [in Stadtilm] would be overrun by the enemy. It was possible for me to persuade the chief of the security police to march a motorcade under the leadership of Chief Ehrlinger and to protect the nuclear researchers, their documents and their facilities.” [Letter from Spengler to Gerlach dated 12 March 1948, Institut für Zeitgeschichte Munich]

Both SD employees did not talk about Haigerloch, but about Stadtilm. Gerlach had been in Hechingen since March 30 and cared for his people in Stadtilm. This must have been the main reason for his hectic call to Thiessen on March 31. Thiessen immediately informed the SD. Fischer and Spengler then made their way to Graue in the War Economic Office of the Reich Research Council. It remains unclear where the SS reactor is said to have been.

Edward M. Pickett to Assistant Chief of Staff, G-2, USFET. 4 March 1946. Subject: Additional Supply of Uranium Oxide. [NARA RG 77, Entry UD-22A, Box 169, Folder 32.32. Germ. Ind. TA] See document photo on p. 3871.

1. Reference is made to your letter from US Military Attaché, London, 14 December 1945, subject: "Materials in Laboratory of Dr. KIRCHENER, Garmisch", and letter your office same subject, dated 21 February 1946.

2. Additional quantities of Uranium Oxide have been located in the amount of approximately five and one-half tons at Bad Tölz and Munich. This material was found in the custody of Dr. Fritz REHBEIN, formerly part of the investigation group of the State Investigation Council (Reichsforschungsrat). It was inspected and left in his charge by Professor Charles P. SMYTH, Princeton University in June, 1945. Professor SMYTH also inspected the materials now located in Garmisch. This is the second occurrence in which like material was located in the custody of German scientific groups inspected by Professor SMYTH at which inspection he told the custodians to hold the material for further instructions. In view of this, request that Professor SMYTH be contacted to determine if other such material can be located or is in the custody of any other groups.

3. Dr. Fritz REHBEIN stated during investigation that the Uranium Oxide is very active and can be extremely injurious to personnel not qualified in its handling. [...]

Edgar P. Dean to W. R. Shuler. 1 April 1946. SUBJECT: Shipment of Uranium Compounds. [NARA RG 77, Entry UD-22A, Box 169, Folder 32.32. Germ. Ind. TA] See document photo on p. 3872.

1. Reference our cable 70400 of 28 March 1946. The following are the facts behind this shipment of uranium.

2. Early in the winter, we learned of the existence of $1\frac{1}{2}$ tons of uranium compounds at Garmisch-Partenkirchen. G-2 USFET was alerted to move the stuff. Actually, G-2 moved very slowly and we had to prod them on three successive occasions.

3. On the other hand, G-2 moved extremely quickly re the five tons of uranium oxide recently discovered at Bad Tölz. (See letter this office "Professor Smyth and Uranium Oxide in Germany", dated 15 March 1946.)

4. The two lots were consolidated into one at Bremerhaven and put aboard the Hagerstown Victory. This ship sailed on 19 March and should arrive in New York about 6 April.

[The U.S. hastily removed several tons of "very active" and "extremely injurious" uranium oxide that may have been irradiated in an operational fission reactor (perhaps Diebner's) and was associated with Fritz Rehbein (p. 4564) and C. P. Smyth (p. 4788). See also pp. 3473, 5077.]

HEADQUARTERS
THIRD UNITED STATES ARMY
Office of the Assistant Chief of Staff, G-2
APO 403

4 March 1946

Subject: Additional Supply of Uranium Oxide.

To: Assistant Chief of Staff, G-2, United States Forces
European Theater (Main), APO 757, US Army.

1. Reference is made to your letter from US Military Attache, London, 14 December 1945, subject: "Materials in Laboratory of Dr. KIRCHENER, Garmisch", and letter your office same subject, dated 21 February 1945.

2. Additional quantities of Uranium Oxide have been located in the amount of approximately five and one-half tons at Bad Tolz and Munich. This material was found in the custody of Dr. Fritz REHBEIN, formerly part of the investigation group of the State Investigation Council (Reichsforchungsrat). It was inspected and left in his charge by Professor Charles P. SYMTHE, Princeton University in June, 1945. Professor SYMTHE also inspected the materials now located in Garmisch. This is the second occurrence in which like material was located in the custody of German scientific groups inspected by Professor SYMTHE at which inspection he told the custodians to hold the material for further instructions. In view of this, request that Professor SYMTHE be contacted to determine if other such material can be located or is in the custody of any other groups.

3. Dr. Fritz REHBEIN stated during investigation that the Uranium Oxide is very active and can be extremely injurious to personnel not qualified in its handling. Thisis contrary to instructions for shipping material at Garmisch to the United States as given in paragraph 3 of your letter of 21 February 1946. By reason of such danger, request that specialist personnel be provided to prepare and supervise shipment. Routine of actual movement will be handled by G-4 Section, this headquarters.

4. Request authority to ship all material now located at one time.

EDWARD M. FICKETT
Colonel, GSC
AC of S, G-2

NOTE FOR THE FILES:

1. Dean in Frankfurt told Collins of G-2 USFET that uranium oxide is not injurious to personnel.

2. Collins to instruct Third Army and get them cracking.

3. Our instructions of 21 February to be complied with: material to be handled by USFET TC: shipped by surface transport from a German port to U.S. Army Engineer, 261 Fifth Avenue, N.Y.C., attn: Major W. E. Kelley; this office advised of sailing date and vessel's name; bill of lading to read special chemicals, non-explosive, non-inflammable,.and non-magnetic.

4. Symthe obviously is C. P. Smyth.

THIS DOCUMENT CONSISTS OF 1 PAGES
COPY NO. 3 OF 3 SERIES A

30 December 1946

Subject: Uranium Oxide at Posthof Eggmühle/Landshut.

To: Lt. Col. E. P. Dean, Office of the Military Attache, American Embassy, London, England.

1. Reference is made to your letter of 1 April 1946 entitled "Shipment of Uranium Compounds" and also your letter of 15 March 1946, subject, "Professor Smyth and Uranium Oxide in Germany" and particularly Inclosure No. 1 thereto.

2. A recent review of old documents on file in this office has brought to light the evidence of the attached memorandum, dated 22 May 1945, from Mr. C. A. Baumann, formerly of the ALSOS Mission, entitled "Uranium Oxide from Stadtilm".

3. It will be noted that this memorandum mentions that there were four separate towns or cities where uranium materials from Stadtilm were stored during an ALSOS operation:

1¼ tons Landshut – Arrived U.S. Apr. 47
Bad Tölz " " 5 Apr. 46
6½ tons Garmisch
Munich

4. It appears that all this material except that at Landshut has been shipped to this country after having been "rediscovered" by Third Army personnel. There are no references in our file, however, to show that the material at Landshut was ever removed and finally disposed of.

5. It is requested that appropriate investigation be conducted at Landshut to determine if the material is still there, or if not, its present location. If located, this material should be shipped to U. S. Engineer Office, 261 Fifth Avenue, New York, N. Y., Attention: Lt. Col. A. W. Oberbeck, with notification to this office by cable of sailing date and name of vessel.

DISCUSSED THIS W/ FURMAN TODAY.
He SAYS this stuff is "sludge" and
of not much value. A "case" is about
~~the size of~~ 12" x 12" x 18".
1-1-47
JEJ.
He does not think it was ever removed from Landshut

L. E. SEEMAN,
Colonel, Corps of Engineers.

4. A possible fission reactor in the Bergkristall tunnel complex in Austria

[Rudolf Haunschmied and Andreas Sulzer have gathered a huge amount of unpublished archival documents, witness statements, aerial photographs, and other evidence that strongly suggests that part of the Bergkristall tunnel complex at St. Georgen/Gusen near Linz, Austria was conducting nuclear-weapons-related work during the war. From some of the evidence, it sounds as if the complex may have even included an operational fission reactor and facilities for extracting bred plutonium-239 or uranium-233 from irradiated reactor fuel. German forces sealed the entrances and air shafts to that part of the tunnel complex shortly before the end of the war, and they have remained sealed for 75+ years. Air and water samples taken from the site in recent years have remarkably high levels of radioisotopes, which may or may not be due to purely natural causes.

Until all of the documentary evidence is available, and/or until the site can be properly excavated and analyzed, the true nature of this facility cannot be settled. A very small sample of the documentary evidence is presented below and on the following pages.

U.S. officials inspected this site and interrogated witnesses after the war; see pp. 4962–4970. Their reports on what they found and learned there have never been publicly released. Can those reports be located in archives and declassified?]

PW Intelligence Bulletin 2/50. 1 April 1945 [AFHRA folder 506.61952 Nos. 2/41–2/50 6 Mar–1 Apr 1945, IRIS 207533; AFHRA A5186 frames 0598–0599]

13. V-2 Factory, ST GEORGEN a/Gusen (Austria)

Preamble. Most of PW's information came from a girl who lives in ST GEORGEN. He met the girl while hospitalized in LINZ during Nov and Dec. 44. PW also saw the factory from the train while passing through ST GEORGEN en route to LINZ from FRESTADT.

Location and Layout. GSGS 4416/W9/974858. The entrance to the tunnel in which the factory is located is appr 3 m x 4 m. It is visible from the RR line appr 200 m away. A narrow-gauge RR leads to the site.

Production. PW's only indication that V-2s are manufactured at the factory is his informant's statement to the effect that because of an explosion in the factory in Sept 44 the commitment of the V-2 was delayed considerably. The explosion caused the death of 100 persons and the destruction of important machinery.

Personnel. Five large wooden barracks, located adjacent to the RR tracks, house an undetermined number of foreign workers. In addition, prisoners are brought in daily from the concentration camp in MAUTHAUSEN for work at the factory. Civilian workers are billeted in villages in the vicinity.

At the time of PW's departure in Dec 44 it was planned to keep workers inside the factory at all times, using artificial sunlight to keep them in good health. The plan was devised to eliminate the frequent breaches of security which had occurred.

Workers who lived in the barracks adjacent to the RR line were completely dissatisfied with living conditions. Once they even set fire to the barracks.

Flak. PW is not informed about Flat defenses.

PW INTELLIGENCE BULLETIN 2/50

12. Underground Factory, LOOSDORF (Austria) (continued)

Location. There is some disagreement among the 4 PWs as to the exact location of the installation, due perhaps to their having mistaken various entrances into the hillside for the central location. The different pinpoints they give, however, all fall within the area of the wooded hill S of the MELK-LOOSDORF RR line, between GSGS 4416/X10/653860 and 665848.

A single-track spur line leads from a small RR station at 668853 (not shown on the map sheet) to the factory site. A road 7 or 8 m wide runs from the LOOSDORF RR station to the site.

Construction. Work was begun in mid-summer 1944. One PW estimates that construction could have been completed by the end of the year. Another PW maintains that the MOOSBIERBAUM factory (see PW INTELLIGENCE BULLETIN 2/34 Item 14) was in the process of moving into the LOOSDORF installation.

Production. Two of the PWs do not know what was produced at the plant, but think it had something to do with chemicals, or possibly gasoline. PW D believes that Pressluft bombs were produced there, and PW C says that the plant works in close connection with the underground plant below the factory complex of Glanzstoff AG, ST POELTEN, and the WNF (Wiener Neustaedter Flugzeugwerke) in OBER-GRAFENDORF (GSGS 4416/X10/807793). The WNF, which is above-ground, produces jet-fighters and delivers them to the airfield at MARKERSDORF (760822) for testing.

The last time PW A passed by the LOOSDORF plant (Oct 44), he noticed on the RR track along the lower edge of the forest several tank cars bearing inscriptions such as "Chemische Treibstoffwerke MOOSBIERBAUM," "Sudetendeutsche Treibstoffwerke," etc. Some of the cars had the LEUNA Werke trademark. Trains standing on the spur line were made up of both tank and freight cars.

Personnel. The LOOSDORF plant's 20,000-25,000 workers consist of civilians (mostly Hungarians) and political prisoners. Workers are housed in barracks situated in the woods and on the plain between the woods and the RR station.

Security. The installation is heavily guarded by SS men, armed with automatic pistols, and GAF personnel. There are four high watchtowers 30 m from the main RR. PW C, whose father worked in the plant, tried several times to approach the installation, and once was almost arrested in the process. He never succeeded in reaching the premises, but from a distance he saw masses of prisoner-workers attired in black-and yellow-striped suits.

14. Bomb Damage, NUERNBERG

Preamble. PW A, a native of NUERNBERG, worked in the freight yards in that city until his induction in 1940. He was home on furlough from 18 Jan to 4 Feb 45. PW B is an Austrian whose wife lives in NUERNBERG. He was in the city from 5 to 25 Feb 45. Both PWs are well acquainted with NUERNBERG's industries and are of above-average intelligence.

General. In the raids of 1 Jan and 20 and 21 Feb 45 the industries and the main part of the city were practically destroyed. PW B heard from friends on the police force that appr 100,000 persons were thrown out of work as a result of bomb damage. Appr 60,000 of these were Germans, many of whom have since been drafted into the SS. PW B claims that the Army discontinued its draft in Feb 45, and that now all available manpower is forced into the Waffen SS. 37,000 were killed in the raids, many of them PWs and foreign workers.

MAN Works. The main works were completely destroyed in the 3 raids. MAN had ceased operations even before the raids, according to PW A, because of shortages in coal and raw materials. PW B heard from a Russian worker that the MAN tank works at Schlesingerstr and Frankenstr had been damaged but could be repaired quickly. The tank works received electricity from the SIEMENS-SCHUCKERT power plant - destroyed in the raids - and a delay of 3-5 weeks was expected until new power lines could be installed. This MAN plant produced 5 tanks daily prior to the attacks.

SIEMENS-SCHUCKERT. PW B heard that this power plant was damaged beyond repair. The firm's power distributor (Transmotorenwerk) was completely destroyed. PW B saw some machinery being salvaged.

Special Interrogation Report 2. 14 September 1944.

CAPTURED PERSONNEL AND MATERIAL BRANCH

Estimate of Veracity: Believed to be reliable. As a well educated man, Dr. Kornrumpf finds himself in strong opposition to the Nazis. Talks freely.

Civilian Background: Born 24 November 1909 in Fuerstenwalde, Spree, the son of a minister. He attended school through Gymnasium in this town, completing this phase of his education in 1929.

1929-30: University of Tuebingen; 1½ years.
1930-34: University of Munich; 8 semesters.
Fall 1933: Universities of Utrecht and Amsterdam. Here he worked in the Institute of Colonies.

He took his Ph.D. degree on 18 July 1934. His doctor's thesis was "Mensch und Landschaft auf Celebes". It was published by Teubner in 1934. He had planned to go into research work and therefore did not take any state examination which would have enabled him to become a teacher. His major field was geography; his minor, geology.

About the time he completed his doctor's work, he also planned to go to the Dutch East Indies for a time, but the growing economic autarchy of Germany prevented this. He was to go to Celebes Island and there work on a study of the climate. A section of this island had been deforested and then badly eroded, after which a type of cactus appeared and killed off all other vegetation. Reforestation was then commenced and carried on with good results. He intended to study the climate about 1933 when reforestation was still incomplete and then study it again ten years later for comparison.

Instead, he went to work for "Amt des Siedlungsbeauftragten", which is the German equivalent of our over-all regional planning board. This office or board seems to have been connected with both Rust and Kerrl, neither of whom was capable or interested enough to handle it right. A wealthy West German industrialist, Ludovici by name, owner of many brick kilns, was also connected with it and so was Hess. Ludovici is mentioned as being on Hess's staff. Incidentally, Ludovici is also mentioned in the recent book, "Axis Grand Strategy". Kornrumpf said Ludovici was soon fed up with the incompetence of the board's leadership and left it. Kornrumpf was eventually given an S.A. card by Hess to make things easier for him.

Upper Silesia, after the Polish Campaign, was an economic unit again and was greatly developed. Coal and iron are the base of Silesian industries but zinc and German's small nickel source are also here. Germany had planned a large-scale development of Upper Silesia by tying it in through canalization with the Vistula, improving the Vistula, and hooking this system up with the Danube through the March River. Some work has already been done on the March.

A great power and river control development was planned for Sandomir. The designs were prepared by the Technische Hochschule in Danzig. At Sandomir, there is a narrow gap for the Vistula which was at one time the outlet of a large lake. The dam would restore this lake and would have given sufficient water reserves to control the whole Vistula. The Poles had done little with the Vistula, had neglected it, and had preferred to ship Silesian coal by the French-built railway running north from there to Gdynia to the cheaper water transport down the Vistula to Danzig. Plans were under way in 1940. Kornrumpf knows no more about them. The upper Oder Valley has been developed a great deal.

In the south of Germany, the surplus population has concentrated largely in Wuertemberg where the Germans have concentrated their precision industries (Apparatebau). Baden belongs to this area, on the whole.

There is a small independent industrial area around Mannheim, Ludwigshafen, and over to Darmstadt which has developed a good chemical industry. Level area.

→ Linz's Hermann Goering Works, which were in production, were pretty well bombed out, according to what Kornrumpf heard.

Figure D.392: Captured Personnel and Material Branch. 14 September 1944. Special Interrogation Report 2 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-2 GERMANY: US Wartime Positive Int. (July–Oct. 44)]. "Linz's Hermann Goering Works, which were in production, were pretty well bombed out." Note that this report was of particular interest to Leslie Groves's Foreign Intelligence Unit.

[Note that the sources of these trains appear to be linked to the nuclear program:

- Witkowitz/Vitkovice was part of the city of Maehrisch-Ostrau/Ostrava, mentioned in the "Azusa" (nuclear) document on p. 3748 as having one of at least two I.G. Farben factories that were using "30,000 employees" to produce "the component of a new explosive" that was of great interest to U.S. intelligence. See also p. 3784.

- Ohrdruf was alleged to have underground facilities for nuclear-related work and is where a nuclear weapon was apparently tested (pp. 4436 ff., 4478 ff.).

- Belgium is where the uranium refineries and storage facilities of Union Minière du Haut Katanga were located [Irving 1967, p. 65]. After being controlled by Germany for over four years, they were captured by Allied forces in early September 1944 (p. 3324), just a couple of weeks after that train left on 23 August.

- Oranienburg was the home of both Auergesellschaft, which processed uranium and thorium ore [Irving 1967; Nagel 2016], and an even more mysterious SS facility that appears to have been involved with nuclear weapons development (pp. 4180, 4182).

- Salzgitter was the primary location of the Reichswerke Hermann Göring, a massive government-run metallurgical company for refining and casting iron and other metals of military importance (in this case perhaps uranium or plutonium, or other metal parts for nuclear bombs or reactors?).

- Auschwitz apparently had a heavy water production facility (p. 4452) and was said to be linked to the production and testing of atomic bombs (p. 4463).

Also note that the recipients of these trains appear to be related to the nuclear program [Haunschmied et al. 2007; Haunschmied in Joseph Fisher 2017, pp. 175–240]:

- DEST (Deutsche Erd- und Steinwerke GmbH) was an SS-run company originally founded in 1938 to exploit concentration camp labor in granite quarries like Gusen or Mauthausen and belonged to the SS-WVHA from March 1942. Its regional headquarters for the Mauthausen-Gusen complex were located at St. Georgen/Gusen since 1940. In 1943 the St. Georgen branch of DEST became a key contractor for companies like Steyr-Daimler-Puch AG and Messerschmitt GmbH in order to safeguard the production of advanced weapons in huge factories in Gusen and St. Georgen above ground as well as underground. Even SS quarries at Beneschau [Benesov] in Bohemia were controlled by the St. Georgen branch of DEST during the period 1943–1945.

- Karl Fiebinger was the chief engineer of many massive underground facilities for advanced weapons production in the Third Reich.

- Hans Kammler was the SS general who controlled virtually all of the advanced weapons programs, including the nuclear program, by the end of the war.

- SS-WVHA (SS-Wirtschafts- und Verwaltungshauptamt) was the SS Main Economic and Administrative Office, which provided huge amounts of funding and political support for SS-run weapons programs and production facilities.

- SS-Obersturmführer Werner Eckermann was chief of the SS-Führungsstab (leadership staff) "B8" for the construction and operation of the "Bergkristall" underground plant at St. Georgen/Gusen. He was Kammler's representative for his St. Georgen operations and reported to Kammler's SS-Sonderinspektion IV. In the period between October 1943 and June 1944 he was also responsible for Kammler's operation "Schlier" at Redl-Zipf, Austria.

- Siegfried Flügge was one of the very first nuclear physicists to propose how fission reactions could be used to create reactors and bombs (p. 3366), and he was a leading figure in the German nuclear weapons program from its beginnings in 1939 until the end of the war (pp. 3376, 3608, 4996–4992).

- Böhm is listed immediately alongside Siegfried Flügge as a recipient for important components. A Technical Sergeant Böhm was in charge of coordinating engineering tasks and deliveries at Gusen.

- KZL (Konzentrationslager) was the general designation for a concentration camp, in this case the Gusen concentration camp and production facility.

After the war, the United States gained detailed knowledge from most of these places and people, yet has never released reports on what it learned:

- The Belgian facilities of Union Minière du Haut Katanga were captured by U.S. forces in September 1944 (p. 3324).

- The Salzgitter headquarters of the Reichswerke Hermann Göring was captured by U.S. forces in April 1945.

- The Ohrdruf area was captured by U.S. forces in early April 1945 (pp. 4566–4570). Other than photos of concentration camp inmates, details of what the United States learned from the underground installations and from interrogations of personnel have never been publicly released. In order to succeed with the construction task at Ohrdruf, Karl Fiebinger sent his best on-site planning manager at the end of 1944 directly from St. Georgen an der Gusen (Bergkristall) to Ohrdruf [Rudolf Haunschmied, in Joseph Fisher 2017, pp. 175–240] .

- Gusen itself was captured by U.S. forces in early May 1945 (p. 4962 ff.). As with Ohrdruf, other than a few photos, details of what was learned from the underground installations and from interrogations of personnel have never been released [Haunschmied et al. 2007; Haunschmied in Joseph Fisher 2017, pp. 175–240].

- The United States received intelligence on nuclear-related work at Auschwitz (p. 4452), the Ohrdruf/Arnstadt/Crawinkel area (pp. 4566, 4570), Oranienburg (p. 3334), and Witkowitz (p. 3748).

- Karl Fiebinger worked in the United States for many years after the war as a "consultant" on secretive government projects (pp. 4986–4991, 4993). His accomplishments in the United States apparently included designing underground missile silos for intercontinental ballistic missiles, which may shed light on the true nature and extent of his wartime work for Germany [Freund and Perz 1987, p. 44].

- Siegfried Flügge worked in the United States after the war at the extremely specific and highly unusual invitation of Edward Teller, the leading physicist in the postwar U.S. nuclear weapons program (p. 4996).

- Hans Kammler was captured by the United States and interrogated for many months or perhaps even years after the war (pp. 4931–4959).

Walter Chmielewski, the son of Karl Chmielewski, the former Commandant of the Gusen concentration camp. 2016 filmed interview with Andreas Sulzer [Sulzer and Brauburger 2019a, 2019b].

Es war nur die Rede von insgesamt (sollen es) 30–40 Kilometer sein was da an Stollen angelegt worden sind und zum Teil eben auf zwei Ebenen. Also das kam durch bei Gesprächen mit SS-Leuten und dort findet jetzt Atomforschung statt. Mit Hochdampf geforscht werden soll, das noch zur Rettung der Nation, so ungefähr, die Atombombe fertig werden könnte, damit da noch einmal agiert werden kann, Ja. Das war eindeutig bei Gusen im Gespräch, dass diese Forschungen bereits stattfinden.	There was the precise talk of a total (of about) 30–40 kilometers of tunnels which have been created and partly in fact on two levels. This came through in talks with SS people and there is now nuclear research being carried out there. Under high pressure there is research, which could still save the nation, so to speak; the atomic bomb could be constructed, so that the initiative can be recovered again, yes. This was clearly stated at conversations in Gusen, that this research is already taking place.

[In Chmielewski's complete interview, he stated that:

- There was a huge underground concentration camp between St. Georgen and Langenstein.

- By mid-1944 a direct order from Hitler was received to accelerate the work on the atomic bomb (at any cost in material or human life) at St. Georgen and slow down the efforts on the Me-262 jet, given that only the first weapon was "war decisive" ("kriegsentscheidend").]

OPERATIONAL PRIORITY

From: US Military Attache, London, England

To: War Department

No: 43781 21 May 1945

Signed Van Voorst to MILID serial number 43781 TOP SECRET LOCO personal from Calvert to Groves for Smith.

1. Following taken from story on front page London Daily Express, Monday, 21 May.

"Secret Army fought Nazi Atom Bomb. It can be revealed today that for 5 years British and German scientists fought their own war - within-a-war. They fought to perfect the Atom Bomb, which, with the most explosive force in the world, would have given either side walk-over superiority.

"But it was no war of theorists only British and Norwegian paratroops fought it out too with Wehrmacht men and their Quisling supporters in the white hell of the storm-swept Hardanger Plateau in Norway.

"The Germans opened the fight in the summer of 1940. A few weeks after moving into Norway they seized the vast Hydro-Electrical Works at Rjukan. These works fed by the famous "Smoking Cascade" waterfall, supply electricity plentifully. And plentiful electrictiy was essential to the German plan and to the arms plant they intended to set up at Rjukan.

"Their plan was to: - Split the Atom. At Rjukan the Norwegians produced large quantities of a substance known as "Heavy water". Heavy water contains atoms of hydrogen twice as heavy as those contained in ordinary water, from which it can be made electrically. The price of heavy water is about 1500 pounds to 2000 pounds a pound.

From: US Military Attache, London, England

No: 43781 21 May 1945

"Scientist the world over had experimented with heavy water and they believed that if they treated the metal uranium with it under great force they could split the atom of uranium. And in doing that they would release terrific energy -- and produce a catastrophic explosion.

"There are many technical difficulties but the Germans may have been near solving them. All they needed was sufficient heavy water to go ahead with their experiments. And with Rjukan in their hands they were ready to go ahead.

"The manager of the works was called to Berlin. There he was questioned by Speer Arms Chief and by scientists from the Wehrmacht laboratories. He told them as much as he had to -- he was a Patriot.

"Then, back in Norway, he told his friends what the German plans were. By this time the Germans had the plant heavily enough guarded to rule out sabotage -- but no German capable of understanding them had yet seen the research records at Rjukan. Lief Tronstad, Professor of Chemistry, Patroit of Norway, burned them all.

"Then with the scientists who had worked with him, Tronstad fled to Britain. In a little Scottish town he resumed his experiments. Army, Navy, and RAF experts and members of the Committee for Scientific Warfare worked with him. The race to produce the atom bomb was on.

"In November 1942 the race turned into war. 25 British specialists were chosen to go to Rjukan on the Hardanger Plateau. Their job -- sabotage.

CM-IN-19865 (21 May 45)

TOP SECRET

"They were going to wreck the laboratories and destroy if they could all the heavy water the Germans had made. The Germans brought in new plant. By April 1944 they had made 12 tons of heavy water and were going to ship it over Lake Tinsjoe and into Austria where the first atom bombs would be made."

2. The rest of the story deals with the adventures of the saboteurs.

3. Story datelined Oslo, Sunday written by E. D. Masterman. Make White says stories originating in other countries not subject to British censorship and therefore this story no violation. This interpretation of code new to me leaves way open for complete security breakdown. Unable to contact any of our British Counterpart today as a holiday.

Figure D.396: Map of the Gusen concentration camps and the Bergkristall and Kellerbau tunnel complexes [AFHRA, courtesy of Rudolf Haunschmied].

Key for Fig. D.396:

(1) Mariengrube or Mögle-Grube (central access to individual tunnels of Bergkristall).

(2) Main entrance to Bergkristall (former Huemer sand pit near Saurüsselberg).

(3) Boiler and bath house for Bergkristall civilians.

(4) St. Georgen/Gusen railway station and start of the SS Schleppbahn to Gusen I and Gusen II camps.

(5) Dump for sand excavated by inmates during tunnel construction; called "Kippe."

(6) Bergkristall wastewater treatment plant, which was built for approximately 10,000 people.

(7) Home of DEST apprentices and first office of Karl Fiebinger's construction company at St. Georgen.

(8) Ventilation tower of Bergkristall at the Karlinger house.

(9) Chain of Bergkristall sentry posts with watchtowers.

(10) DEST garages at the Rapata house (later tank garages for the Soviet occupation force).

(11) Second settlement of DEST in St. Georgen, called "Deutsche Erd- und Stein Siedlung."

(12) Air-raid shelter of the DEST leadership at St. Georgen (outpost of the WVHA).

(13) Gusen I camp roll call area with prisoner kitchen and brick prisoner blocks.

(14) Not shown.

(15) Main entrance to Gusen I camp (so-called "Jourhaus"). In front are the barracks of the SS guards for Gusen.

(16) Coal bunker, depot, blacksmith's shop, and farm yard.

(17) Messerschmitt production halls (from 1943 onward, production of fuselages and wings for the Me 109).

(18) Sewage treatment plant for Gusen I camp and production halls I-V for Steyr-Daimler-Puch AG.

(19) Gusen II camp (housing for prisoners for Bergkristall construction and production).

(20) Kastenhof-Oberbruch quarry and guard chain.

(21) Kastenhof quarry with huge gravel crusher and terminal station of SS Schleppbahn at Gusen I.

(22) Chain of guards.

(23) High water tank for KL Gusen II.

(24) Chain of items.

(25) Pierbauer quarry. A separate field railway track also went up to this quarry.

(26) Gusen quarry.

(27) Unidentified.

(28) Gusen gravel pit.

(29) Deep vertical shaft where there may be an underground concentration camp [see pp. 3898–3899].

(30) Housing barracks I-IV for harbor construction.

(31) Kellerbau underground plant where production facilities of Messerschmitt GmbH, Steyr-Daimler-Puch AG, and Waffentechnische Lehranstalt der Waffen-SS Graz were located.

(53) Gravel crusher and loading site for Danube gravel to make concrete for Bergkristall. A separate railway connected the Danube bank with the concrete mixer at the Bergkristall construction site.

Figure D.399: Enlargement of the upper left of U.S. aerial surveillance photo of the area including the Bergkristall tunnel complex at St. Georgen/Gusen, taken on 2 April 1945. Note the two labelled "new pipelines" that were apparently bringing water to and from the tunnels that may have been involved in nuclear work. At the left end of the upper pipeline "(i)" is a mysterious octagonal structure that was filled in by German forces before the arrival of the U.S. military [AFHRA Report U 57 on St. Georgen, courtesy of Rudolf Haunschmied].

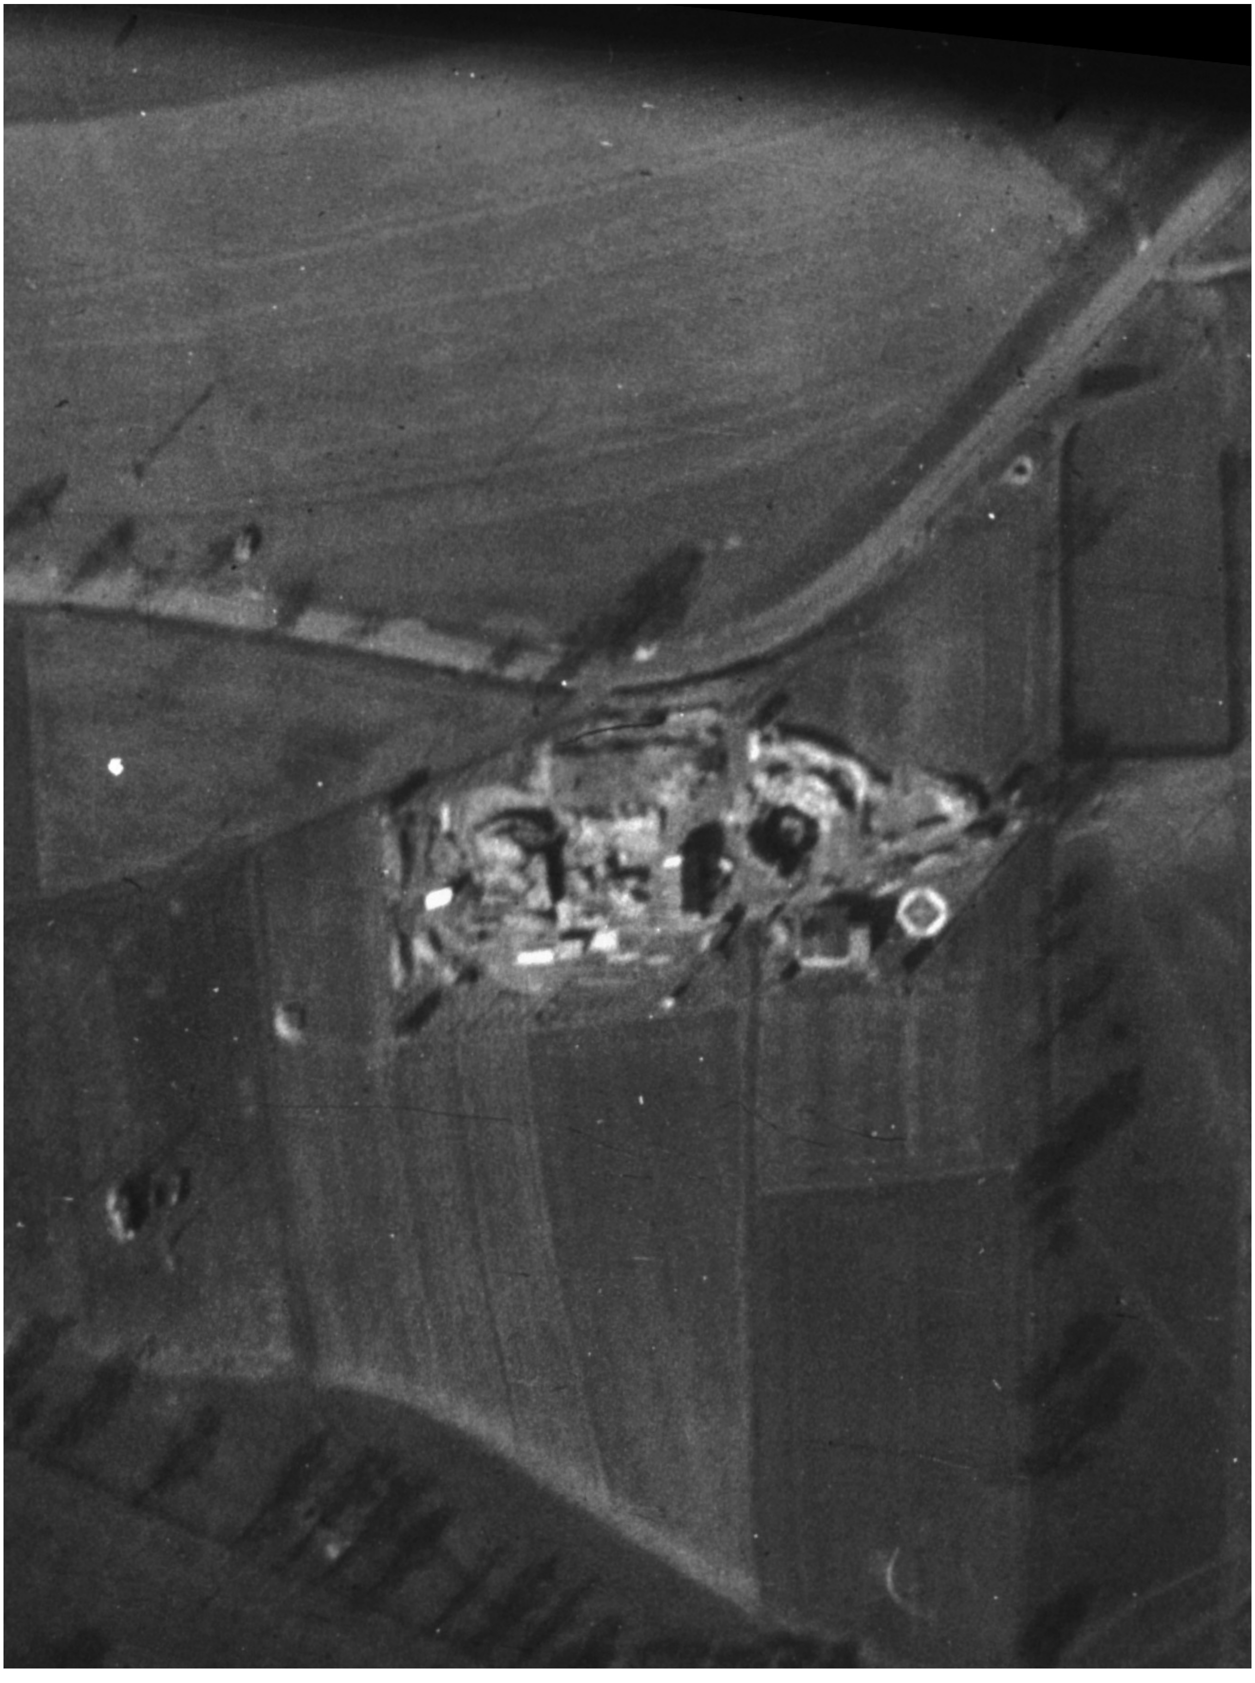

Figure D.400: U.S. aerial surveillance photo of the area directly northwest of the known Bergkristall tunnels, taken on 15 March 1945. Just to the right of the center of the photo is a large octagonal structure with very thick walls. The center of the octagon is open and appears to be rather deep in the ground. Also note other nearby structures and air vents. These structures do not appear on any surviving maps of the Bergkristall tunnels [AFHRA, courtesy of Gunther Hebestreit].

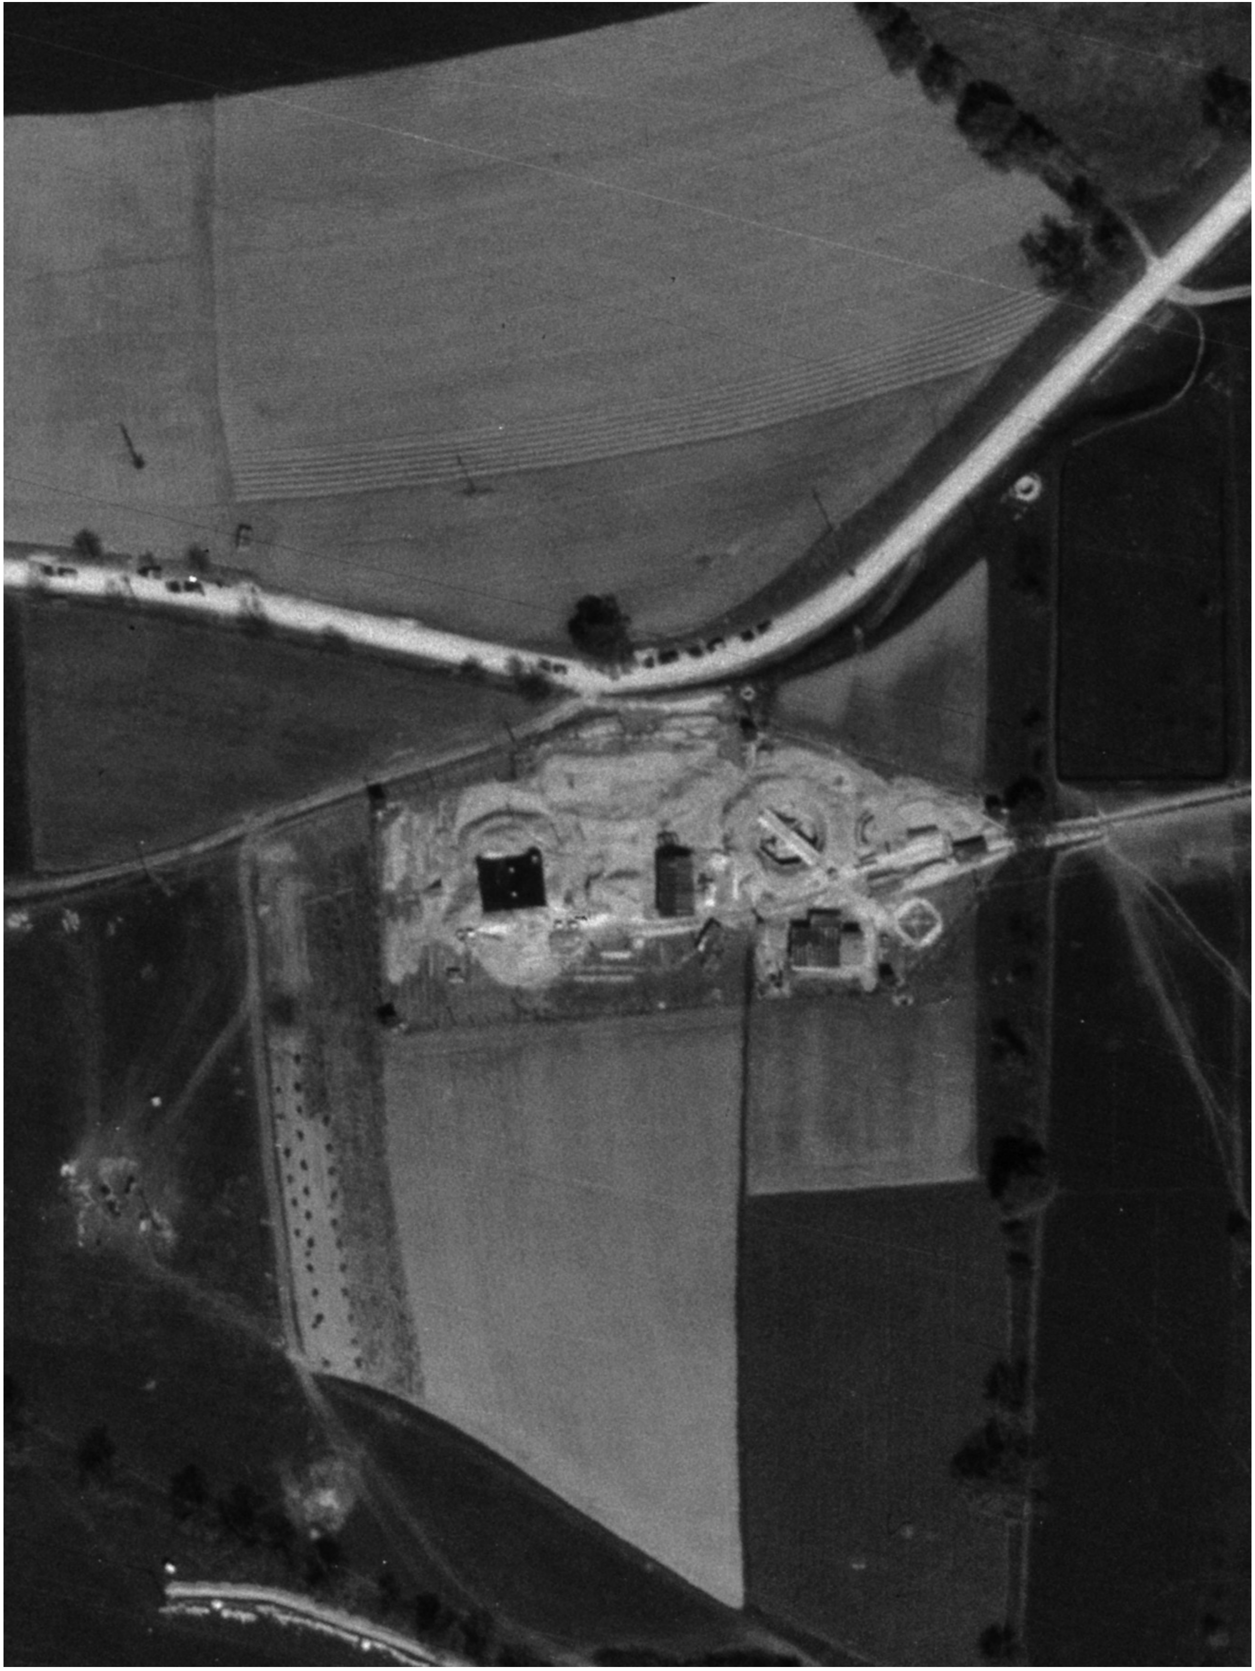

Figure D.401: U.S. aerial surveillance photo of the area directly northwest of the known Bergkristall tunnels, taken on 16 April 1945. The octagon and adjacent structures have been filled in with fresh dirt, indicating that this part of the underground installation has been sealed by German forces before the arrival of the U.S. military [AFHRA, courtesy of Gunther Hebestreit].

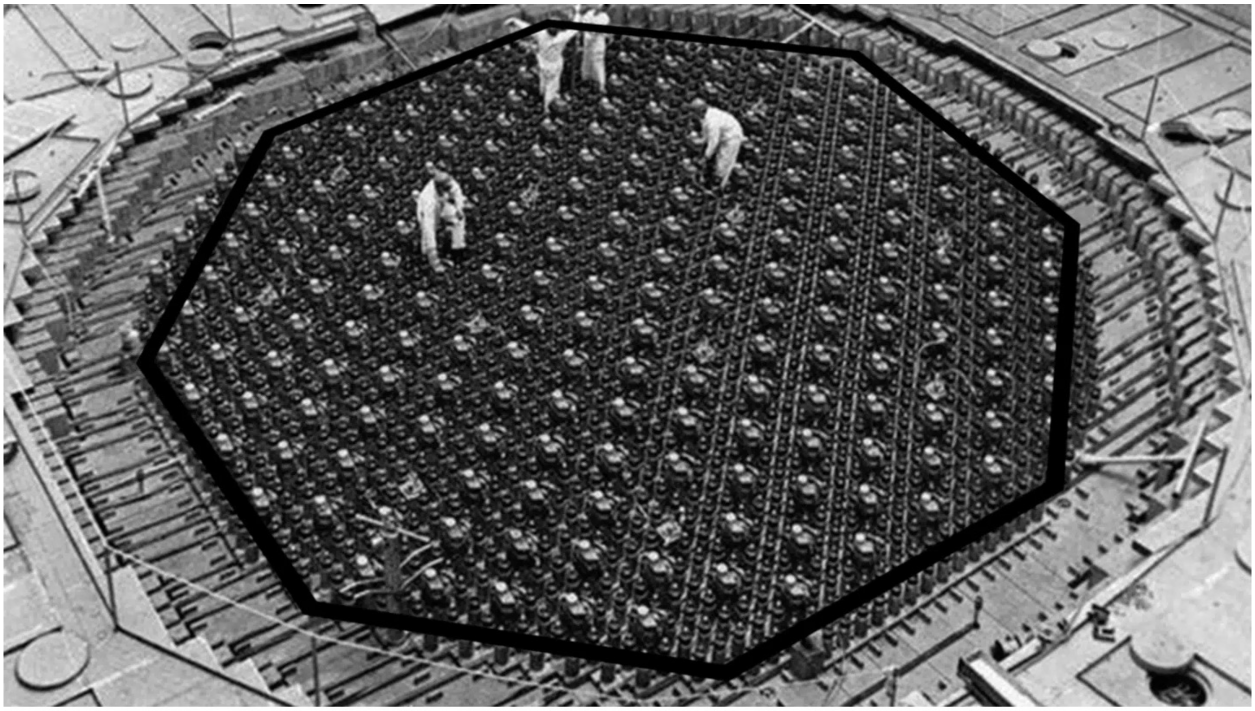
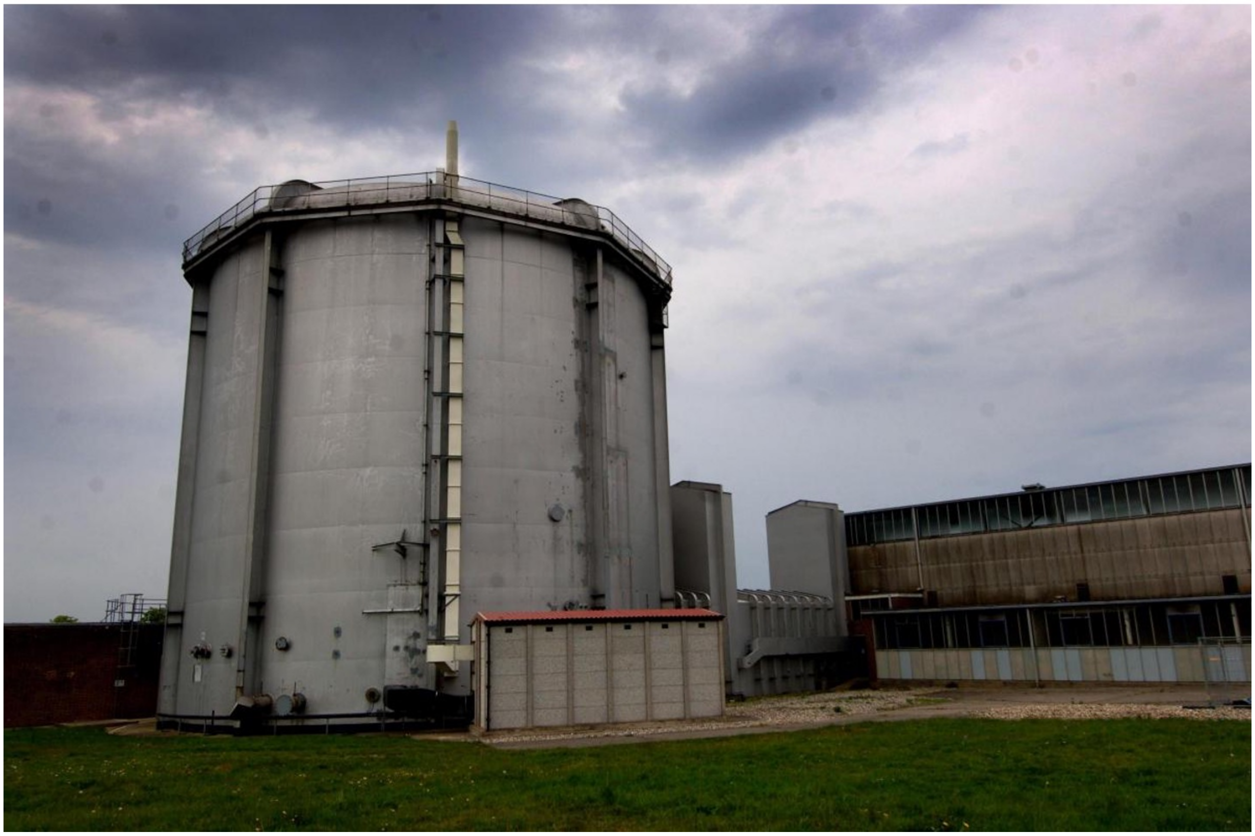
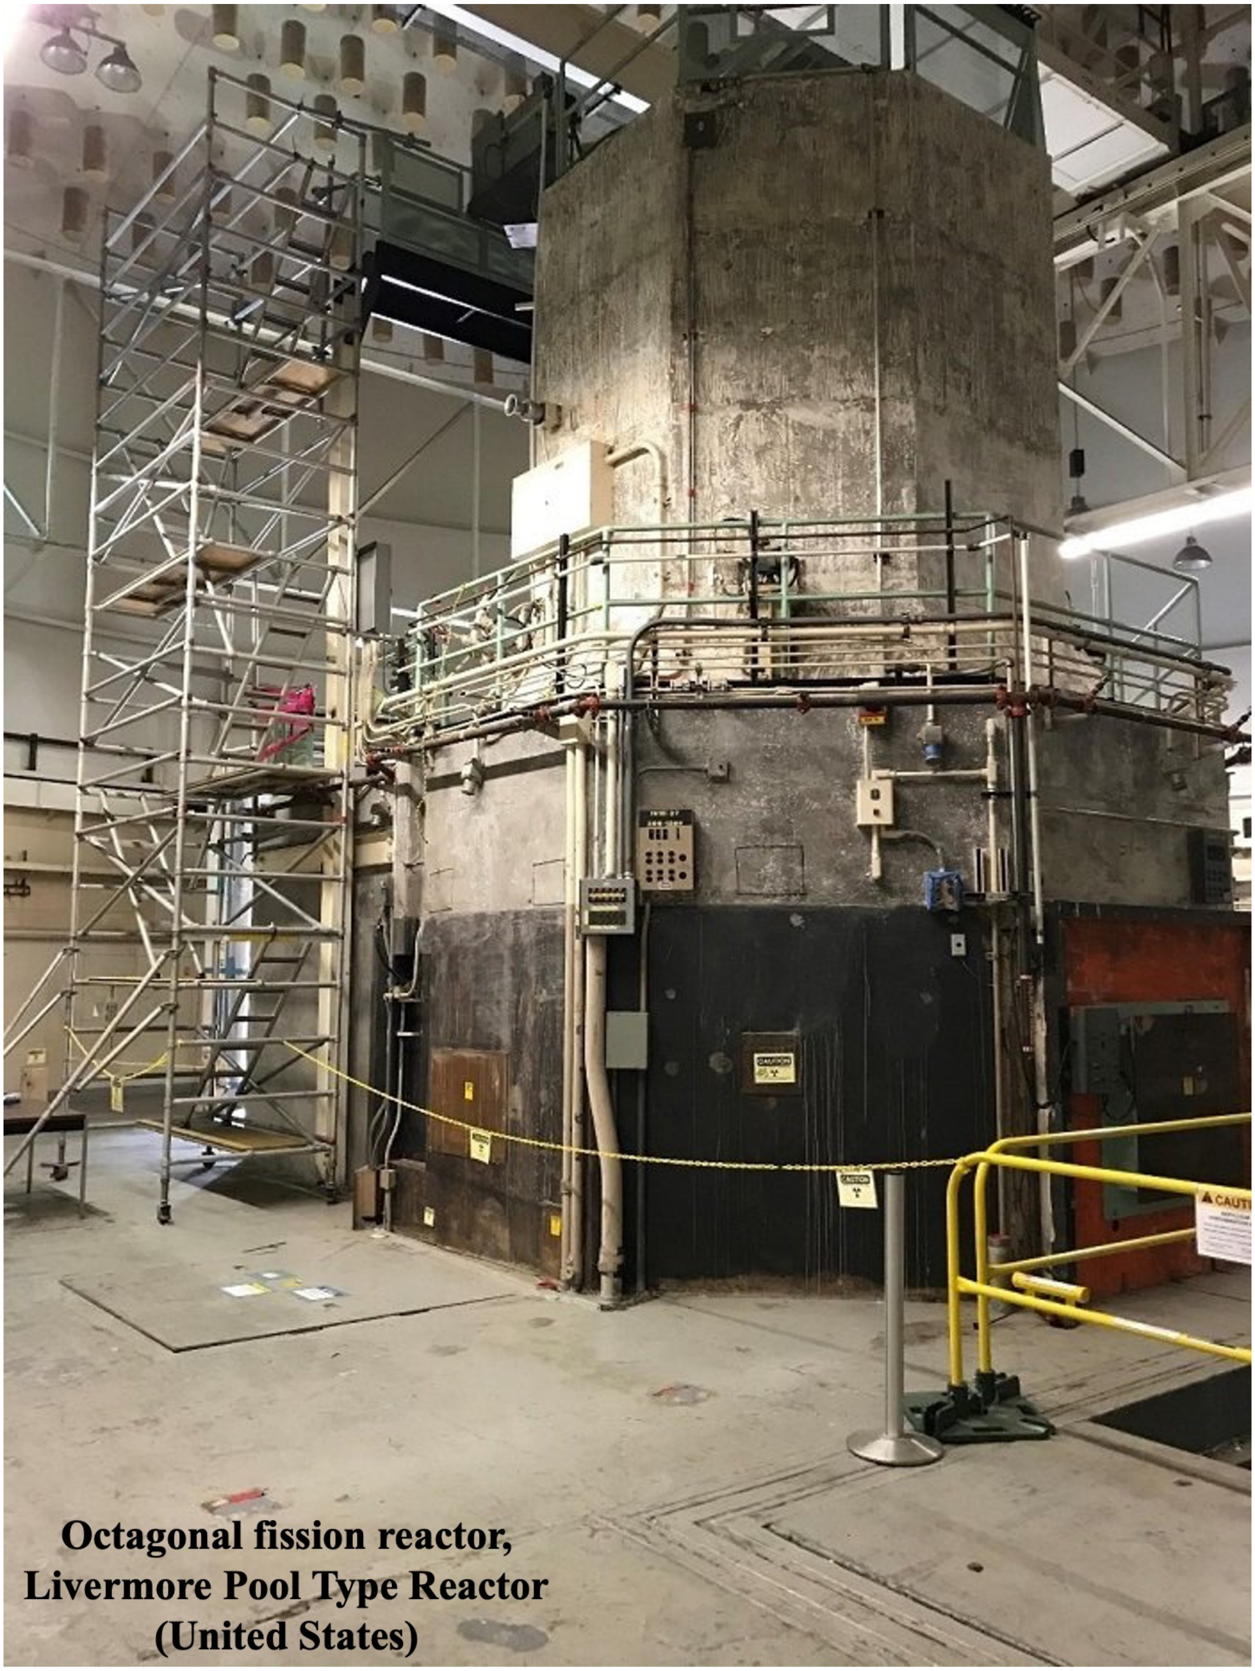


Octagonal fission reactor, Chernobyl RBMK (Ukraine)



Octagonal fission reactor, Harwell PLUTO (United Kingdom)

Figure D.402: Examples of octagonal fission reactors that were built in other countries after World War II. Compare with the images on pp. 3894–3895 and 3906.



Octagonal fission reactor,
Livermore Pool Type Reactor
(United States)

Figure D.403: Examples of octagonal fission reactors that were built in other countries after World War II. Compare with the images on pp. 3894–3895 and 3906.

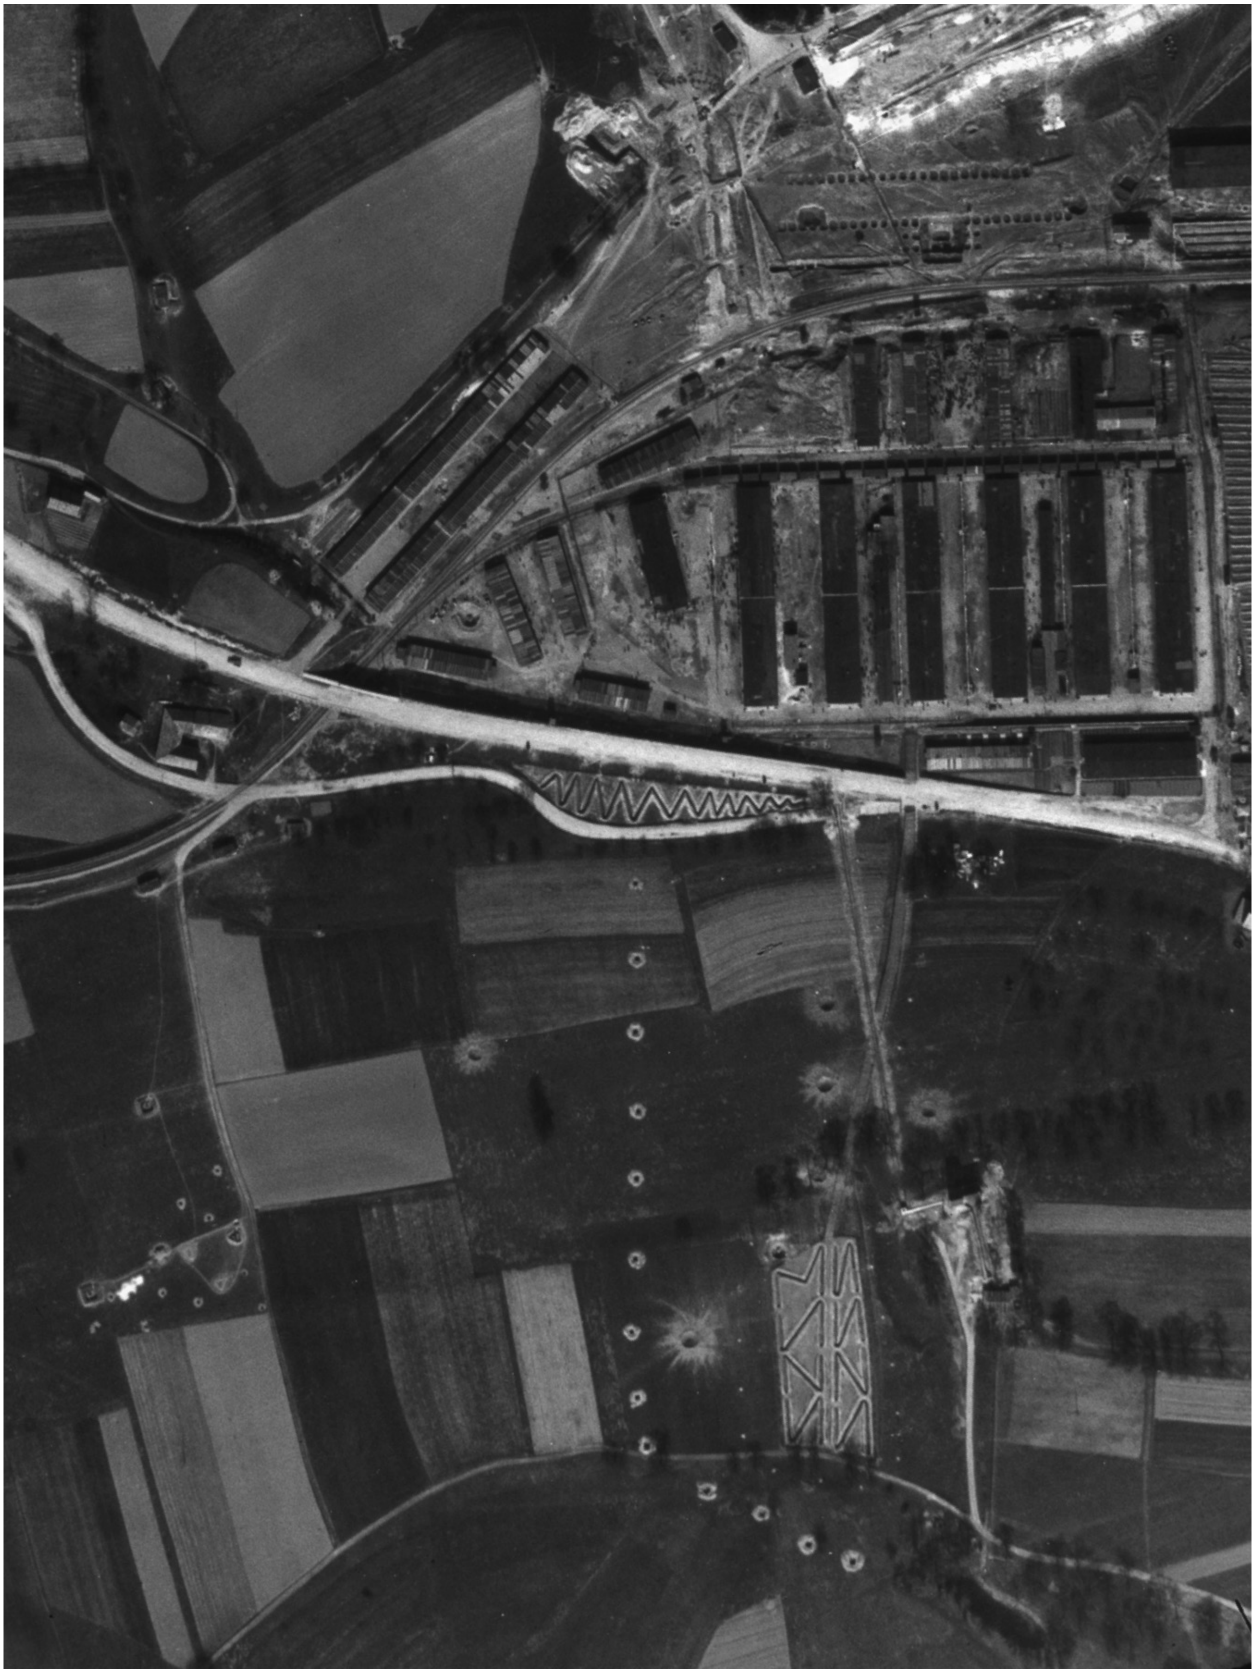


Figure D.404: U.S. aerial surveillance photo of the area directly south of the Gusen II camp, approximately 1.5 km southeast of the Bergkristall tunnel complex, taken on 2 April 1945. In the lower half of the photo, note all of the open air vents to a very large underground installation. This underground installation does not appear on any surviving maps of tunnels in the area. Zigzag patterns were air-raid trenches that were filled with prisoners as human shields against Allied bombing, suggesting great military value for the installation [AFHRA, courtesy of Gunther Hebestreit].

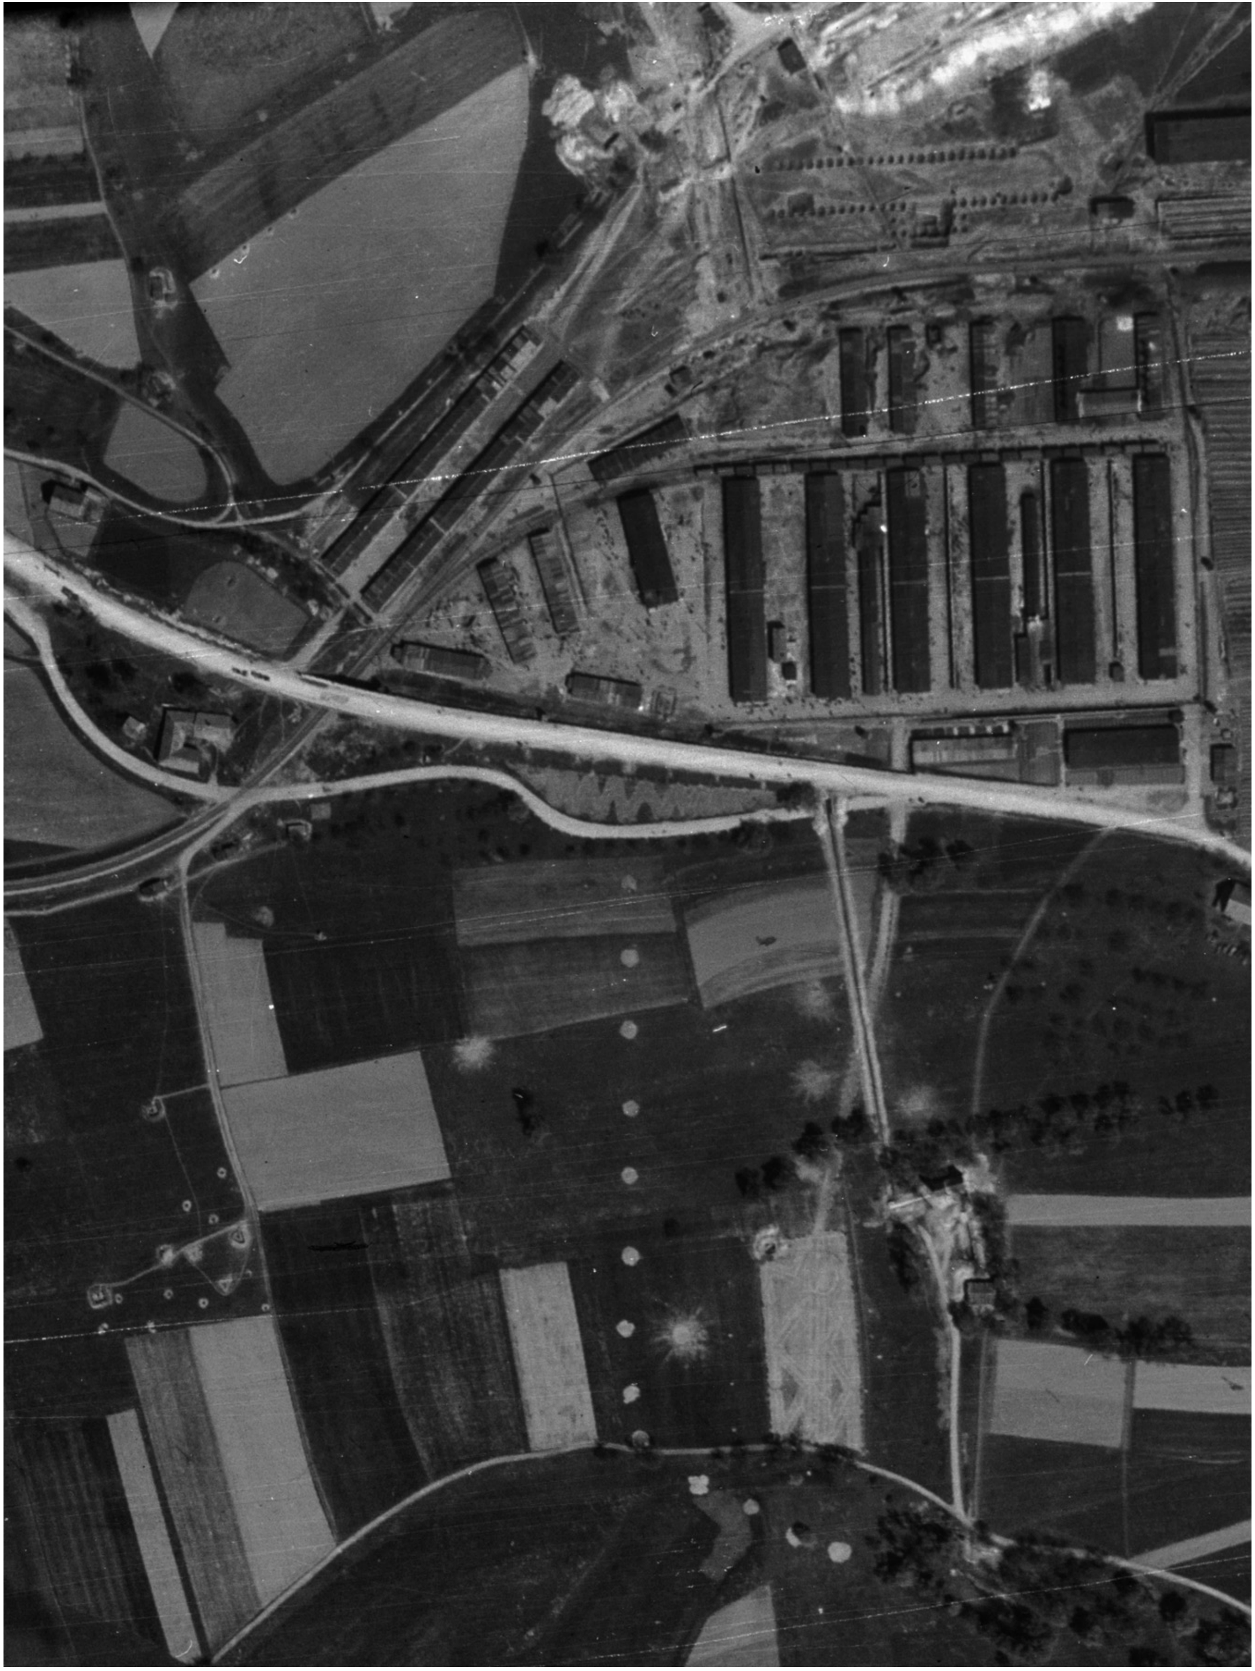

Figure D.405: U.S. aerial surveillance photo of the area directly south of the Gusen II camp, approximately 1.5 km southeast of the Bergkristall tunnel complex, taken on 16 April 1945. In the lower half of the photo, note that almost all of the air vents have been filled in, indicating that the underground installation has been sealed by German forces before the arrival of the U.S. military [AFHRA, courtesy of Gunther Hebestreit].

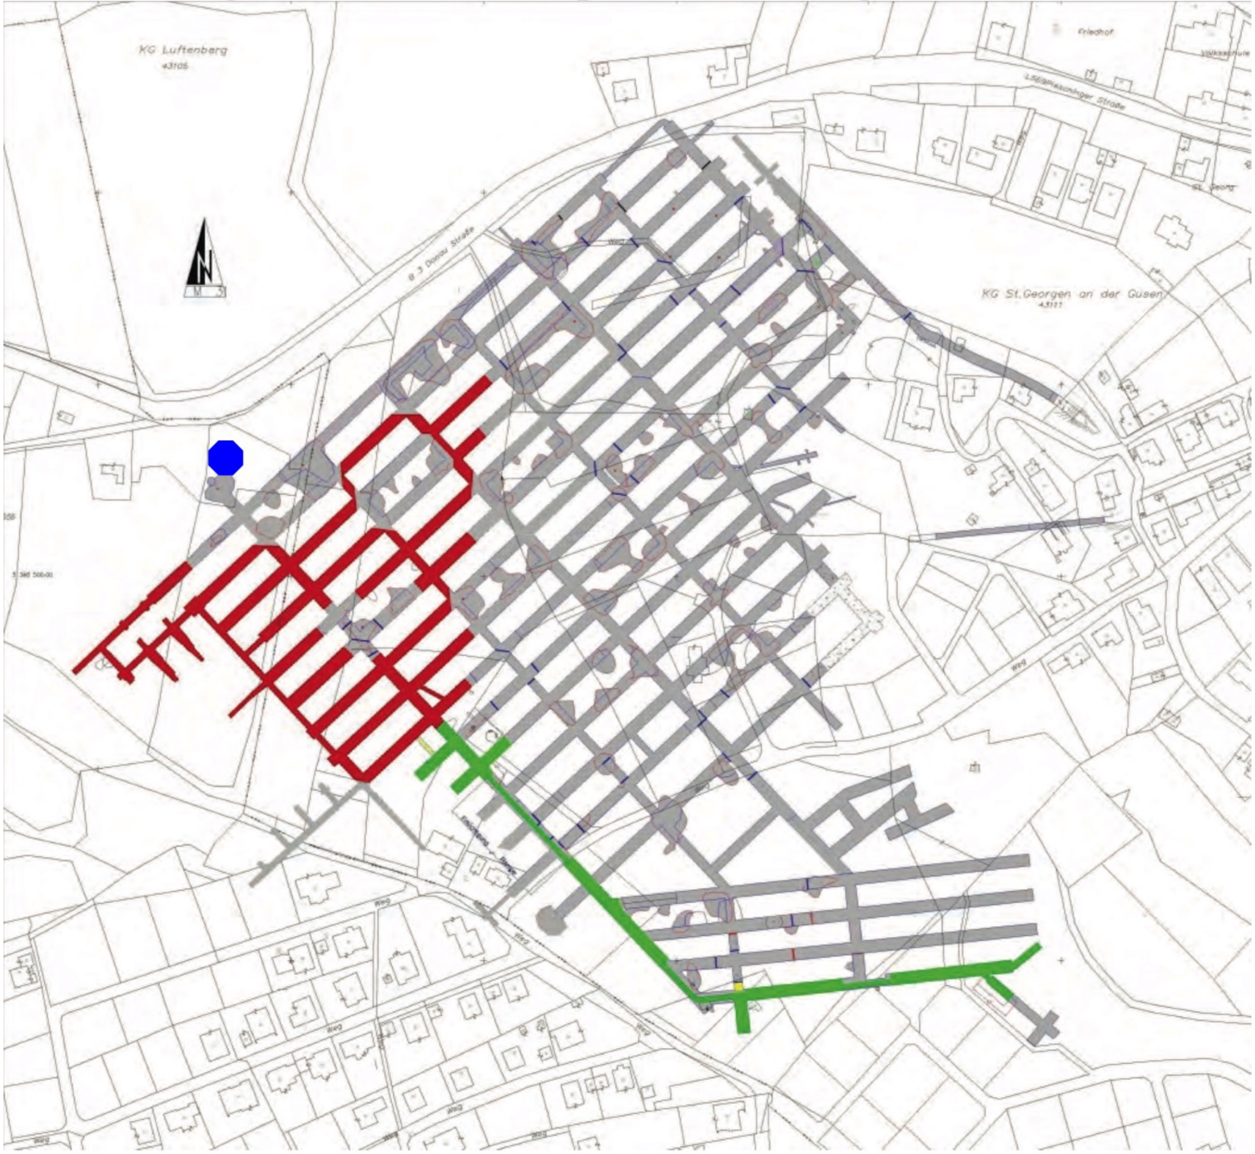
B8 Bergkristall tunnel complex at St. Georgen an der Gusen



Green: Accessible to the public twice per year

Red: Not accessible to the public

Gray: Filled with concrete by Austrian government 2002–2009

Blue: Octagonal structure visible in 1945 aerial photos but not shown in any surviving tunnel maps

7 kilometers total of tunnels are shown on this map. However, up to 19 kilometers of additional tunnels were sealed by the Third Reich shortly before the end of the war and are not shown on this map.

Figure D.406: Map of 7 kilometers of the Bergkristall tunnel complex now. Up to 19 kilometers of additional tunnels were sealed by the Third Reich shortly before the end of the war and are not shown on this map. The blue octagonal structure appears in 1945 aerial photos but not in any surviving tunnel maps.

Sammlung Franz Jakob [courtesy of Andreas Sulzer].

[?? Jakob (18??–19??) was an Austrian engineer who was involved in the construction of the Bergkristall underground tunnels up to 1945. From 1945 to 1955, occupying Allied forces exerted control over Austria in general and the tunnels in particular. When Austria regained full independence in 1955, Jakob promptly proposed to the Austrian government that they should create fission reactors, and that the reactors should be located in the Bergkristall tunnels. His proposal explained that the wartime tunnels were already ideally suited for fission reactors, conveniently omitting any explanation of why the tunnels just happened to have been designed that way. His proposal also explained that many of the experts involved in designing and building the tunnels during the war were still available to help establish operational fission reactors there.

Jakob's 1944 photos of Bergkristall clearly show that there were multiple levels of tunnels, not just a single level as the Austrian government has claimed. Multiple levels would also make the total length of the tunnels far longer than the officially recognized size. See especially pp. 3902–3903.

Jakob's 1955 proposal and accompanying notes included sketches of two fission reactors (Atom-Meiler) he wanted to make operational in the Bergkristall tunnels; see pp. 3906–3907. They look remarkably like the two octagonal structures protruding from the Bergkristall tunnels in the March–April 1945 aerial photos (pp. 3894–3895).

Jakob's 1955 proposal also mentioned how extensively the underground facility had been stripped by occupying forces after the war, first by the United States and then by the Soviet Union. Where are all the archival reports on everything that was found and removed by Allied forces?

Many of Jakob's wartime photos of Bergkristall and his 1955 proposal and notes were preserved by his son Franz Jakob and later presented to Andreas Sulzer.]

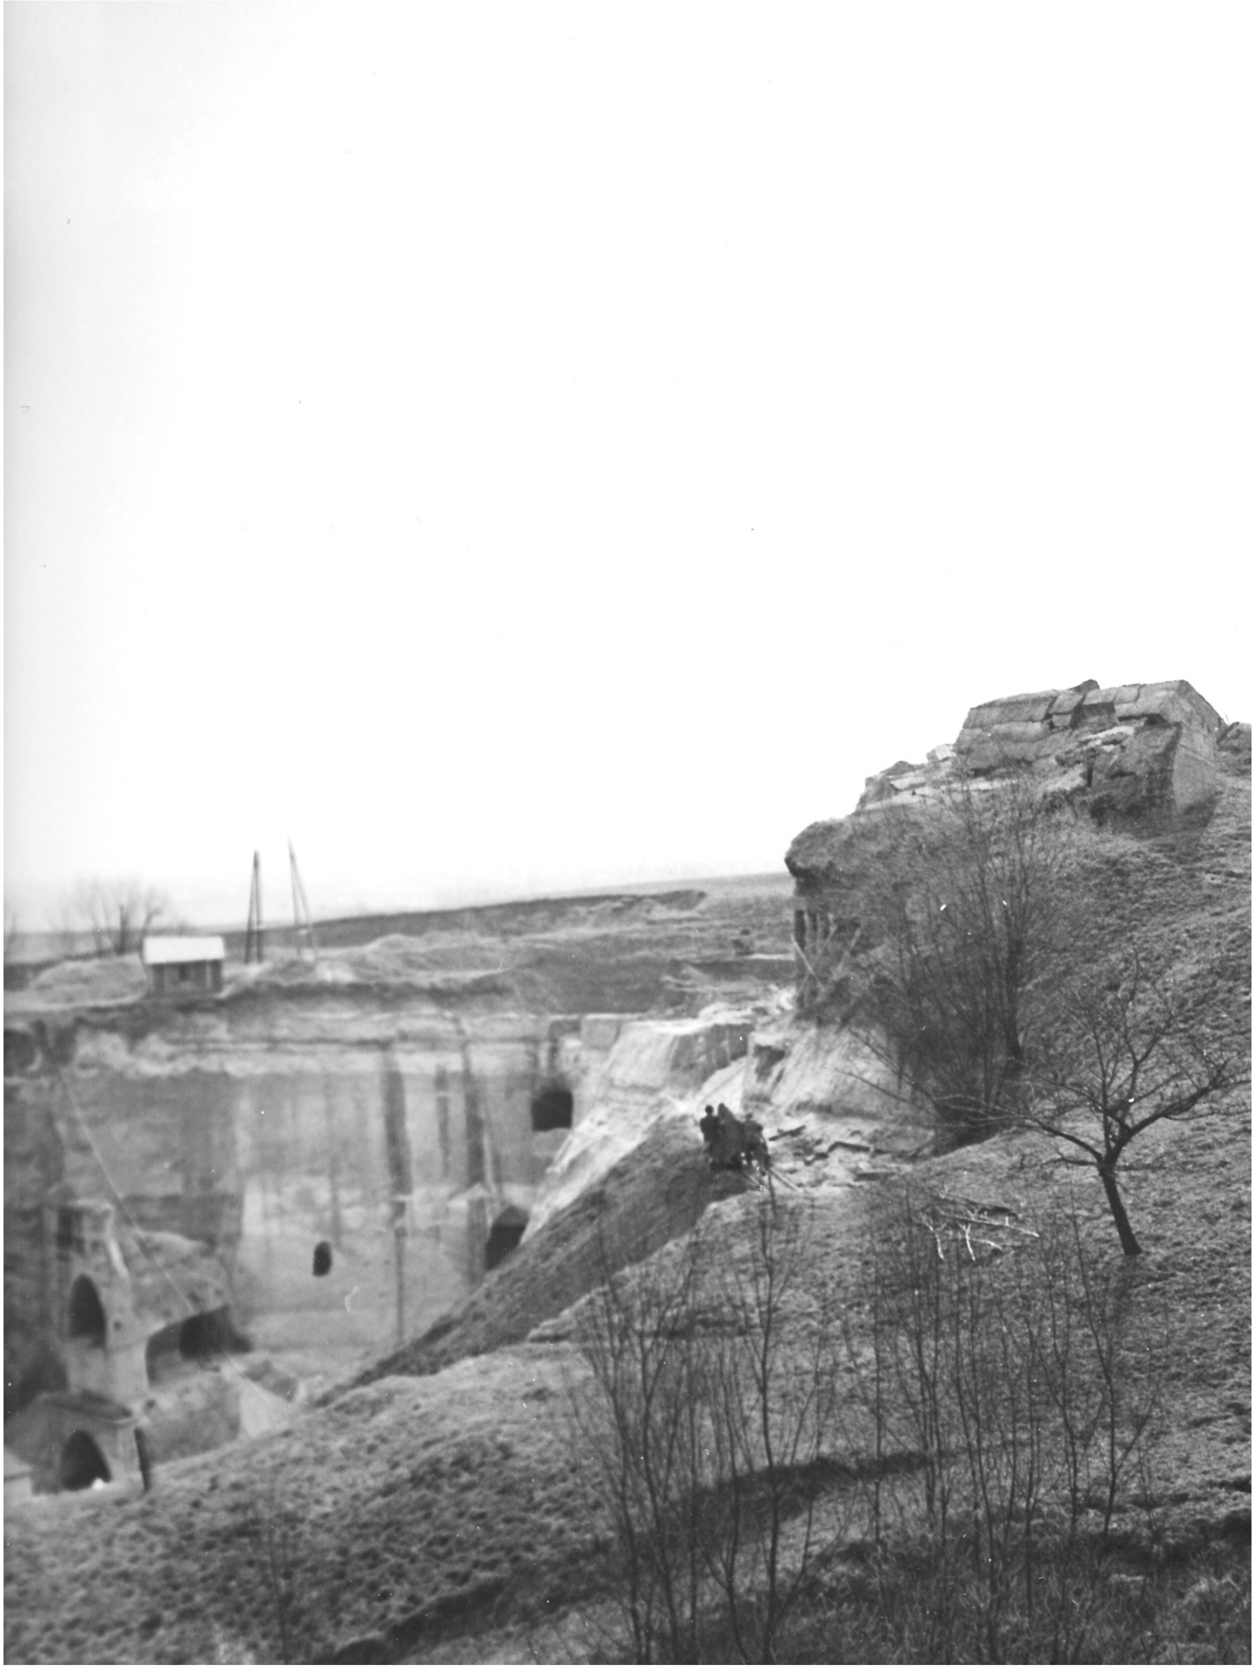


Figure D.407: 1944 photograph of Bergkristall entrances, clearly showing at least three levels of tunnels [Sammlung Franz Jakob, courtesy of Andreas Sulzer]. Surviving maps only show the uppermost level of tunnels, not the lower levels.

Die aus Beton, bzw. Stahlbeton hergestellten 4.5 bis 6.0 m breiten Stollenräume von mehr als 7.0 km Länge, mit allen wieder instandsetzbaren modernsten Einrichtungen (Lüftuntungen, Heizungen, Beleuchtungen, Installation, sanitären Einrichtungen, etc.), Trockenheit und idealer geographischer, verkehrstechnischer und geologischer Lage (ehem. feinmechanischer Betrieb), wäre die geeigneteste Voraussetzung zur Unterbringung einer Atomforschungsstätte.

Dipl. Arch. J/W Vienna, 17 Nov. 1955

Project: “Atomic Pile” (Research Site)

The proposal essentially comprises the evaluation of an existing underground plant for the installation of 1 or 2 atomic piles.

The utilization of this plant, which is particularly suitable for such purposes, and the installation of one or two “swimming-pool reactors” would result in a substantial reduction in costs compared with a completely new plant in a similarly favorable location and given conditions.

Inspired by a newspaper report, according to which the Energy Commission in Austria is planning a nuclear power plant on the Danube, I take the liberty of drawing attention to the unique opportunity of using an already existing underground plant, which is particularly well located and equipped with all the advantages.

This bomb-proof underground facility, with an existing usable area of approximately 45,000 m2 and sidings, could be expanded to 60,000 m2 of usable area.

The 4.5 to 6.0 m wide tunnels made of concrete or reinforced concrete, more than 7.0 km long, with all the modern facilities that can be restored (ventilation, heating, lighting, installation, sanitary facilities, etc.), dryness and ideal geographical, transport and geological location (former precision engineering plant), would be the most suitable conditions for housing an atomic research facility.

Diese Anlage wurde 1944/45, also in einem Jahr, mit einem Kostenaufwand von mehr als 500 Millionen Schilling und hunderte Toter, als technische Großleistung errichtet.

Nach Übernahme durch die Amerikaner und fast vollständiger Demontage durch dieselben, übernahm die russische Besatzungsmacht die Anlage, welche die restliche Demontage durchführte.

Durch unzulängliche Teilsprengungen versuchte man die Anlage zu zerstören. Untersuchungen ergaben, daß die entstanden Teilschäden keine nachhaltigen Zerstörungen verursachten, in verhältnismäßig kurzer Zeit mit geringen Mitteln und Materialaufwand instandzusetzen sind.

Diese Anlage gäbe mit ihren bestehenden Kanalsystemen, Abwasser- und Kläranlage, sowie geologischen Verhältnissen die preiswerteste Ausnützung für ein Atomforschungszentrum, eventl. Atomkraftwerk samt Labors und Forschungsstätte.

Die außerordentliche Lage in der Nähe der Donau, anliegender Straße, Bahnanschluß, etc. würde weitere bedeutende Kosteneinsparungen ergeben.

Außserdem würden nur geringe Ablösen der oberirdischen Grundbesitze nötig sein, da bereits die Besitzer einmalige Ablösen erhielten, oder sich durch Abverkauf der 1945 zurückgelassenen Materialien und Güter entschädigten.

Das Nutzwasser kann 2–3 m unter der derzeitigen Sohle in reichlichem Maße (Zufluß von nahegelegenem Fluß) für Kühlung, Schutz gegen radioaktive Strahlung, Regelung der Spaltgeschwindigkeit, sanitäre Einrichtung, etc. leicht entnommen werden.

This facility was built in 1944/45, in one year, at a cost of more than 500 million shillings and hundreds of deaths, as a major technical achievement.

After being taken over by the Americans and almost completely dismantled by them, the Russian occupation forces took over the plant and carried out the remaining dismantling.

Attempts were made to destroy the plant by inadequate partial demolitions. Investigations showed that the partial damage caused no lasting destruction and could be repaired in a relatively short time with little resources and materials.

This plant, with its existing sewer systems, sewage and wastewater treatment plant, as well as geological conditions, would provide the most economical utilization for a nuclear research center, possibly a nuclear power plant, including laboratories and research facilities.

The extraordinary location near the Danube, adjacent road, railroad connection, etc. would result in further significant cost savings.

In addition, only small redemptions of the above-ground properties would be necessary, since the owners already received one-time redemptions, or compensated themselves by selling the materials and goods left behind in 1945.

The service water can be easily extracted 2–3 m below the present invert in abundance (inflow from the nearby river) for cooling, protection against radioactivity, regulation of fission rate, sanitary facilities, etc.

Durch Einziehung von Stahlbetondecken samt erforderlichen Pfeilern (Gründung in geringer Tiefe 2–4 m auf Granit), Einbau von Betontanks für die “Schwimmbad-Reaktoren”, sowie Unterbringung der Kraft-Maschinenen, Heizwerk, Labors und Forschungsstätten in den Stollen wäre das generelle Zentrum zu schaffen.

Oberirdisch könnten die Allgemeinbaulichkeiten (Biologisch-medizinische Abteilung, Bibliothek, Archiv, Lese- und Vortragsaal, Forschungsstelle mit Pflanzenhaus und Tierfarm, Kühlturm, Büroräume, Werkstätten, Kantine und Küche, Empfangsräume, Personalzimmer, Förderanlagen, etc.; Tankstelle, Parkplatz, Trafostation etc.) in organischer Reihung, zweckmäßig und dem Gelände angepaßt erstellt werden.

Die gesamte Planung und Sammlung der Erfordernisse müßte durch sämtliche einschlägigen Fachgruppen (Experten) ermittelt, eventl. nach eigenenden Studien im Ausland ergänzt werden und an Hand eines Modelles demonstriert werden.

Anschließend wären die Kosten zu ermitteln und nach Klärung der rechtlichen und finanziellen Verhältnisse eine abschnittsweise Ausfúhrung der Anlage angezeigt.

Durch verhältnismäßig einfache Absperrung des Gebietes und Aufbau der oberirdischen Teilanlagen würde eine gewisse Geheimhaltung gewährleistet erscheinen.

Ich fühle mich verpflichtet, auf diese besonderen Umstände besonders aufmerksam zu machen, da:

1. dem österr. Volk unter Nutzung des bereits vorhandenen nur Vorteile erwachsen können,

The general center could be created by the installation of reinforced concrete ceilings with the necessary pillars (foundation at a shallow depth of 2–4 m on granite), installation of concrete tanks for the “swimming pool reactors,” as well as accommodation of the power machines, heating plant, laboratories and research facilities in the tunnels.

Above ground, the general buildings (biological-medical department, library, archives, reading and lecture hall, research center with plant house and animal farm, cooling tower, offices, workshops, canteen and kitchen, reception rooms, staff rooms, conveyors, etc.; gas station, parking lot, transformer station, etc.) could be created in an organic order, functional and adapted to the terrain.

The entire planning and collection of the requirements would have to be determined by all relevant professional groups (experts), possibly completed after own studies abroad and demonstrated on the basis of a model.

Subsequently, the costs would have to be determined and, after clarification of the legal and financial circumstances, a section-by-section execution of the plant would be indicated.

By relatively simple cordoning off of the area and construction of the above-ground sections, a certain degree of secrecy would appear to be guaranteed.

I feel obliged to draw special attention to these special circumstances, since:

1. the Austrian people can only benefit by using what is already available,

2. große finanzielle Investitionen erspart werden,

3. ein vorhandenes, brachliegendes—für andere Zwecke schwer verwendbares—Bauwerk einer tatsächlich guten Sache zugänglich gemacht würde,

4. eine der modernsten, sichersten und eigenwilligsten Anlagen der Welt entstünde und

5. die Kenntnisse der noch am Leben befindlichen Ingenieure, Bauleiter und Techniker, sowie teilweise vorhandene Unterlagen kostensparende Mitarbeit, Auswertung ihres Wissens zur besten Ausnutzung der vorhandenen Anlagen ergeben könnten.

Es wird nochmals betont, daß diese Anregung zum größten Nutzen der Wissenschaft, der praktischen Auswertung zur Energiegewinnung, rein finanzieller Art durch Nutzung vorhandener großzügigster bombensicherer Anlagen und zum besonderen Ruf österr. Technik, sowie dem gesamten Volke selbst sein könnte.

Es ist als sicher anzunehmen, daß eine unvoreingenommene Prüfung die günstige Lage, Nutzbarmachung mit verhältnismäßig geringen Mitteln und diese einmalige Gelegenheit erkennen lassen wird. Die aufgewendete Mühe und erforderlichen Projektunterlagen werden sich reichlich bezahlt machen.

Außerdem erscheint es besonders wichtig, nochmals darauf hinzuweisen, das Wissen der ehemals am Neubau des Werkes maßgeblich beschäftigten Fachkräfte zum Wohle und Nutzen eines großen Werkes nicht verloren gehen zu lassen.

2. large financial investments are saved,

3. an existing, fallow—for other purposes hardly usable—building would be made accessible to an actually good cause,

4. one of the most modern, safest and most unique facilities in the world would be created, and

5. the knowledge of the still living engineers, construction managers and technicians, as well as partially existing documents could result in cost-saving cooperation, evaluation of their knowledge for the best utilization of the existing facilities.

It is emphasized again that this suggestion could be to the greatest benefit of science, the practical evaluation for energy production, purely financially by use of existing most generous bomb-proof plants and to the special reputation of Austrian technology, as well as the entire people itself.

It is safe to assume that an unbiased examination will reveal the favorable situation, utilization with relatively small means and this unique opportunity. The effort spent and the required project documentation will pay off in abundance.

In addition, it seems particularly important to point out once again not to let the knowledge of the skilled workers, who were formerly significantly involved in the construction of the plant, be lost for the good and benefit of a large plant.

Nach dem Ausbau eines solchen “Atommeilers” mit angeschlossener Forschungsstätte hätte das neutrale freie Österreich den Anschluß an die Wissenschaften, Forschung und Technik der Welt gefunden.

Billige Energiegewinnung, Fortschritt in der Gesunderhaltung des gesamten österr. Volkes und erforderliche Schritthaltung der ausländischen Wissenschaft gibt unserem Volke die Möglichkeit einer tatsächlichen Selbstständigkeit.

In Erwartung, daß vorliegende Anregung günstige Aufnahme findet, stehe ich gerne zu weiteren Auskünften, Vorschlägen und Unterlagen zur Verfügung.

After the development of such an “atomic pile” with an associated research facility, neutral, free Austria would have been connected to the sciences, research and technology of the world.

Cheap energy production, progress in maintaining the health of the entire Austrian people, and the need to keep pace with foreign science will give our people the possibility of actual independence.

In the expectation that this suggestion will be favorably received, I am at your disposal for further information, suggestions and documents.

SUBJECT Underground Factories and Storage Places.

TO Chief of Mission, Strategic Service Unit, War Department, United States Forces, European Theater, APO 633, U.S. Army

1. Inclosed herewith are descriptions of 59 Underground Factories and Storage Places located in a given area.

2. Since these targets are of relatively recent construction and represent a large amount of potential productive capacity of aircraft and oil products, their Air Intelligence interest is obviously great. Therefore it is the earnest desire of this office to obtain up-to-date information as to their present activity, if any.

3. If a conference could be arranged with your office a full discussion might then be had as to any possible help that your office might give in connection with the above project.

Figure D.414: The cover letter for the U.S. military's "Special Projects" investigation of Austria is prominently labelled "Underground Pile" and underlined three times to emphasize the importance of those words [AFHRA folder 570.6501A 1945–1946; AFHRA C5098 frame 935]. Did the U.S. military find evidence of a wartime "underground pile" (fission reactor) in Austria, for example at St. Georgen/Gusen? Or was it just a remarkably excessive way of labeling that document to go with the "pile" of other documents on underground facilities? Where is the report that this cover letter referred to?

Underground Installations in Austria

Assistant Chief of Staff, A-2, Air Division, Headquarters,
United States Forces in Austria, APO 777, US Army.
Attn: Colonel Henry M. Zeller

1. Information at this division indicates that a Lieutenant Holbitzell of the Topographic and Terrain Section, G-2 Division, USFA, is making a study of underground installations in Austria.

2. This office is interested in such information and would appreciate it if a copy of the study and any pertinent information thereto can be forwarded. Additional information is desired giving the total number of installations listed with pin-point locations and whether such installations had been used as underground manufacturing sites.

1.	Colonel Masson	J.J. Stone, Special Projects	6 Mar 46	1. Reference is made to the attached letter, subject as above, to AC/S, A-2, USFA. 2. The information that this officer was making a study on underground installations was obtained by one of our field teams located down near Munich. It is understood that this officer has spent considerable time and has obtained quite a bit of information by interrogations locating plants, etc. 3. We may not be able to obtain complete copies of all the work this officer has done because it would probably involve a considerable amount of typing and office work. However, if we can get Colonel Zeller to give us a preliminary report as to the extent and value of the information, then possibly at a later date we may be able to send someone to collect this data for our files. 4. I believe this officer's study may be one concerned with general terrain data and information, however in the compiling of this information he has undoubtedly run across data on underground factories and it would be helpful to have this in our files.

Figure D.419: Inside the Bergkristall tunnel complex now. [Courtesy of Rudolf Haunschmied]

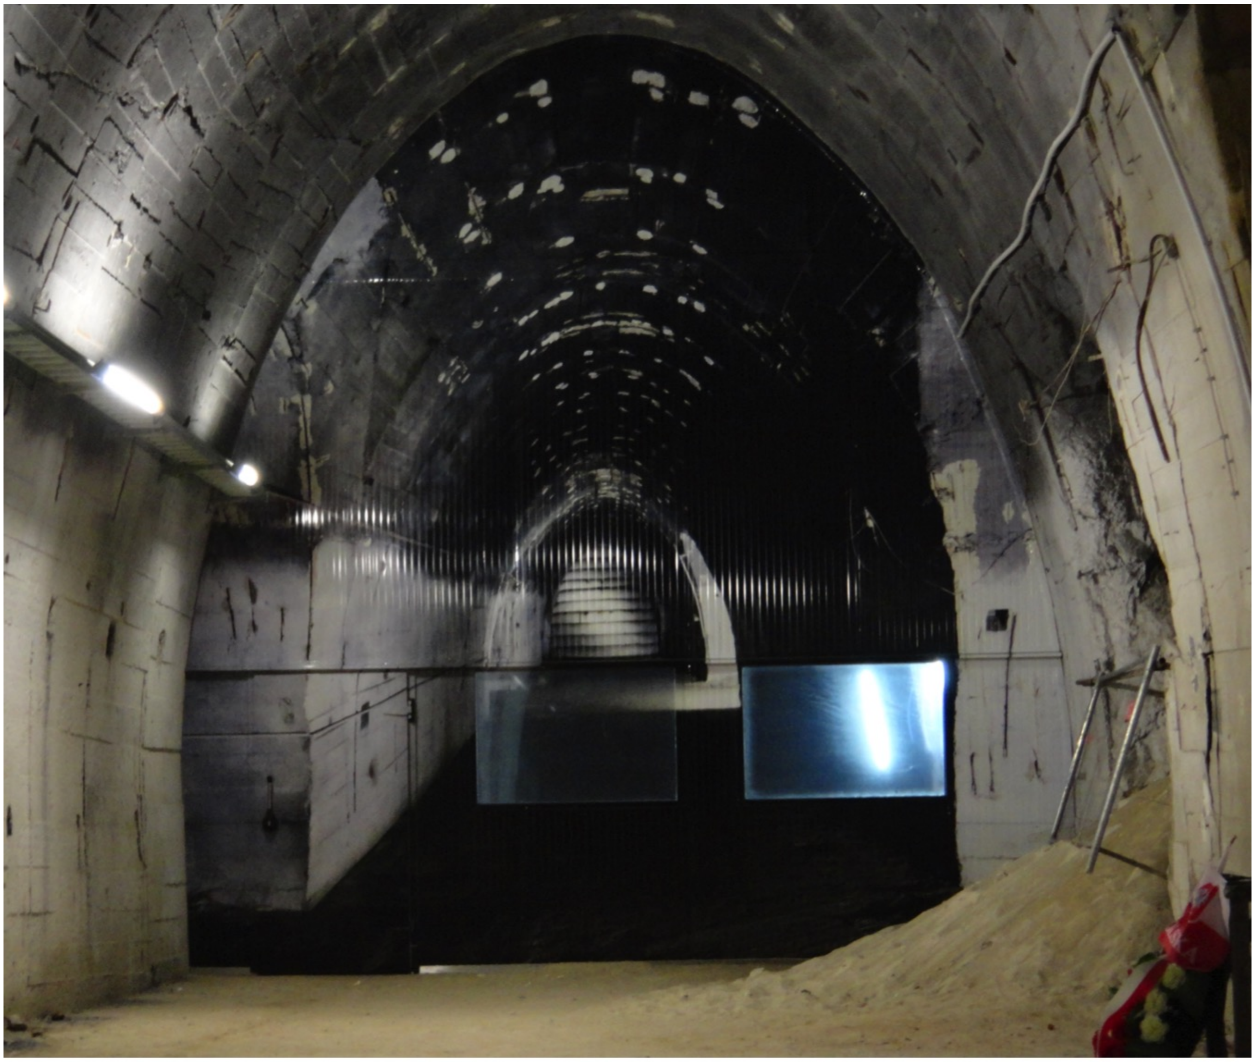

Figure D.420: In the Bergkristall tunnel complex, the Austrian government has installed a gas-proof transparent plastic barrier between the publicly accessible tunnels and those beyond, in order to block radioactive gases that are coming from the inaccessible tunnels. Even so, the radioactive gas levels in the publicly accessible tunnels are so great that the Austrian government has stipulated that (1) they can only be open to public visitors twice per year, (2) they must be thoroughly ventilated for many hours before each public visiting day, and (3) visitors cannot remain in the tunnels longer than one hour. [Courtesy of Rudolf Haunschmied]

5. A possible fission reactor at Unterraderach near Friedrichshafen

A Signaler d'Urgence. Undated but apparently late 1943. [Archives of the French Army Ministry of Defense, courtesy of Andreas Sulzer]

On a decouvert en Allemagne l'existence d'une usine spéciale qui fabrique des engins nouveaux et redoutables: Projectiles de 200 Kgrs, à enveloppe d'aluminium qui seraient lancés par dessus le Détroit. Ces engins exploseraient à l'arrivée et détraraient tout ce qui est vivant dans un rayon de 20 Km.	In Germany was discovered the existence of a special factory which manufactures new and formidable machines: 200-kilogram projectiles, with an aluminum envelope, which would be launched over the [English] Channel. These devices would explode upon arrival and destroy everything that is alive within a radius of 20 km.
L'usine se trouve dans une dépression de terrain assez accentuée (40 m.), elle est protégée par 40 pièces de D.C.A. [défense contre l'aviation] et à la moindre alerte, est camouflée par un nuage de fumée.	The factory is located in a fairly deep depression (40 m.), it is protected by 40 anti-aircraft guns, and at the slightest alert is hidden by a cloud of smoke.
L'emplacement de cette usine est dans le WURTEMBERG dans le triangle formé par FRIEDRICHSHAFEN au Sud, MARKDORF au NORD-OUEST, OBERTEMINGEN au NORD.	The location of this plant is in WURTEMBERG in the triangle formed by FRIEDRICHSHAFEN in the south, MARKDORF in the northwest, OBERTEMINGEN in the north.
D'apres le croquis ci-joint, la dépression de terrain dans laquelle se trouve l'usine, parait être orientée sensiblement EST-OUEST, a son extrémité EST aboutit la route venant de FRIEDRICHSHAFEN, qui, à ci-cet, endroit tourne brusquement à droite.	According to the attached sketch, the depression of the ground in which the factory is located, seems to be oriented essentially EAST-WEST, at its EAST end ends up on the road coming from FRIEDRICHSHAFEN, which, at this point, turns abruptly to the right.
Les tirs doivent commencer fin Décembre ou commencement de Janvier.	Firing must start at the end of December or beginning of January.
Ce sont peut-être les représailles annonçées par le Maréchal GOERING.	These may be the reprisals announced by Marshal GOERING.
Il est extrèmement difficile et dangereux de s'approcher de cette usine. Tout le personnel employé doit vivre dans l'enceinte même de l'usine et ne peut sortir sous aucun prétexte.	It is extremely difficult and dangerous to approach this factory. All staff employed must live within the factory premises and may not leave under any circumstances.
Ces renseignements sont absolument sûrs, l'usine a été visitée	This information is absolutely certain, the plant has been visited

Autre renseignement donné par un officier Alsacien travaillant en Allemagne au sujet de l'arme secrète:

Les Allemands avaient préparé pour la Iere quinzaine d'Aoùt, le bombardement de Londres.

Ce bombardement devait avoir lieu au moyen d'engins qui auraient lancé de BERLIN même des bombes à gaz et à microbes propulsées par un dispositif à air comprimé. Cela ne s'est pas réalisé jusqu'a présent mais semble vouloir l'être bientôt.

Other information regarding secret weapons provided by an Alsatian officer working in Germany:

The Germans had prepared for the first fortnight of August, the bombing of London.

This bombardment was to take place using devices that would have thrown gas and microbial bombs from BERLIN itself, propelled by a compressed air device. This has not been achieved so far but seems to be happening soon.

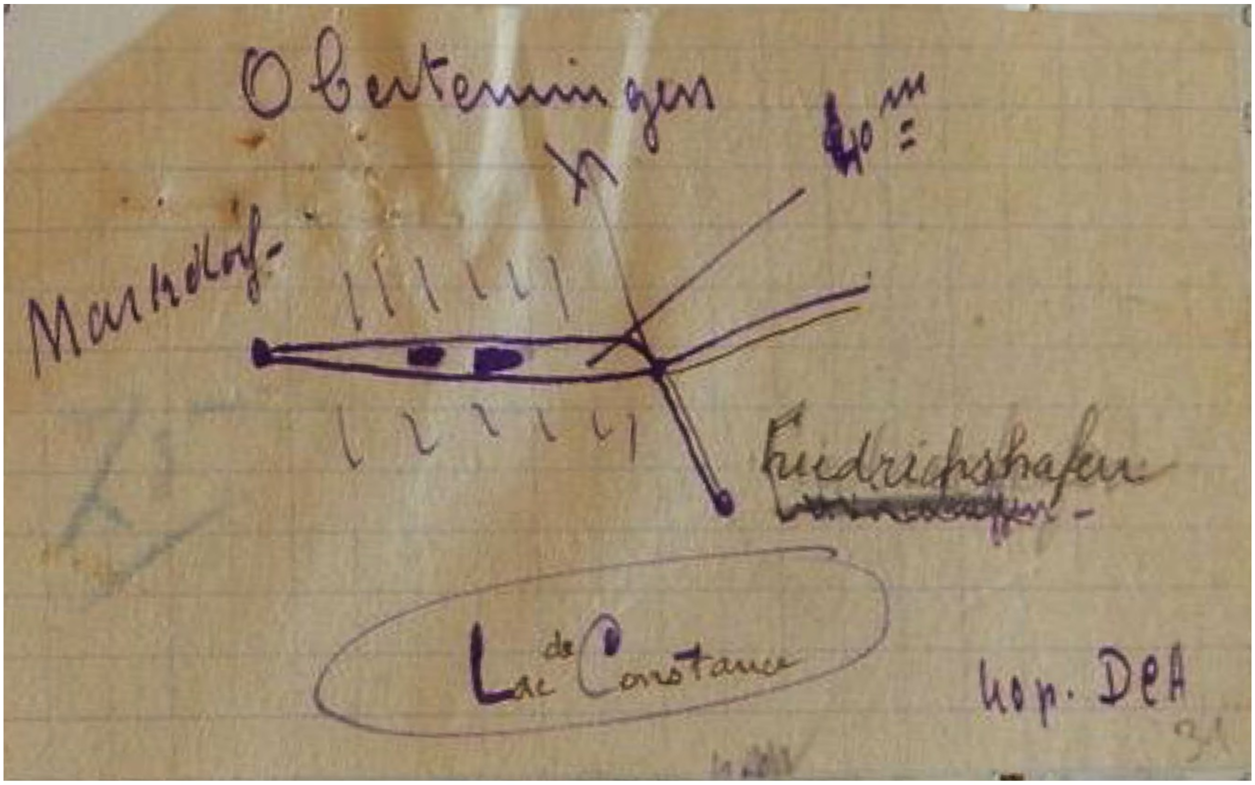

Figure D.421: Wartime French map showing the location of a highly secret nuclear facility near Friedrichshafen that may have been a fission reactor.

S. McClintic, Headquarters U.S. Strategic Air Forces in Europe, Office of the Director of Intelligence, to George C. McDonald. 6 January 1945. Big Ben (Rockets). [AFHRA A5734 electronic version p. 1092]

[...] At UNTERRADERACH, near FRIEDRICHSHAFEN, there is a large semi-underground factory which was constructed early last winter where strange experiments were taking place. Heavy clouds of smoke filled the sky in the day and at night a red glow. The experiments caused the earth to shake. These experiments are with atoms and when the experiments proved successful the plant went into operation. Workmen were not allowed to leave the factory. [...]

[This appears to be the same location as that described in the previous French report. Could this have been the location of a working fission reactor?

- The work was atomic, and so secret that "workmen were not allowed to leave the factory," as stated by both the American and French intelligence reports.
- The area is on the southern border of Germany, far from Allied forces at that time.
- The area is also on the coast of the Obersee Bodensee, which could have supplied as much water as needed to cool the reactor. The heavy clouds of smoke might have been steam from water coming out of the reactor.
- If the reactor was not operated very carefully, times at which it briefly went supercritical, or occasional buildups of steam, hydrogen, or other gases, might have "caused the earth to shake."
- If there was no containment structure around the reactor, there might have been a visible glow at night.
- "When the "experiments... with atoms... proved successful the plant went into operation" to produce something new and dangerous.
- The plant produced material for "200-kilogram projectiles, with an aluminum envelope, which... would explode upon arrival and destroy everything that is alive within a radius of 20 km." While the radius of destruction seems to have been exaggerated by the French intelligence report, a large radius of destruction for a small device definitely sounds nuclear, consistent with the plant involving "experiments... with atoms."
- One possible explanation that is consistent with the very limited available data is that the plant was producing fission fuel for ∼200-kg low-yield tactical fission weapons such as those described by Eric Schumann (pp. 4246–4248) and Werner Grothmann (pp. 4271–4277). Another possibility is that the plant was producing irradiated fission reactor fuel that could be combined with conventional explosives in a ∼200-kg bomb to make a radiological "dirty bomb."
- This plant may have been related to the Forschungsanstalt Graf Zeppelin in Friedrichshafen, and specifically to the brothers Georg Madelung (German, 1889–1972, a bomb and aerospace expert) and Erwin Madelung (German, 1881–1972, an atomic physicist) who worked there.

Can other reports about this facility be found in archives?

Can the possible site near Friedrichshafen be located and inspected now?

This area is known to have had a plant producing liquid oxygen for the A-4 (V-2) rockets, but what is described in the two documents above sounds quite different than a liquid oxygen plant. It seems likely that there were several different advanced weapons plants located in that area.]

REPORT FROM CAPTURED PERSONNEL AND MATERIAL BRANCH

Information from four German army Ps/W captured in France in August-September 1944 and from one P/W captured in Italy in June 1944. Obtained in the U.S. 1-2 November 1944. Believed reliable.

I. RIBNITZ -- WALTHER BACHMANN FLUGZEUG K.G. (Airplane Repair Works).
II. WIK (NEAR KIEL) -- PURPORTED SECRET WEAPONS FACTORY.
III. NEURUPPIN AIRPORT -- ASSEMBLY OF JU-88's.
IV. ST. POELTEN -- WAR INDUSTRIES.
V. OBERDORF (NEAR KAUFBEUREN) -- LARGE FACTORY UNDER CONSTRUCTION.
VI. FRIEDRICHSHAFEN -- FACTORY BUILT INTO HILLSIDE.
VII. GERMAN PRODUCTION OF PRIME MOVERS.
VIII. TIME FUZE PRODUCTION.

SECRET

1370 (P. 4)

VI. FRIEDRICHSHAFEN -- FACTORY BUILT INTO HILLSIDE:

P/W heard from a fellow P/W about a factory built near Friedrichshafen into a hillside since the war, with its own connecting RR, employing 8-10,000 German garrison prisoners who had no contact with the outside world. All freight cars leaving this factory were sealed.

VII. GERMAN PRODUCTION OF PRIME MOVERS:

The following information on German production of prime movers (Zugmaschinen) prior to the loss of France and portions of Poland was obtained from a 45 year old P/W, director and employee of the Adler Werke, Frankfurt A.M., from 1925 to October 1941 when he was transferred to the Heereswaffenamt (Army Ordnance Office) Paris, an agency dominated by the Adler Werke and set up originally to coordinate prime mover fabrication in France and Germany. On 18 August 1944, he was commissioned a 2nd Lt. The following week he was captured. All of the firms listed below were dependent to some extent on French industry.

6. A possible fission reactor at an underground facility in Berlin-Lichterfelde

RENSEIGNEMENT. Origine: Officier de l'E.M.G.G. 18 January 1950. [Archives of the French Army Ministry of Defense, courtesy of Andreas Sulzer]

I^{o}.—RENSEIGNEMENTS D'ARCHIVES.—

a)—Docteur ENGEL
—Ingénieur allemand travaillant à ANDILLY pour le compte de l'O.N.E.R.A.

b)—Société X......

I^{o}.—RENSEIGNEMENTS PROPREMENTS DITS.—

ENGEL (a) aurait été, à la fin de la guerre, après avoir été Directeur de SKODA, Chef des recherches du groupe d'armement HERMANN GOERING; à ce titre, il aurait eu rang d'égalité avec les Directeurs des six usines de ce groupe dont les raisons sociales auraient été: SKODA, EXPLONIA, etc... Il aurait reçu le pouvoir absolu de prélever dans ces 3 usines tout matériel ou tout personnel qu'il lui aurait semblé bon.

Par ailleurs, un groupe français que l'on désignera par "Société X..." (b) et qui en tout cas ne serait pas SCHNEIDER, aurait détenu 28 % des actions de SKODA et les Allemands n'auraient pas pu s'en emparer. Le groupe qui détiendrait ces actions exercerait actuellement so activité à PARIS, où il se liverait à la vente de divers matériels, dont des armes.

Le 6 Janvier 1950, le Dr. ENGEL (a), à la recherche d'instruments de laboratoire, est entré fortuitement en relations avec cette Société X... dont il aurait ignoré l'existence auparavant. Il y aurait été reconnu par des personnes d'ailleurs inconnues de lui, et des membres de cette société lui auraient dit ce qui suit:

I^{o}. —ARCHIVAL INFORMATION.—

a)—Doctor ENGEL
—German engineer working at ANDILLY for O.N.E.R.A.

b)—Company X........

I^{o}.—PROPERTY INFORMATION.—

ENGEL (a) was, at the end of the war, after having been Director of SKODA, Head of Research of the HERMANN GOERING armaments group; as such, he had equal rank with the Directors of the six factories of this group whose corporate names were: SKODA, EXPLONIA, etc... He was given the absolute power to take from these 3 plants any equipment or personnel that he thought were appropriate.

In addition, a French group that will be referred to as "Society X..." (b) and which in any case would not be SCHNEIDER, held 28 % of SKODA's shares and the Germans did not take them. The group that held these shares currently operates in PARIS, where it sells various items, including weapons.

On 6 January 1950, Dr. ENGEL (a), in search of laboratory instruments, fortuitously entered into a relationship with this Society X... of whose existence he was previously unaware. He was reportedly recognized by people unknown to him, and members of this society reportedly told him the following:

“Au cours de leur avance, les Soviets se seraient emparés du centre d’essais de PIEBRANZ, qu’aurait dirigé ENGEL (a). Ils auraient gardé trois des ingénieurs de ce centre et bien qu’ENGEL eut détruit, avant l’armistice, dans la région de MUNICH, les documents qu’il aurait évacués, les Russes auraient pu, avec l’aide de ces trois ingénieurs, reconstituer les projets en cours d’étude à PIEBRANZ, à la fin de la guerre.” [...]

Plus loin, le même article ajoute:

A peu près à ce moment (1944?) la Direction de l’Étude de l’Uranium passa de ESAU (c) à GERLACH (f).

A côté de cette version officielle, les faits suivants ont été rapportés par le Docteur ENGEL (a) au cours d’une conversation, à PARIS, le 22 Décembre 1949.

En 1944, à LICHTERFELD, une pile atomique aurait été montée par THIESSEN (g), ARDENNE (h) et ESAU (c) dans un abris souterrain spécialement aménagé, gardé et très surveillé. Leur travaux auraient abouti à la séparation rapide de l’Uranium 235 et les Allemands se seraient trouvés à quinze jours de la réalisation de la bombe atomique quand un raid de blindés soviétiques, perçant le front et s’avançant en flèche de 30 Kms, se serait emparé de LICHTERFELD.

La colonne aurait été parfaitement au courant de l’existence de l’organisme de recherches et même de la disposition des lieux, car les Russes auraient pénétré directement dans l’usine souterraine sans même qu’on ait pu y donner l’alerte. Le matériel aurait été aussitôt photographié minutieusement, puis démonté et expédié à ATOMGRAD.

ESAU (c) n’aurait pas été pris, mais se serait rendu aux Américains à quelque temps de là. Ce serait lui qui leur aurait indiqué le procédé permettant d’isoler l’Uranium 235, procédé tellement plus rapide que ceux qui avaient été utilisés jusqu’alors, qu’il aurait permis aux Américains de gagner dix-huit mois sur la fabrication de la bombe.

“During their advance, the Soviets seized the PIBRANS test center, which ENGEL directed (a). They kept three of the engineers of this center and although ENGEL had destroyed, before the armistice, in the MUNICH region, the documents he evacuated, the Russians could, with the help of these three engineers, have reconstituted the projects under study in PIBRANS, at the end of the war.” [...]

Further on, the same article adds:

At about this time (1944?) the leadership of the Uranium Study passed from ESAU (c) to GERLACH (f).

In addition to this official version, the following facts were reported by Doctor ENGEL (a) during a conversation in PARIS on 22 December 1949.

In 1944, in LICHTERFELD, an atomic pile was allegedly assembled by THIESSEN (g), ARDENNE (h) and ESAU (c) in a specially equipped, guarded and highly guarded underground shelter. Their work supposedly led to the rapid separation of Uranium 235, and the Germans allegedly were fifteen days from completing the atomic bomb when a raid of Soviet tanks, piercing the front and advancing 30 Kms, seized LICHTERFELD.

The [Soviet] unit was apparently fully aware of the existence of the research organization and even of the layout of the premises, as the Russians entered the underground plant directly without even triggering an alarm. The material was immediately photographed thoroughly, then dismantled and shipped to ATOMGRAD.

ESAU (c) was not taken, but surrendered to the Americans some time later. It was he who allegedly told them the process for isolating Uranium 235, a process so much faster than those used until then, that it would have saved the Americans eighteen months in manufacturing the bomb.

La réalisation de cette deuxième bombe (la première celle de LOS ALAMOS étant au plutonium) et la possibilité de pour-suivre la production à un rythme très rapide, aurait motivé la décision du Président TRUMAN de faire lancer les bombes sur HIROSHIMA (la deuxième, dont il vient d'être parlé) et sur NAGASAKI (une troisième bombe, fabriqué en un temps très court grâce au même procédé).

The completion of this second bomb (the first one from LOS ALAMOS being plutonium) and the possibility of following the production at a very fast rate, may have motivated President TRUMAN's decision to drop the bombs on HIROSHIMA (the second, just mentioned) and on NAGASAKI (a third bomb, manufactured in a very short time using the same process).

7. Possible fission reactors in East Prussia

Heinrich Himmler's diplomatic contact, Muhammad Amin Al-Husayni, the Grand Mufti of Jerusalem. Translated and paraphrased in: Wolfgang G. Schwanitz. Review of Karlsch, Rainer; Petermann, Heiko, Für und Wider "Hitlers Bombe": Studien zur Atomforschung in Deutschland. *H-Soz-u-Kult, H-Net Reviews.* February 2009. [https://www.h-net.org/reviews/showrev.php?id=24129] For the rest of this reference, see pp. 4578–4579.

After 1945 the Grand Mufti said that the enemy espionage by "Jewish, English and American intelligence services" caused "the greatest damage." They were able to discover the locations of "atomic reactors" in East Prussia.

Royal Air Force Bomber Command. Campaign Diary August 1944. https://webarchive.nationalarchives.gov.uk/ukgwa/20070706054833/http://www.raf.mod.uk/bombercommand/aug44.html

26/27 August 1944

174 Lancasters of No 5 Group to Königsberg, which was an important supply port for the German Eastern Front. The route to the target was 950 miles from the No 5 Group bases. Photographic reconnaissance showed that the bombing fell in the eastern part of the town but no report is available from the target, now Kaliningrad in Lithuania. 4 Lancasters lost.

29/30 August 1944

189 Lancasters of No 5 Group carried out one of the most successful No 5 Group attacks of the war on Königsberg at extreme range. Only 480 tons of bombs could be carried because of the range of the target but severe damage was caused around the 4 separate aiming points selected. This success was achieved despite a 20 minute delay in opening the attack because of the presence of low cloud; the bombing force waited patiently, using up precious fuel, until the marker aircraft found a break in the clouds and the Master Bomber, Wing Commander J Woodroffe, probably No 5 Group's most skilled Master Bomber, allowed the attack to commence. Bomber Command estimated that 41 per cent of all the housing and 20 per cent of all the industry in Königsberg were destroyed. There was heavy fighter opposition over the target and 15 Lancasters, 7.9 per cent of the force, were lost.

[Siegfried Flügge, who was probably the top nuclear physicist in the German nuclear weapons program, worked for many different organizations that were all involved in the nuclear program, apparently serving to coordinate the scientific details of all of their activities. Intriguingly, he was appointed to a professorship at the University of Königsberg in East Prussia in 1944, near the end of the war, as Russian forces were advancing (p. 4998). That appointment only makes sense if there was a nuclear facility there that was deemed critical to the war, such as fission reactors breeding plutonium for nuclear weapons.

During the war, Königsberg had a large staff of inorganic chemists with world-class expertise in methods that would have been useful for reprocessing irradiated fuel from fission reactors. After the war, many of those chemists were interrogated by at least two teams from the U.S. Alsos Mission, which suggests that U.S. officials suspected the Königsberg chemists had been involved in nuclear work. See pp. 3930–3933.

There were tens of thousands of forced laborers working in and near Königsberg during the war. They are known to have worked with toxic chemicals such as ship paints and suffered the consequences [Jasiński 1994]. This labor pool might also have been used for hazardous nuclear work.

During the period 26–30 August 1944, U.K. Royal Air Force bombers, operating at the very limits of their range, devastated targets in and near Königsberg. That only makes sense if there were targets of great military value and urgency, such as a nuclear facility on the verge of producing enough fuel for nuclear weapons. It also explains the Grand Mufti's comment. The official Royal Air Force explanation that Königsberg was only attacked because it was a port does not seem sufficient, since the attack was mainly directed at surrounding targets other than the port, and Königsberg continued to be used as a port after the 26–30 August 1944 attacks.

Despite the Allied bombings and fierce offensives by Soviet forces, German troops successfully defended East Prussia until April 1945, rather than retreating to more central areas of Germany and using their strength to defend those. Once again, that only makes sense if there were something in East Prussia that Germany considered so important it had the potential to decide the outcome of the war, even very late in the war.

After the war, East Prussia was claimed as Soviet territory, even though it was geographically disconnected from any other Soviet territory, rather than allotting it to the surrounding countries, Poland or Lithuania. Again, that suggests something rather unusual was found there. (Of course, it did also provide a desirable seaport for the Soviet Union.)]

SUBJECT: Hypernitric acid, silicon complexes; Prof. R. Schwarz of Königsberg and Böckstein.

LOCATION OF LABORATORY

The department of Inorganic Chemistry, University of Königsberg was evacuated to a building belonging to the Werkstatt Rathausberg, Nassfeld above Böckstein/Bad Gastein, Austria. Nassfeld in an isolated valley (cirque), high in the Alps and is connected to Böckstein by 8 kms. of steep mountain path hardly as wide as a jeep.

Other laboratories in Nassfeld are the department of aeronautics, Göttingen, Prof. Eder; department of physics, Graz, Prof. Matossi.

GENERAL DESCRIPTION

The laboratory consists of 3 rooms containing relatively little equipment. There is some special glass apparatus for preparing silicon complexes in the absence of air or moisture. Larger equipment for the studies of ceramics, etc., include electric ovens, and a unit for measuring coefficients of expansion. Two small rooms contain chemicals and library material.

Prof. R. Schwarz is a well-known inorganic chemist. He is an editor of Gmelin's Handbuch, vice-president of the Deutsche Chemische Gesellschaft, and an authority on compounds of silicon. He published 20 scientific articles during the war (list appended). He left Königsberg late in 1944 and has been in the Böckstein area since then. The Nassfeld laboratory has been operating for only a few months and the staff consists of 5 people.

RESEARCH PROBLEMS

1. ATTEMPTS TO MAKE HYPERNITRIC ACID, HNO_4

The first reaction attempted was between nitryl chloride NO_2Cl and 100% H_2O_2. (Schwarz and Schmeisser). The reaction was unsuccessful, presumably because most of the NO_2Cl formed in the preliminary reaction $NOCl + O_3 \rightarrow NO_2Cl + O_2$. had the structure N = O instead of O the logical precursor of HNO_4.

```
N = O    O
 !       "
O        N = O
 !       !
Cl       Cl
```

The next reactions considered were between N_2O_5 or 100% HNO_3 and H_2O_2. $HNO_3 + H_2O_2 \longrightarrow HNO_4 + H_2O$

$$N_2O_5 + H_2O_2 \longrightarrow HNO_4 + HNO_3$$

When 100% H_2O_2 was used, (R. Schwarz and U. Gregor), both of these reactions proved to be extremely violent at temperatures as low as -80 deg. C; at the temperature of liquid air, however, the reactants could be mixed without risk. As observed in a proper apparatus, the HNO_4 formed began to decompose at -80 deg C. with the liberation of small amounts of O_2. The product appeared as a light yellow pulp. On warming to -30 deg much more O_2 was evolved, and the residue proved to be pure 100% HNO_3.

Aqueous solutions of HNO_4 proved to be much more stable. A mixture of 70% HNO_3 and 30% H_2O_2 was stable at + 20 deg C. With 75% HNO_3, O_2 is liberated slowly, and the temperature increases gradually to 60 degrees C over a period of 90 minutes, when there is a very sudden increase in temperature and the whole liquid explodes. When 80% HNO_3 is used, the explosion develops in 22 minutes; with 85% HNO_3, in 18 minutes. In each case great quantities of oxygen are evolved.

2. OTHER COMPOUNDS OF NITROGEN (M. SCHMEISSER).

$NO_2 + (CN)_2$ forms a yellow solid of unknown composition. The product is explosive and may also be of interest in chemical warfare. The reaction $NOCl + KCN \longrightarrow NOCN + KCl$ also yields an explosive.

3. COMPLEX COMPOUNDS OF SILICON (R. SCHWARZ AND C. DANDERS).

Investigations were continued of the 10 Si atom compounds discovered by Schwarz in 1937. The hydrolysis product of $Si_{10}Cl_{22}$ was finally found to be $Si_{10}(OH)_{10}O_6$, a solid white substance that burns in air. On heating in vacuum hydrogen is removed with the formation of an unsaturated compound similar to "Siloxen."

Recently a very large silicon chloride of the formula $Si_{25}Cl_{52}$ has been synthesized. This gigantic molecule (M. W. > 2500) is by far the largest inorganic compound known. It is an amorphous solid with properties like glass or rubber. It is only slightly plastic or extensible, inflammable in air, and easily hydrolyzed by moisture.

4. REFRACTORY MATERIALS (R. SCHWARZ AND H. TIELE).

Studies have been under way on materials intermediate between pure Al_2O_3 (Sinterkorund or Alsint) and the clays, with emphasis on the effect of mineralizing substances such as oxides and fluorides. Studies of crystal structure, coefficients of expansion and resistance to hydrofluoric acid were made of materials burnt at 1400 degrees C, 1600 degrees C, and 1800 degrees C.

Professor Dr. Robert Schwarz
(former Königsberg)

Nassfeld near Badgastein,

Report of the Investigations, made in the last time
in Königsberg and Nassfeld.

(as written by Prof. Schwarz)

1) R.Schwarz and M.Schmeisser

It was tried to obtain substantially the Hypernitric acid till yet unknown in formula and behaviour. First we have taken the way of reaction between the Nitrylchlorid NO_2Cl and 100 percent. H_2O_2.

NO_2Cl was made according to

$$NOCl + O_3 = NO_2Cl + O_2$$

But the reaction of the NO_2Cl with H_2O_2, H_2O or NaOH a.s.o. shows, that the constitution is not $N\overset{\nearrow O}{\underset{\searrow Cl}{=O}}$ as to be expected from the chlorid of the nitriacid, but $\overset{O}{N}$-O-Cl.

In according to this result the Hypernitriacid can not be found in this manner. Probably there exists an isomerism between the two compounds, but we have not been successful in finding the true $N\overset{\nearrow O}{\underset{\searrow Cl.}{\leftarrow O}}$

2) R.Schwarz and U.Gregor

Consequently was investigated the reaction between 100 percent. HNO_3 or also N_2O_5 and 100 percent. H_2O_2, where according to

$$HNO_3 + H_2O_2 = HNO_4 + H_2O \quad \text{or}$$

$$N_2O_5 + H_2O_2 = HNO_4 + HNO_3$$

the possibility of success is given.

We have found the following:

Between the acid or the anhydrid and 100 percent. H_2O_2 the reaction

- 4 -

C O N F I D E N T I A L

CONFIDENTIAL

C O N F I D E N T I A L

is so impetuous that one gets an explosion even at -80°C, but working at the temperature of liquid air, it is possible to mix the two compounds without risk. Measuring the process in a proper apparatus, it was found that the reaction begins about -80° C by forming a little quantity of O_2. The product in now a light yellow pulp. In growing warm, at -30° C a lively formation of Oxygen takes place and finally the residue proves as 100 percent. HNO_3.

In this way it is demonstrated that the Hypernitricacid max be existent and steady in an interval from - 80° C till -30° C.

Overgoing to aqueous medium we have found that a composition of 70 percent. $HNO_3 + H_2O_2$ (and 30 percent H_2O) is steady at + 20° C and more. A mixture of 75 percent is slowly decomposed by forming Oxygen and increasing the temperature till 60° C during 90 minutes, whereupon the temperature increases suddenly under explosion of the whole liquid. With a mixture of 80 percent this effect runs off within 22minutes till the explosion, with 85 percent in 18 minutes, always forming great quantities of Oxygen.

3) R.Schwarz and H.Wiele

We investigate the scientific base for high refractory materials, lieing between pure Al_2O_3 (Sinterkorund or Alsint) and the well known clay-products. In this way the synthesis of Mullit takes place. This effect became advanced by mineralising substances, as Oxides or Fluorids and other compounds. We investigate the effect of such mineralising substances for the formation of the crystal-structure and the behaviour of the material burnt at 1400° C, 1600° C, 1800° C special by measuring the coefficient of expansion and the resistance against Fluoricacid. A different influence of certain oxydes has been found concerning the coefficient of expansion, the resistance and the optical view of thin polished samples.

4) R.Schwarz and Chr. Danders.

Long chains of Silicon-compounds.

The investigation of Si-compounds with 10 Si-atoms as $Si_{10}Cl_{22}$, discovered by me in 1937 was continued. The formula of the products of hydrolyses from $Si_{10}Cl_{22}$ is finally found as $Si_{10}(OH)_{10}O_6$. The solid white substance is burning in the air. On heating in vacuum Hydrogen is going away by growing of a unsaturated silicon-compound of the manner of "Siloxen."

C O N F I D E N T I A L

In the last time we have succeeded in finding a Silicon-chlorine-compound of the formula $Si_{25}Cl_{52}$. This gigantic molecule with a molweight of more than 2500 is by far the largest in the whole inorganic chemistry. According to his size the compound is an amorphous solid substance with a character like glass or caout chouc. It is few plastic and extensible, inflamable on the air and easily hydrolicsed by moisture.

5) M.Schmeisser

At the reaction of $NO_2 + (CN)_2$ a yellow solid substance of an unknown formula is formed. This product is explosiv and perhaps therefore interesting as a new explosiv substance or chemical warfare agent. Also the compound formed according $NOCl + KCN \rightarrow NOCN$ is explosive.

ALSOS MISSION

Ref: CPS/291

(Rear) APO 887
7 September 1945

SUBJECT: The Evacuated Chemical Institute of the University of Königsberg Böckstein-Nassfeld, (Supplementary Report)

1. Most of the work of this Institute is described in Alsos Report CAB/235. Additional descriptive material is attached to the original of the present supplementary report.

2. Of the seven investigations recently carried out by the Institute:

(a) An attempt to prepare pernitric acid by the interaction of hydrogen-peroxide and NO_2Cl;

(b) The reaction of 100% hydrogen-peroxide with pure nitric acid or nitrogen pentoxide;

(c) The nature and properties of refractory materials;

(d) The preparation and properties of long-chain silicon chlorides;

(e) The reaction between nitrogen dioxide and cyanogen;

(f) An investigation of sulfur monoxide (work done entirely at Königsberg);

(g) Organic syntheses in the "hot-cold tube" (see par. 3);

the first five (a) - (e) were supported by the Forschungsführung der Reichsluftfahrtministerium (RLM) and the last, (g), by the Reichsforschungsrat (RFR).

3. The "hot-cold tube" (Abschreckrohr), a water-cooled quartz tube surrounding a much smaller metal tube heated to high temperature, was used to study the polymerization of acetylene to toluene and styrene. This is without practical value because of the great need of acetylene in rubber synthesis. The catalytic oxidation of ethylene to formaldehyde and acetaldehyde and the combination of acetylene and carbon monoxide to form propiolaldehyde were also studied with the same apparatus. Part of this work has already been published (Ber. d. deutsche chem. Ges., 76, 957 (1943)).

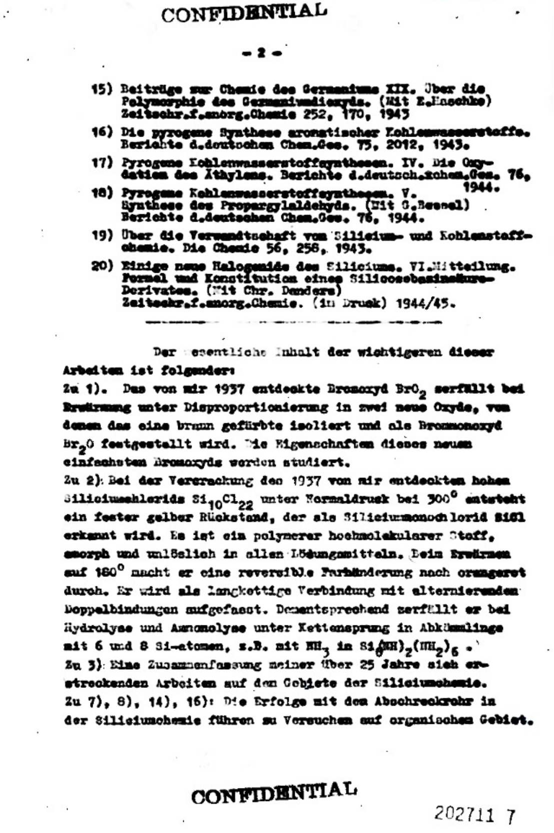
Übersicht
über meine in den Jahren 1939 - 1944
durchgeführten Arbeiten.

Es sind während des Krieges folgende Publikationen von mir erschienen:

1) Zur Kenntnis der Bromoxyde. II.Mitteil. (Mit H.Wiele) Journal für praktische Chemie 152, 157 1939.
2) Einige neue Halogenide des Siliciums IV. Über ein Siliciumchlorid der Formel SiCl. (Mit U.Gregor) Zeitschrift f.anorgan.Chemie 241, 325, 1939.
3) Die Chemie des Siliciums. Angewandte Chemie 53, 6 1940.
4) Zur Entwicklung des Chemischen Lehrbuches. Angewandte Chemie 53, 133, 1940
5) Über die Formel des Kaolinits. Berichte der deutschen Keram. Gesellschaft 21, 144, 1940.
6) Über die biologische und therapeutische Bedeutung der Kieselsäure. (Fortschr.d.Therapie 16, 182, 1940.
7) Pyrogene Kohlenwasserstoffsynthesen im Abschreckrohr.I. (Mit D.Pflugmacher) Journal f.praktische Chem. 156, 205 1940.
8) Pyrogene Kohlenwasserstoffsynthesen im Abschreckrohr. II. (Mit D.Pflugmacher) Journal f. prakt.Chemie 158, 1 1941.
9) Beiträge zur Chemie des Germaniums XVIII. Therapeutische Versuche mit Germaniumdioxyd. (Mit H. Scholz) Berichte d.deutschen chem.Ges. 74, 1676, 1941.
10) Chemisches Praktikum für Mediziner (Leipzig, Barth) 1941.
11) Die Chemie des Germaniums mit besonderer Berücksichtigung der Beziehungen zu seinen Nachbarelementen. Angewandte Chemie 55, 43, 1942.
12) Einige neue Halogenide des Siliciums. V. Über die Siliciumjodide. (Mit A.Pflugmacher). Berichte der deutschen chem.Ges. 75, 1062, 1942.
13) Kohlenstoff und Silicium, eine vergleichende Betrachtung. Schriften Königsberger Gelehrten-Ges. Naturw. Kl. 18, 5, 1942
14) Pyrogene Kohlenwasserstoffsynthesen III. Journal f. prakt. Chemie 161, 137, 1942.

CONFIDENTIAL

202711 6



CONFIDENTIAL

15) Beiträge zur Chemie des Germaniums XIX. Über die Polymorphie des Germaniumdioxyds. (Mit E.Haschke) Zeitschr.f.anorg.Chemie 252, 170, 1943
16) Die pyrogene Synthese aromatischer Kohlenwasserstoffe. Berichte d.deutschen Chem.Ges. 75, 2012, 1943.
17) Pyrogene Kohlenwasserstoffsynthesen. IV. Die Oxydation des Äthylens. Berichte d.deutsch.chem.Ges. 76, 1944.
18) Pyrogene Kohlenwasserstoffsynthesen. V. Synthese des Propargylaldehyds. (Mit G.Bessel) Berichte d.deutschen Chem.Ges. 76, 1944.
19) Über die Verwandtschaft von Silicium- und Kohlenstoffchemie. Die Chemie 56, 256, 1943.
20) Einige neue Halogenide des Siliciums. VI.Mitteilung. Formel und Konstitution eines Silicosebasinsäure-Derivates. (Mit Chr. Danders) Zeitschr.f.anorg.Chemie. (in Druck) 1944/45.

Der wesentliche Inhalt der wichtigeren dieser Arbeiten ist folgender:

Zu 1). Das von mir 1937 entdeckte Bromoxyd BrO_2 zerfällt bei Erwärmung unter Disproportionierung in zwei neue Oxyde, von denen das eine braun gefärbte isoliert und als Brommonoxyd Br_2O festgestellt wird. Die Eigenschaften dieses neuen einfachsten Bromoxyds werden studiert.

Zu 2): Bei der Vercrackung des 1937 von mir entdeckten hohen Siliciumchlorids $Si_{10}Cl_{22}$ unter Normaldruck bei 300° entsteht ein fester gelber Rückstand, der als Siliciummonochlorid SiCl erkannt wird. Es ist ein polymerer hochmolekularer Stoff, amorph und unlöslich in allen Lösungsmitteln. Beim Erwärmen auf 180° macht er eine reversible Farbänderung nach orangerot durch. Er wird als langkettige Verbindung mit alternierenden Doppelbindungen aufgefasst. Dementsprechend zerfällt er bei Hydrolyse und Ammonolyse unter Kettensprung in Abkömmlinge mit 6 und 8 Si-atomen, z.B. mit NH_3 in $Si_6(NH)_2(NH_2)_6$.

Zu 3): Eine Zusammenfassung meiner über 25 Jahre sich erstreckenden Arbeiten auf dem Gebiete der Siliciumchemie.

Zu 7), 8), 14), 16): Die Erfolge mit dem Abschreckrohr in der Siliciumchemie führen zu Versuchen auf organischem Gebiet.

CONFIDENTIAL

Figure D.427: During the war, Königsberg had a large staff of inorganic chemists with world-class expertise in methods that would have been useful for reprocessing irradiated fuel from fission reactors. After the war, many of those chemists were interrogated by at least two teams from the U.S. Alsos Mission [AFHRA folder 170.2279C-1 7 SEP 1945; AFHRA B1763 frames 0004–0034].

8. A possible fission reactor at I.G. Farben Leverkusen

Horace K. Calvert to Francis J. Smith. 29 January 1945. Subject: I.G. Farben Plant, LEVERKUSEN. [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-3 GERMANY: US Wartime Positive Int. (Nov. 44–June 45)]

29 January 1945

Subject: I.G. Farben Plant, LEVERKUSEN

To: Major Francis J. Smith
Room 5119, New War Dept. Bldg., Washington, D.C.

1. The following information has been extracted from a PW report dated 11 January 1945:

> "At the LEVERKUSEN I G Farben Works, PW learned through an uncle, who is a director, that a special department has been installed in concrete structures like pill-boxes, to which access is gained only through special passes, even high-ranking officers being refused admission under a special order issued 18 Nov by factory police. There is heavy A.A. defence of all calibers, and the general belief is that experiments are being made with special weapons of some kind."

2. The PW is Obergefreiter, captured between Bastogne and Longvilly 30 December 1944. He was serving as a messenger for the 7th Co., III Battalion, 31st Regt, 167th Volksgrenadier Div. 18. Oct 44 his home in Bonn was bombed out, and he applied for 30 days' leave. During November he made a trip through most of southern Germany to find a place to resettle his family.

3. There is enclosed herewith three interpretation reports covering I.G. Farben, Leverkusen. As heavy concrete constructions are characteristic of some phases of our project, it is believed that these interpretation reports and photos should be made available to technicians available to your office for their interpretation as being of interest to us.

For the Military Attaché:

H. K. CALVERT
Major, F.A.
Assistant to the Military Attaché.

Incls. 3 reports:
No. D.251; D.918R; D.643(R)

[See document photo on p. 3935.

There was a highly secret, heavy concrete installation at the I.G. Farben Leverkusen plant that the Manhattan Project's Foreign Intelligence Unit believed could be a fission reactor. (Alternatively, it might have been a uranium enrichment facility.) It is known that I.G. Farben Leverkusen was doing extensive work involving uranium hexafluoride throughout the war, and that other I.G. Farben facilities were producing many other potentially nuclear-related materials.

Where are all the detailed reports on this interrogation, any other wartime intelligence on this site, and postwar inspections of this site and interrogations of personnel who worked there?]

9. A possible fission reactor at Bodenbach/Krizik-Werke/Weser-Werke/Podmokly

[Several interrelated facilities in this area went by various names. There is a great deal of evidence that these facilities were doing nuclear work, including building particle accelerators (pp. 3979–4022). Currently there is a smaller yet intriguing set of evidence that these facilities possessed or were working on a fission reactor.]

Joint Intelligence Committee. Exploitation of German Scientists and Technicians. 5 January 1946. J.I.C. 317/10. [NARA RG 218, Entry UD-1, Box 475, Folder CCS 471.9... (5-1-45)... Sec. 3]

APPENDIX "C"

U.S.S.R. EXPLOITATION OF GERMAN SCIENTISTS AND TECHNICIANS

1. Interrogation of qualified German personnel both in Europe and this country, as well as numerous intelligence reports, all indicate that long-range exploitation of German scientific and technical personnel and facilities is both thorough and intelligent throughout the Soviet Zone. Briefly the situation in some fields is:

a. Atomic research: The 7 top men working on atomic research in Germany were: Prof. HEISENBERG, Prof. HERTZ, Baron VON ARDENNE, Prof. BOTHE, Prof. STETTER, Dr. GERLACH, and Prof. BEWILOGUA. Of these HERTZ, BEWILOGUA, VON ARDENNE, and BOTHE (Formerly in the U.S. Zone) are now working for the U.S.S.R. with many of their assistants. Practically the entire staff of the German "URANMOTOR" Project at KRIZIK in Czechoslovakia under Prof. HUETTIG is working for the U.S.S.R., so are large numbers of the staff of the Kaiser Wilhelm Institute connected with atomic research.

[See the document photos on pp. 3993–3996.]

T. M. Odarenko. 26 October 1945. Problem of Displaced Scientists Now Residing in the American Zone of Austria. [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-2 GERMANY: Personnel (Jan 45–Dec 45)]

6. Among these evacuees there is a very large group of capable scientists who worked in the field of nuclear physics and chemistry and who have been carrying this work with such facilities as they have been able to assemble. There are two (or possibly more) institutes which were directly involved before the end of the war in a secret German project called "Uranmotor" whose purpose was to split uran atoms in order to obtain a powerful source of intra-atomic energy. It is apparent that the end result of this work is a method of obtaining an explosive release of atomic energy, or atomic bomb. The two groups definitely identified with the Uranmotor project are Kaiser Wilhelm Institute and Institut für Neutronenforschung. Professor Stetter, Professor Mattauch, Professor Thirring, Dr. Schintlmeister, Dr. Jentschke, Dr. Ortner, Dr. Ing. F. Focke are some of the names reported to the undersigned to have been directly involved in the project and capable of completing it as soon as the opportunity will present itself.

[See document photos on pp. 4790–4795. Franz Focke, mentioned in the above document, was a longtime technician at Bodenbach/Krizik. The following two documents report on some of his postwar interrogations.]

Headquarters, United States Forces in Austria. 10 October 1949. Focke, Franz—Atomic Energy Scientist. [NARA RG 319, Entry A1-134B, Box ??, Folder XE065437 Focke, Franz]

Subject claims that he started research work in the atomic energy field in 1920, using the laboratories of the Krizik Chaudoir firm at Bodenbach, CSR. Subject also stated that the main purpose of his work was to convert uranium ore and radium combinations to electrical energy and to accelerate the decomposition of uranium and radium. Subject also stated that in 1945 he had in his possession approximately 4 pounds of uranium value at 20,000 Marks.

[See the document photo on p. 3985.]

Headquarters, United States Forces in Austria. 10 October 1949. Focke, Franz—Atomic Energy Specialist. [NARA RG 319, Entry A1-134B, Box ??, Folder XE065437 Focke, Franz]

Subject is a very interesting case and one who requires careful evaluation. He has a better than average knowledge of atomic energy and it would seem impossible to class him as peculiar or a crackpot. He has written his letters in such a manner that he has covered the entire field of nuclear research and experimentation, some sections of which have high intelligence value. [...]

His statement about possession of 4 pounds of uranium valued at 20,000 Marks is also suspicious. Also, there was once a report of an atomic pile operated by Russians at Bodenbach, CSR, which we now believe to be false.

[See the document photo on p. 3986.

According to Franz Focke, a longtime technician at Bodenbach/Krizik, nuclear research began there no later than 1920, continued through World War II, and resulted in a fission reactor there that fell under Soviet control after the war. The interrogators were skeptical about the reactor claim, but it is consistent with the large amount of other nuclear-related work at that same site (pp. 3979–4022).

The famous German film director Fritz Lang moved to the United States in 1933 and continued making movies there. In 1946, Lang directed the film *Cloak and Dagger* for the Warner Bros. studio. *Cloak and Dagger* presented a fictionalized story of how during World War II, OSS and European resistance members investigated and combatted the German nuclear weapons program. As scripted and filmed, the movie ended with a visually impressive and highly expensive sequence in which U.S. forces bomb several German nuclear weapons factories and visit another one in person. However, before the film was released, that entire sequence was censored and apparently destroyed.

Although *Cloak and Dagger* was fiction, Lang's story descriptions and the script versions included an extraordinary number of details that agree stunningly well with real information about the German nuclear weapons program which was not publicly known in late 1945/early 1946 when the film was being written and shot (pp. 5076–5081). Among other details, in early versions of the script the final German nuclear weapons facility that was stormed by U.S. forces was a breeder fission reactor at Bodenbach.]

10. Other possible fission reactors

[In addition to the known or reported reactors at the sites already mentioned, there may have been other fission reactors within German-controlled territory during the war. The following pages present some of the evidence suggesting the existence of other reactors.]

Leo Szilard to Karl Taylor Compton. 1 June 1942 [NARA RG 227, Microfilm M1392, Bush-Conant File Relating to the Development of the Atomic Bomb, https://downloads.paperlessarchives.com, p. 6148]. See document photo on p. 3939.

I wonder if it would be worth trying to find out something about what the Germans are doing. In this respect we can use as a starting point the following fact: in September last year [1941], Dr. Marshall told me the following—a son of Dessauer who arrived from Switzerland told Marshall that according to his information the Germans got a chain reaction going. Dessauer used to be a professor in Germany in Frankfort and he emigrated during the Hitler regime to Switzerland. One of his sons is a physicist who has been in this country for a number of years and who is at present at the University of Rochester. The other son who came to this country more recently is not a physicist and it is therefore doubtful whether by questioning him one can obtain any useful information.

[Was this only a report of one of the subcritical fission experiments, or did a German fission reactor at an unknown site achieve criticality by 1941–1942?]

IN RE:

I wonder if it would be worth trying to find out something about what the Germans are doing. In this respect we can use as a starting point the following fact: in September last year, Dr. Marshall told me the following - a son of Dessauer who arrived from Switzerland told Marshall that according to his information the Germans got a chain reaction going. Dessauer used to be a professor in Germany in Frankfort and he emigrated during the Hitler regime to Switzerland. One of his sons is a physicist who has been in this country for a number of years and who is at present at the University of Rochester. The other son who came to this country more recently is not a physicist and it is therefore doubtful whether by questioning him one can obtain any useful information.

I wonder if the following procedure might not be good: to give a physicist who is not connected with work on uranium, diplomatic status and send him over to Switzerland. By establishing contact with Dessauer and other physicists who frequently visit German scientific meetings, it should be possible to pick up some useful information. I was thinking as a possible candidate for such a mission of K. C. Cole, who is a physicist but is Professor of Physiology in the Columbia University Medical School.

It might be argued, of course, that if we are going full speed ahead anyway, there is not much point in trying to find out what the Germans are doing since there is no possibility of any defenses anyway.

KT

Dictated but not read by Mr. Szilard. He had to catch a train.

Was this only a report of one of the subcritical fission experiments, or did a German fission reactor at an unknown site achieve criticality by 1941–1942?

Gerhard Dessauer (University of Rochester Department of Physics) to Leo Szilard. 6 July 1942 [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-1 GERMANY: US Wartime Positive Int. (July 42–June 44)]. See document photo on p. 3941.

Upon the request of V. Weisskopf I am quoting a few lines of a letter I received from my father on July 1st.

My father, Dr. E. Dessauer, teaches Physics at the University of Fribourg (Switzerland). Dr. W. Gentner's—the German nuclear physicist's—parents-in-law, Dr. and Mrs. P. Pfaehler were very close friends of my father. The Pfaehlers died early this year so that Dr. and Mrs. Gentner will no longer have the occasional permission by the German Government to go to Switzerland.

As Gentner did his Ph.D. work under my father at Frankfurt (Germany) (where he also met his wife) he used to visit my parents rather regularly whenever he came to Switzerland.

In his letter of April 1st (which I received on July 1st) my father mentions that he had a long talk with Gentner in Bern before saying good-bye for an indefinite time. Later on in the letter my father writes:

> "Ich erfuhr, dass die Kettenreaktion des Uranisotops jetzt gelingt. Sie ist nicht explosiv, aber die Aussicht auf technische Verwertung besteht nunmehr."

> ["I learned that the chain reaction of the uranium isotope is now successful. It is not explosive, but there is now the prospect of technical utilization."]

There is no explicit connection of this statement with the conversations with Gentner in the letter, but he may have heard that from Gentner. [...]

Gerhard Dessauer

July 6, 1942

Dr. Leo Szilard
Metallurgical Laboratory
The University of Chicago
Chicago, Ill.

Dear Dr. Szilard:

Upon the request of V. Weisskopf I am quoting a few lines of a letter I received from my father on July 1st.

My father, Dr. E. Dessauer, teaches Physics at the University of Fribourg (Switzerland). Dr. W. Gentner's - the German nuclear physicist's - parents-in-law, Dr. and Mrs. P. Pfaehler were very close friends of my father. The Pfaehlers died early this year so that Dr. and Mrs. Gentner will no longer have the occasional permission by the German Government to go to Switzerland.

As Gentner did his Ph.D. work under my father at Frankfurt (Germany) (where he also met his wife) he used to visit my parents rather regularly whenever he came to Switzerland.

In his letter of April 1st (which I received on July 1st) my father mentions that he had a long talk with Gentner in Bern before saying good-bye for an indefinity time. Later on in the letter my father writes:

> "Ich erfuhr, dass die Kettenreaktion des Uranisotops jetzt gelingt. Sie ist nicht explosiv, aber die Aussicht auf technische Verwetung besteht nunmehr."

There is no explicite connection of this statement with the conversations with Gentner in the letter, but he may have heard that from Gentner. Again, as my father does not know much about nuclear physics, his communication may be based on a misunderstanding. In any case, I was somewhat surprised to find such news in a letter from Europe to the U.S.A. these days.

Whether this is of any value or not, Weisskopf and I felt that it should be reported to some of you defense people.

Very sincerely yours,
/s/ Gerhard Dessauer

3 April 1944

Activities from 13 March to 31 March 1944

1. Received British cable containing important information.

2. Activities of the Italian Alsos Mission completed. Report of the Mission was distributed. The continuance of the Alsos Mission on a broader basis was recommended in a draft of a memorandum to the Chief of Staff and presented to Colonel Nicholas for appropriate action through G-2.

Lt. Col. Pash was transferred to the Manhattan District.

3. Orders and transportation to UK were arranged for Calvert, Traynor and Peterson.

4. Admiral Purnell asked Walter to advise him if a trip to this country for indoctrination would be feasible at this time.

5. Severance from the project while in a combat Theater was arranged for Dr. Harrison of MIT.

6. OSS received important cables on developments in Norway and scientific activities in Germany. Their Italian organization undertook the Shark Mission.for the procurement of important Italian scientific personnel.

7. The review of scientific literature on diffusion by Dr. Cohen of Columbia was initiated.

8. Mr. Chapin reported successful detection experiments and requested aircraft study.

9. UMDC surveys into Portuguese, Spanish Madagascar sources were discussed with Major Guarin.

10. Positive intelligence summary report was presented on 7 March 1944.

11. Pictures were obtained of pre-war Joachimstahl and the British undertook the procurement of current photographs in the Joachimstahl and Schoenficht areas.

SECRET

12. Installments of rare metals report were received from the FEA.

13 The New Developments Division briefed Parsons, Fisk and Pash on cross bow problem.

14. As a result of the evaluation of an informant interviewed in Italy by the Alsos Mission, Major Gaspari of the Royal Italian Air Force has been requested by the National Advisory Committee for Aeronautics who desire him for further questioning.

15. Old intelligence information is available in Dr. Conant's files was presented by Dr. Wensel in review.

16. Enemy development possibilities were discussed with Dr. Urey.

Figure D.431: In March 1944, Leslie Groves's Foreign Intelligence Unit reported "successful detection experiments" of German radioactivity (most likely from an operating fission reactor) and requested aerial surveillance photos of that German site. Where are the detailed reports? [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]

Frederic A. C. Wardenburg and James A. Lane. 5 April 1945. SUBJECT: Interrogation of Dr. Kohl, Works Manager of Degussa Plant No. 2, Frankfurt. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA (1943–June 1946)]

1. Dr. Kohl was interrogated in Frankfurt on 3 April 1945 by J. A. Lane and F. A. C. Wardenburg. Dr. Kessler, one of his assistants and also his secretary were present during the interrogation and were called on from time to time by Dr. Kohl on matters of detail.

2. Uranium metal, which was known by the code name of "Spezialmetall", was manufactured at the Degussa, Frankfurt plant. According to Dr. Kohl the material was required by the Reichsforschungsrat and all administrative matters were handled by Auergesellschaft in Oranienburg directly with RFR. Degussa acted as a sub-contractor for Auer. All deliveries from the Frankfurt plant were made either to Auer or to the RFR at Berlin-Dahlem. The use of the material was secret. Dr. Kohl believed that it had something to do with experiments in atomic physics. The material was manufactured in a purity of 98 to 99 percent from ammonium uranate which was converted to the oxide U_3O_8. The ammonium uranate was secured either from the Joachimsthal mines or from Katanga (Union Minière du Haut Katanga).

3. Earlier, metallic uranium was mixed with coal dust (carbon?) and with Tragacanth gum as a binding material and pressed into blocks, approximately 50% by weight of coal and uranium. The blocks were approximately 5 cm x 5 cm x 6 cm. About five tons as metallic uranium in total were delivered in this form. The material is now delivered as powdered metallic uranium, production being between one and two tons, making a total uranium production of between six and seven tons.

4. We visited the site of the plant which had been partially destroyed. The equipment was moved in December to a location in Markbrandenburg where Dr. Kohl believed the RFR had a branch. A part of the equipment was moved to the plant of the Chemische Fabrik Grunau at Grunau near Berlin. Dr. Kohl thought it might have been moved again but he did not know the exact location, but suggested somewhere in Thüringen as a probable evacuation address.

[See document photo on p. 3945.

This Degussa plant produced at least 10 tons of blocks containing 50% uranium and 50% graphite. No publicly known German fission reactors used such fuel blocks, so they must have been requisitioned for a graphite-moderated reactor that is not publicly known.

Even though Dr. Kohl, the works manager of the Degussa plant, aided by his staff, had given U.S. investigators a detailed description of the 10 tons of 50% uranium–50% carbon 5x5x6 cm blocks that had been produced there, the technical director Dr. Baerwind was curiously quick to deny and deflect the investigators' questions when he was separately asked about those blocks. See pp. 3946–3947.]

SUBJECT: Interrogation of Dr. Kohl, Works Manager of Degussa Plant No. 2, Frankfurt.

6

1. Dr. Kohl was interrogated in Frankfurt on 3 April 1945 by J. A. Lane and F. A. C. Wardenburg. Dr. Kessler, one of his assistants and also his secretary were present during the interrogation and were called on from time to time by Dr. Kohl on matters of detail.

2. Uranium metal, which was known by the code name of "Spezialmetall", was manufactured at the Degussa, Frankfurt plant. According to Dr. Kohl the material was required by the Reichsforschungsrat and all administrative matters were handled by Auer Gesellschaft in Oranienburg directly with RFR. Degussa acted as a sub-contractor for Auer. All deliveries from the Frankfurt plant were made either to Auer or to the RFR at Berlin-Dahlem. The use of the material was secret. Dr. Kohl believed that it had something to do with experiments in atomic physics. The material was manufactured in a purity of 98 to 99 percent from ammonium uranate which was converted to the oxide U_3O_8. The ammonium uranate was secured either from the Joachimstahl mines or from Katanga (Union Miniere du Haut katanga).

3. Earlier, metallic uranium was mixed with coal dust (carbon?) and with Tragacanth gum as a binding material and pressed into blocks, approximately 50% by weight of coal and uranium. The blocks were approximately 5 cm x 5 cm x 6 cm. About five tons as metallic uranium in total were delivered in this form. The material is now delivered as powdered metallic uranium, production being between one and two tons, making a total uranium production of between six and seven tons.

4. We visited the site of the plant which had been partially destroyed. The equipment was moved in December to a location in Markbrandenburg where Dr. Kohl believed the RFR had a branch. A part of the equipment was moved to the plant of the Chemische Fabrik Grunau at Grunau near Berlin. Dr. Kohl thought it might have been moved again but he did not know the exact location, but suggested somewhere in Thuringen as a probable evacuation address.

5. Dr. Kohl was emphatic in his assertion that no deliveries of uranium were made to the I. G. Farben Industrie.

6. Before the war, approximately three tons per month of sodium uranate were used in the ceramic color business. Since 1940 the use of uranium for this purpose has been prohibited and so far as Dr. Kohl knows, none is consumed except for the scientific experiments. Approximately three tons of ammonium uranate were shipped with the equipment to Grunau.

7. The management of Degussa evacuated in March, 1944 to Waechtersbach.

5 April 1945.

SUBJECT: Interrogation of Dr. Baerwind, Technical Director - DEGUSSA.

Dr. Baerwind who is a director of Degussa in charge of technical matters and also in direct charge of the precious and rare metals department was interrogated by J. A. Lane and F. A. C. Wardenburg in Frankfurt on 3 April 1945.

1. We told Dr. Baerwind that we had learned of the existance of a metal known as "Spezialmetall" and that we were interested in discovering what it was and for what purposes it was used. He told us quite frankly that it was uranium metal, that the use was secret but that he believed it was used by a group of professors whose names he did not know for scientific research connected with changes in the atom. He referred to Prof. Hahn as one of the leading scientists in this field and stated that scientists in the United States had done work on a much larger scale. He believed the work to be conducted in Berlin by the KWI and perhaps in other locations with which he was not familiar. All contact with the group of scientists was conducted by Auer, and Degussa did not deal with them directly. Baerwind himself is a member of the Supervisory Board of Auer and Herrman Schlosser, Managing Director of Degussa, is Chairman of this board. Nevertheless, he was not familiar with the dealings between Auer and the group of scientists. When first asked how much uranium had been produced in total, he said between four and six tons, but when later questioned further, he said the very outside figure in four years would be eight tons.

2. According to Dr. Baerwind, U308 is manufactured by Auer from ammonium uranate and the U308 was reduced by Degussa with calcium to form the metal. The powder is fused in Degussit molds (refractory material) and emerges in slabs about ½"x4"x4" and also in slabs of approximately twice this thickness. The development of a vacuum oven was necessary before the material could be fused into slabs. The equipment has now been moved to the Chemische Fabrik Grunau at Granau,

Figure D.433: Dr. Kohl, the works manager of the Degussa plant, aided by his staff, had given U.S. investigators a detailed description of the 10 tons of 50% uranium–50% carbon 5x5x6 cm blocks that had been produced there, but the technical director Dr. Baerwind was curiously quick to deny and deflect when asked about those blocks [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA (1943–June 1946)].

TOP SECRET

near Berlin. He stated definitely, as Dr. Kohler had done, that Degussa was the only manufacturer of uranium metal in Germany and therefore, the Frankfurt plant production was the total production in Germany.

3. He said that in his opinion, the material although handled under secrecy could have nothing to do with military weapons because the quantities involved were so small.

4. Degussa produced five to six tons per year of Beryllium metal but most of it was sent to Heraus for the manufacture of beryllium copper alloys but that a small amount had been sent to the RFR for experiments with radioactive materials.

5. The purity of the uranium metal was required to be less than ½ of 1% of other metals but because of the inclusion of some oxygen, the total uranium content was between 98 and 99%.

6. Dr. Baerwind stated definitely that the powder had never been mixed with coal which was contrary to Dr. Kohl's statement but he said that the production was of such relative unimportance, requiring one or two men per shift, that he was not familiar with the technical details. He also thought that Dr. Kohl was not familiar with technical details and suggested that Dr. Voelkel would be the man to talk to, but unfortunately he was in Berlin. We asked Dr. Baerwind to describe what he thought was done with the metal and he said he was under the impression it was put together to give some form of radiation and a large amount of it was needed to form a single mass. He referred to the beryllium deliveries in the same connection and assumed that a very light metal and a very heavy metal were used in this way for comparative purposes.

7. Dr. Baerwind can be reached at the Stierstadt plant of Degussa which is near Oberursel, on the outskirts of Frankfurt.

g. A Mr. Richard P. FISCHER representing the OCE, War Department, has completed an investigation of German supplies of uranium during the war. A copy of his report was obtained by this office and some of the material contained therein is considered objectionable. Major SMITH'S Office was notified and this office suggested that Col. MEIDLING, the present custodian of the report in ETO, be directed by OCE to forward the report to OCE to be censored by General GROVES' Office.

Alfred L. Busch et al. June 1994. Memorial to Richard Philip Fischer 1910–1991. *Memorials* Vol. 25, Geological Society of America.
https://rock.geosociety.org/net/documents/gsa/memorials/v25/Fischer-RP.pdf

[...] Throughout the war years (1941–1945) he was in charge of the Colorado Plateau vanadium project, with greater emphasis after May 1944 on the uranium component at the request of the Manhattan Engineering District (better known as the Manhattan Project). Earlier, in 1942, he had reported on the world's uranium resources for the Office of Scientific Research and Development. At one stage of his wartime studies of uranium, he was prohibited by the government, overly intent on security, from borrowing from the library one of his own publications! The Colorado Plateau work was interrupted in 1945 by an assignment in Germany for the Intelligence Section of the Army Corps of Engineers, European Theater of Operations (ETO), to study German ore supplies and the use of vanadium, uranium, niobium, lead, and zinc; the engineering geology of underground bunkers and factories; and, in addition, military geology functions and personnel. [...]

[Richard P. Fischer was a highly respected expert on the mining of uranium and other heavy metals, with a Ph.D. in geology from Princeton and a long career with the U.S. Geological Survey. At the end of World War II, he was hired by the U.S. War Department specifically to survey the status of German uranium supplies and underground bunkers and factories, and to write a report on his findings. Leslie Groves personally censored his report, so his results were never released. Fischer was even denied access to his own reports that he had written. For more information, see pp. 3949–3951.]

Richard P. Fischer. June 1945. Report on German Supplies of Uranium-Bearing Raw Materials. Draft CIOS report. [NARA RG 77, Entry UD-22A, Box 163, Folder Australia] See document photo on p. 3950.

About 50 to 60 tons of strongly radioactive “tarnsand” was delivered to the German Army, according to Mr. Futterkneck of the firm Geophysikalische Gerätebau. The “tarnsand” was used to activate artificially the soil covering non-metallic mines, so that presence of a mine could be indicated with a mine detector sensitive to radioactivity. The detector and its use has been reported on by Mr. C. A. Hachemeister, Civ., OCE, and therefore will not be discussed in this report, but the nature of the “tarnsand” is of interest. The “tarnsand” was said to have been supplied by Auergesellschaft, to be the residue from the extraction of radium from pitchblende ore, and to have the same radioactivity as ore containing about 10 percent pitchblende. Preliminary tests made by R. P. Fischer show that the “tarnsand” has the equivalent radioactivity of ore containing 5 to 10 percent uranium in equilibrium with its disintegration products, confirming the last part of the above statement. Until the “tarnsand” is analyzed chemically, its exact nature cannot be determined. It is unlikely, however, that the “tarnsand” is actually the residue from the extraction of radium from ore, as reported, for such material should be only slightly radioactive. It also seems unlikely that the “tarnsand” is prepared directly from St. Joachimsthal crude ore, even though its radioactivity is about the same as the ore, for it is believed that the German requirements for radium and uranium were too important to use and dissipate the ore in the form of “tarnsand”. More likely the “tarnsand” was prepared from material in which the radioactivity has been artificially induced. On the other hand, it is possible that the radioactivity of the “tarnsand” is derived from the thorium series rather than from the uranium series or from artificially induced radioactivity, for it is reported that Auergesellschaft treated monazite sands for rare earths and thus would obtain thorium as a by-product. The problem is of interest mainly in attempting to account for the quantity of radioactive materials available to Germany.

[Dr. Richard P. Fischer, a U.S. Geological Survey expert on radioactive minerals, concluded that wartime Germany likely had a working fission reactor capable of irradiating at least 50–60 tons of “tarnsand.” Fischer’s report was promptly confiscated by the office of Leslie Groves and never published.

For more information, see p. 3948.

Where is the 1948 analysis of “tarnsand” that is mentioned in the left margin of the document on p. 3950?]

Geology of uranium-bearing deposits.-- Uranium-bearing minerals are widely distributed in the crust of the earth, but deposits containing a sufficient concentration of uranium to be worked with a profit are few. The deposits of greatest commercial importance consist of pitchblende associated with sulphides of silver, cobalt, and nickel, such as the deposits in Belgian Congo, in northern Canada, and near St. Joachimsthal, Bohemia. The carnotite deposits of Colorado and Utah have yielded significant amounts of uranium and vanadium ore, and somewhat similar deposits occur in

Dear George:

Mr. Parks, a geologist for the Engineers who has recently returned to the States, was interviewed and he stated that there was sizeable pile of material that originally came from the Belgian-Congo now at Hamburg. The material was being used by the KWI and even though we don't know his interpretation of a sizeable pile, we believe it would be worthwhile looking into.

Parks also stated that Mr. Richard P. Fischer would in all probability know something about this material. You will recall we wrote you a letter concerning Fischer as a possible contact.

It is suggested that you take a look at this material and a note concerning the importance of it would be appreciated.

FRANCIS J. SMITH,
Major, Corps of Engineers.

D.6 Electronuclear Systems for Breeding Pu-239 and/or U-233

[Walther Bothe (German, 1891–1957), Walter Dällenbach (Swiss, 1892–1990), Max Steenbeck (German, 1904–1981), Rolf Wideröe (Norwegian but studied and worked in Germany, 1902–1996), and many others pioneered particle accelerators from their beginnings in the 1920s through World War II (p. 3020).

The following documents show that in German-controlled areas, a considerable number of high-energy particle accelerators were produced, and in some cases used, as high priorities during the war. Purely scientific research would not have been sufficient justification for all of the funding, labor, and materials that went into these accelerators when war needs and shortages were so dire. As discussed in Appendix C (p. 3020), one motivation for some of the accelerator work was apparently the development of directed energy weapons, yet that would only account for some small fraction of the accelerators that were produced. Most of the accelerators appear to have been closely linked with the German nuclear weapons program.

There are at least three possible applications for accelerators in a nuclear weapons program:

1. Measuring fundamental nuclear properties that are relevant to designing nuclear reactors and bombs. One or two modest accelerators would have been sufficient for that purpose, and Germany already had access to the Joliot-Curie cyclotron in Paris for such measurements.

2. Using a compact ∼6 MeV (million electron volt) betatron to produce free neutrons in a fission bomb at the optimal time during implosion, as discussed on pp. 4492 and 5159.

3. Using a number of accelerators in parallel to produce enough neutrons without a fission reactor in order to breed militarily useful amounts of fissile plutonium-239 from uranium-238, or fissile uranium-233 from thorium-232. This process is called electronuclear breeding. Fissile neptunium-237 [Sanchez et al. 2008] could also have been bred via particle accelerators (e.g., by knocking a neutron out of U-238), although it probably would have been more difficult to produce in quantity than Pu-239 or U-233 [Benedict et al. 1981].

The sheer number and high priority of the accelerators covered in the following documents suggests that many of those accelerators were intended for electronuclear breeding. There is some evidence that such systems may have been operational during the war.

For information on the physics of electronuclear breeding, see p. 5133.

In addition to the documents in this section and in Appendix C, an extremely important piece of evidence is Georgy Flerov's story about multiple cyclotrons in a highly secret underground SS/Reichspost installation in Silesia on pp. 4504–4510.]

SUBJ: Transmission of Report

TO : Lt. Col. Richard H. Free

1. The information furnished below may be of interest regarding Dr. Willibald Jentschke.

2. Subject was born in Vienna 6 December 1911. He took his Ph.D. at the University of Vienna in 1935 in nuclear physics. Married and with one child, he now resides at 14 Kopp Strasse, Vienna XVI, French Zone. In 1938 he became unpaid scientific researcher under a Prof. SCHWEIDLER, head of the Physics Institute, University of Vienna, and worked on measurements of ionizations and of the mass of the neutron. Later, he became the paid assistant of Prof. STETTER, head of Physics Institute #2, University of Vienna. Following anschluss, he applied for membership in the NSDAP but was finally rejected in 1943. This old application has caused an investigation to be started concerning his present government job. While still at the University of Vienna, subject also worked under Prof. HAHN on the uranium atom. His work consisted of research on the exact measurements of the energy released by the fission of U_{235} and U_{238}, also by the bombardment of thorium and ionium.

3. In 1945, as the Red Army drew near, much equipment and material was transferred to Thummersbach, and subject remained to guard another temporary installation at Schwallenbach. While there, he worked on the loss of energy occasioned by the treatment of uranium atoms with high frequency electrical currents.

4. While away from Vienna, subject knew of no Austrian scientists who went into Soviet employ. SCHINTELMEISTER's acceptance occurred after the return to Vienna which, for subject, was on 28 March 1946. Subject was also offered a job, but declined. A trip to Moscow was also offered, and was declined as well.

* * * * *

C. December 15:

German research concerning the decomposition of atoms.

The famous "Forschungsstelle K" which was working on the solution of this question has been transferred from Berlin to Sigmaringen with a cyclotron bearing the number 7. The laboratories are installed in the hill on which the castle of Sigmaringen stands. Half a dozen famous physicists are working there under the orders of professor Weiszaecker (son of the Ambassador to the Vatican) and professor Neysenberg, formerly of Leipzig. The latter, who is a member of the Kaiser Wilhelm Institute, is considered one of the most famous specialists in the world. Half-way between Sigmaringen and Reutlingen is the little village of Hechingen where there is a second group of specialists with another cyclotron. This is probably the group which until recently worked in Strassburg.

The Forschungsstelle 2 which was hitherto in Florisdorf near Vienna has been transferred to Tegernsee.

Caperton B. Horsley. 22 June 1945. CIOS ER 129. ***Siemens-Reiniger-Werke A.G. A. Erlangen. B. Rudolstadt.***

A. [Erlangen] 1. This plant designs and manufactures X-ray apparatus and other electro-medical equipment. It is the largest plant of its kind in Germany. It recently had about 3,000 employees. During the last several years it has also manufactured, but not designed, some components for aircraft radio, instrument and control equipment.

2. The following men were interviewed: [...]

All of the above men were very cooperative.

3. A considerable amount of information was obtained regarding:

A. Their latest developments in X-ray equipment, one and six meter high-frequency medical equipment, metal locators, shock therapy equipment, supersonic [ultrasonic] therapy equipment, and Betatrons.

B. The location and general description of the most important Betatron, Cyclotron, Van de Graaff generator, and mass spectrograph installations in Germany and territory that has been occupied by the Germans.

C. Recent German research in atomic physics; particularly regarding isotope separation.

D. The possible present location of a number of German physicists and directors of research programs. [...]

B. [Rudolstadt] 1. This plant manufactured a complete line of X-ray tubes, and valve tubes for use in X-ray equipment. They have also recently manufactured amplifier tubes for use in telephone systems, surge arresting tubes for protecting communications lines, several types of small gas filled detectors for use in "timing" circuits for bombs and shells, and fluoroscopic and intensifying screens. [...]

3. A number of tubes were found that were superior in certain respects to tubes now being manufactured in the United States.

4. The following personnel were interviewed [...]

All of the above men were exceedingly cooperative, and a considerable amount of seemingly valuable information was obtained from them regarding:

A. The entire German X-ray industry.

B. Recent magnetron and other U.H.F. tube developments by Siemens-Halske.

C. The names and addresses of a number of physicists who have recently been doing work on isotope separation.

D. The possible location of a number of men who have been in charge of recent U.H.F. developmental and experimental work.

Caperton B. Horsley. 16 July 1945. CIOS ER 174. ***C. H. F. Müller A.G., Hamburg, Fuhsbuttel, Roentgenstrasse 24.***

This company designed and manufactured the following equipment:

a) A line of X-Ray tubes, and a number of valve tubes for X-ray equipment

b) A line of X-Ray tube housings with flexible high tension cables.

c) A small transformer and X-Ray tube head for use with dental and Army field units.

d) Certain miscellaneous X-Ray equipment items.

e) "Cascade" high voltage generators, from 900 to 2,400 Kv. for deutron acceleration.

The following equipment was manufactured, but not designed by this company:

a) "Underwater Sound Equipment" assemblies.

b) Aircraft instrument and electrical equipment components.

c) Gas filled rectifiers for communication work.

[...] In addition to the above:

a) They were about to start the production of a magnetron that had been designed by Telefunken.

b) They had designed and constructed an experimental 2 M.V. betatron.

c) Working on specifications supplied by the "MV Research Assn", at Wrist, they had constructed and delivered to Wrist a 15 M.V. betatron.

The following persons were interviewed, all of whom were cooperative:

Otto Gundermann,	Administration Manager
Dr. Werner Fehr,	Assistant Manager
Kurt Weigel,	Manager of X-Ray Tube Division
Arthur Lipphaus,	Mechanical Engineer
Alfred Kuntke,	Chief Research and Development Engineer
Adolf Hoffmann	"Construction" Engineer

The following information was obtained:

a) General information regarding their recent production figures.

b) Complete information regarding their X-Ray tube developments during the past 5 years.

c) Complete information regarding their design and construction of their "Cascade" high voltage unit.

d) Complete information regarding their patent applications since 1938.

e) Miscellaneous information regarding magnetrons, betatrons, infra-red photoelectric cells, the use of their "Cascade" units, and the activities of Dr. Ritz and Dr. Müller, both of whom were formerly connected with this company.

A number of photostats and blueprints were made of existing documents and drawings to provide the information outlined above. The only original documents removed from this plant covered miscellaneous information regarding magnetrons and betatrons.

The following production items were taken from this plant for further examination:

a) Several of their more recently developed X-Ray tubes.

b) Several high voltage rectifier tubes.

c) An end-ground industrial X-Ray tube head

d) 1 dental X-Ray tube head.

e) 1 magnetron

f) An experimental 2 M.V. betatron

g) A few miscellaneous production parts.

The total floor area of this plant is about 80,000 square feet. As of the first of this year the number of employees was about 500. The plant is in good condition and well equipped. [...]

List of Equipment, etc., Evacuated by Mr. Horsley of T.I.I.C. from 21 AG Area 1, July, 1945.

No originals except Dr. Müller's Betatron Notebooks and Misc. Magnetron Data from C.H.F. Müller.

BOX 1.

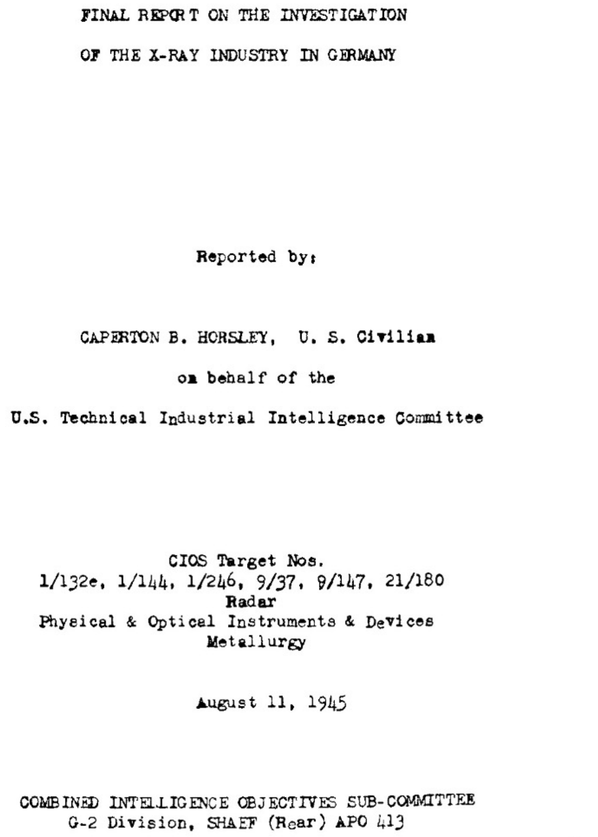
[This company was designing and manufacturing high-voltage deuterium-filled tubes for use as fusion neutron sources. It was also designing and manufacturing high-voltage betatrons. Both of those would have made excellent neutron initiators for a fission bomb. In fact, both of those neutron initiators were apparently described in Ilyichev's March 1945 intelligence report on a German fission implosion bomb design; see pp. 4485 and 5157. If these devices were mass-produced, they might have also been useful for electronuclear breeding of fission fuel.]



FINAL REPORT ON THE INVESTIGATION

OF THE X-RAY INDUSTRY IN GERMANY

1.

GENERAL:

This report is based on information obtained during an investigation of the German X-Ray industry and associated industries. This investigation started in Leipzig on May 5, 1945, and was completed in Bad Oeynhausen on June 30, 1945.

In this report, no attempt is made to describe technical developments in detail, as these matters are covered in the special reports and other documents listed in the Appendix.

TECHNICAL DEVELOPMENTS:

Vacuum Tubes:

The most apparent German developments, trends and practices pertaining to the design and construction of X-Ray tubes for X-Ray equipment may be briefly described as follows:

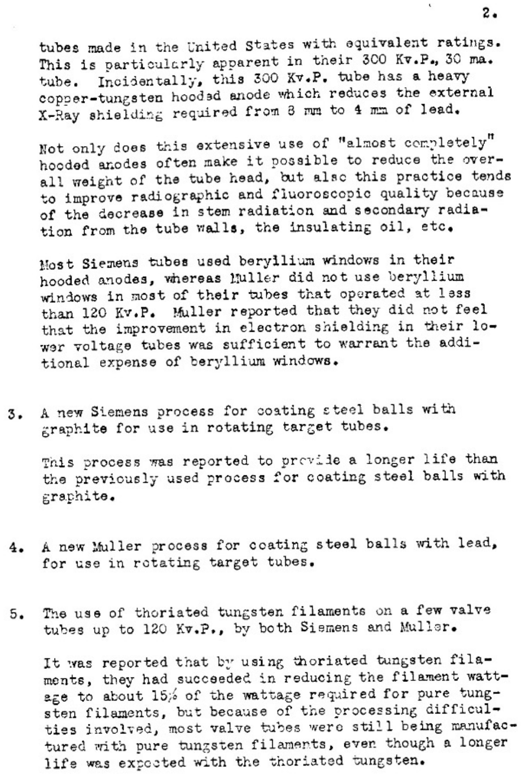
1. End ground tubes with long electron beam paths, with and without magnetic focusing, in the range of from 45 to 200 Kv.P.

   Most of the tubes used for industrial radiography or fluoroscopy were end ground, magnetically focused, and water cooled. Tubes of this type were made by Siemens, Muller, and A.E.G. The rating for most of these industrial tubes was 150 Kv.P. at from 10 to 20 ma., continuously.

   Siemens also made a line of end ground tubes in the 45 to 100 Kv.P. range for contact (orificial) therapy. These end ground therapy tubes generally had transmission targets, were water cooled, and did not require magnetic focusing.

2. Very effective use of hooded anode construction.

   By thus preventing secondary electrons from accumulating and building up a charge on the inner glass walls of the tube, and by effective construction and processing methods, Siemens has succeeded in producing some types of tubes that are appreciably smaller in size than



2.

tubes made in the United States with equivalent ratings. This is particularly apparent in their 300 Kv.P., 30 ma. tube. Incidentally, this 300 Kv.P. tube has a heavy copper-tungsten hooded anode which reduces the external X-Ray shielding required from 8 mm to 4 mm of lead.

Not only does this extensive use of "almost completely" hooded anodes often make it possible to reduce the overall weight of the tube head, but also this practice tends to improve radiographic and fluoroscopic quality because of the decrease in stem radiation and secondary radiation from the tube walls, the insulating oil, etc.

Most Siemens tubes used beryllium windows in their hooded anodes, whereas Muller did not use beryllium windows in most of their tubes that operated at less than 120 Kv.P. Muller reported that they did not feel that the improvement in electron shielding in their lower voltage tubes was sufficient to warrant the additional expense of beryllium windows.

3. A new Siemens process for coating steel balls with graphite for use in rotating target tubes.

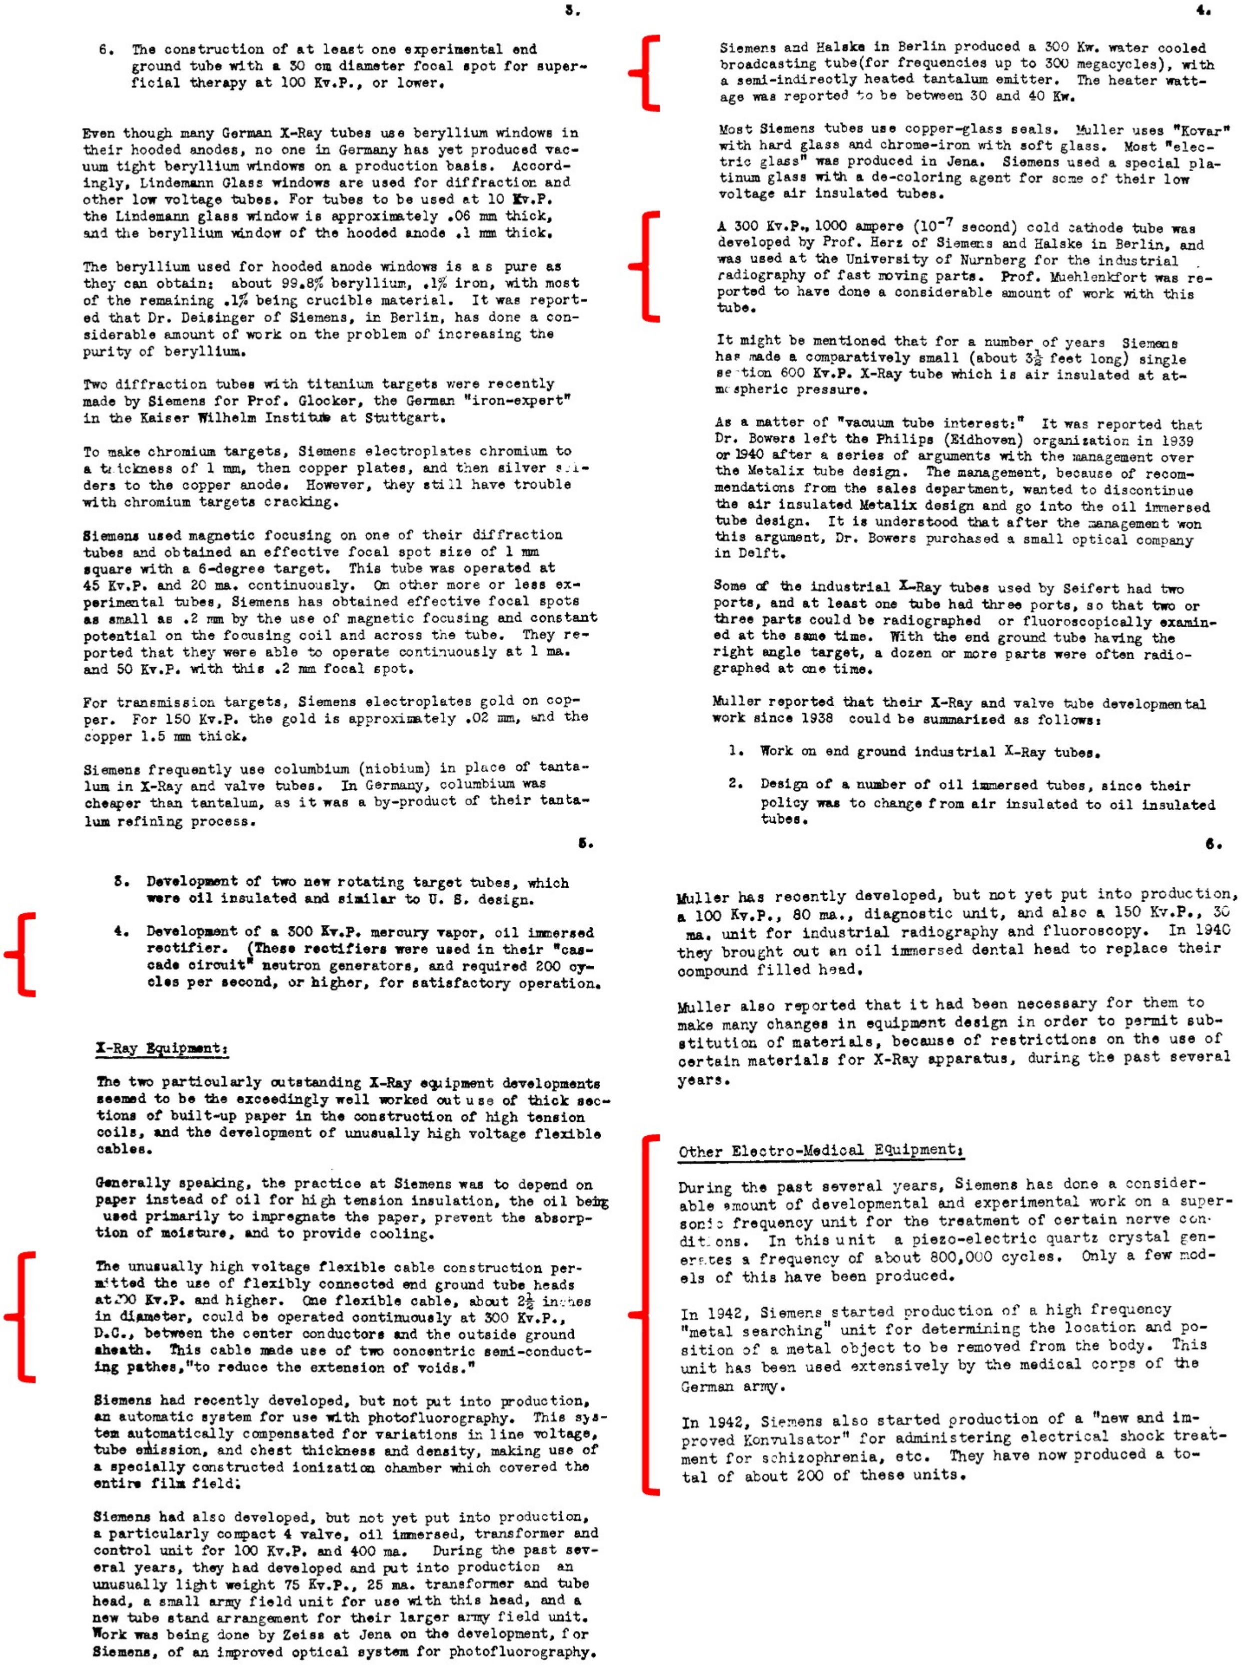
   This process was reported to provide a longer life than the previously used process for coating steel balls with graphite.

4. A new Muller process for coating steel balls with lead, for use in rotating target tubes.

5. The use of thoriated tungsten filaments on a few valve tubes up to 120 Kv.P., by both Siemens and Muller.

   It was reported that by using thoriated tungsten filaments, they had succeeded in reducing the filament wattage to about 15% of the wattage required for pure tungsten filaments, but because of the processing difficulties involved, most valve tubes were still being manufactured with pure tungsten filaments, even though a longer life was expected with the thoriated tungsten.

Figure D.440: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



3.

6. The construction of at least one experimental end ground tube with a 30 cm diameter focal spot for superficial therapy at 100 Kv.P., or lower.

Even though many German X-Ray tubes use beryllium windows in their hooded anodes, no one in Germany has yet produced vacuum tight beryllium windows on a production basis. Accordingly, Lindemann Glass windows are used for diffraction and other low voltage tubes. For tubes to be used at 10 Kv.P. the Lindemann glass window is approximately .06 mm thick, and the beryllium window of the hooded anode .1 mm thick.

The beryllium used for hooded anode windows is as pure as they can obtain: about 99.8% beryllium, .1% iron, with most of the remaining .1% being crucible material. It was reported that Dr. Deisinger of Siemens, in Berlin, has done a considerable amount of work on the problem of increasing the purity of beryllium.

Two diffraction tubes with titanium targets were recently made by Siemens for Prof. Glocker, the German "iron-expert" in the Kaiser Wilhelm Institute at Stuttgart.

To make chromium targets, Siemens electroplates chromium to a thickness of 1 mm, then copper plates, and then silver solders to the copper anode. However, they still have trouble with chromium targets cracking.

Siemens used magnetic focusing on one of their diffraction tubes and obtained an effective focal spot size of 1 mm square with a 6-degree target. This tube was operated at 45 Kv.P. and 20 ma. continuously. On other more or less experimental tubes, Siemens has obtained effective focal spots as small as .2 mm by the use of magnetic focusing and constant potential on the focusing coil and across the tube. They reported that they were able to operate continuously at 1 ma. and 50 Kv.P. with this .2 mm focal spot.

For transmission targets, Siemens electroplates gold on copper. For 150 Kv.P. the gold is approximately .02 mm, and the copper 1.5 mm thick.

Siemens frequently use columbium (niobium) in place of tantalum in X-Ray and valve tubes. In Germany, columbium was cheaper than tantalum, as it was a by-product of their tantalum refining process.

4.

Siemens and Halske in Berlin produced a 300 Kw. water cooled broadcasting tube(for frequencies up to 300 megacycles), with a semi-indirectly heated tantalum emitter. The heater wattage was reported to be between 30 and 40 Kw.

Most Siemens tubes use copper-glass seals. Muller uses "Kovar" with hard glass and chrome-iron with soft glass. Most "electric glass" was produced in Jena. Siemens used a special platinum glass with a de-coloring agent for some of their low voltage air insulated tubes.

A 300 Kv.P., 1000 ampere (10^{-7} second) cold cathode tube was developed by Prof. Herz of Siemens and Halske in Berlin, and was used at the University of Nurnberg for the industrial radiography of fast moving parts. Prof. Muehlenkfort was reported to have done a considerable amount of work with this tube.

It might be mentioned that for a number of years Siemens has made a comparatively small (about 3½ feet long) single section 600 Kv.P. X-Ray tube which is air insulated at atmospheric pressure.

As a matter of "vacuum tube interest:" It was reported that Dr. Bowers left the Philips (Eidhoven) organization in 1939 or 1940 after a series of arguments with the management over the Metalix tube design. The management, because of recommendations from the sales department, wanted to discontinue the air insulated Metalix design and go into the oil immersed tube design. It is understood that after the management won this argument, Dr. Bowers purchased a small optical company in Delft.

Some of the industrial X-Ray tubes used by Seifert had two ports, and at least one tube had three ports, so that two or three parts could be radiographed or fluoroscopically examined at the same time. With the end ground tube having the right angle target, a dozen or more parts were often radiographed at one time.

Muller reported that their X-Ray and valve tube developmental work since 1938 could be summarized as follows:

1. Work on end ground industrial X-Ray tubes.
2. Design of a number of oil immersed tubes, since their policy was to change from air insulated to oil insulated tubes.

5.

3. Development of two new rotating target tubes, which were oil insulated and similar to U. S. design.
4. Development of a 300 Kv.P. mercury vapor, oil immersed rectifier. (These rectifiers were used in their "cascade circuit" neutron generators, and required 200 cycles per second, or higher, for satisfactory operation.

X-Ray Equipment:

The two particularly outstanding X-Ray equipment developments seemed to be the exceedingly well worked out use of thick sections of built-up paper in the construction of high tension coils, and the development of unusually high voltage flexible cables.

Generally speaking, the practice at Siemens was to depend on paper instead of oil for high tension insulation, the oil being used primarily to impregnate the paper, prevent the absorption of moisture, and to provide cooling.

The unusually high voltage flexible cable construction permitted the use of flexibly connected end ground tube heads at 200 Kv.P. and higher. One flexible cable, about 2½ inches in diameter, could be operated continuously at 300 Kv.P., D.C., between the center conductors and the outside ground sheath. This cable made use of two concentric semi-conducting pathes,"to reduce the extension of voids."

Siemens had recently developed, but not put into production, an automatic system for use with photofluorography. This system automatically compensated for variations in line voltage, tube emission, and chest thickness and density, making use of a specially constructed ionization chamber which covered the entire film field:

Siemens had also developed, but not yet put into production, a particularly compact 4 valve, oil immersed, transformer and control unit for 100 Kv.P. and 400 ma. During the past several years, they had developed and put into production an unusually light weight 75 Kv.P., 25 ma. transformer and tube head, a small army field unit for use with this head, and a new tube stand arrangement for their larger army field unit. Work was being done by Zeiss at Jena on the development, for Siemens, of an improved optical system for photofluorography.

6.

Muller has recently developed, but not yet put into production, a 100 Kv.P., 80 ma., diagnostic unit, and also a 150 Kv.P., 30 ma. unit for industrial radiography and fluoroscopy. In 1940 they brought out an oil immersed dental head to replace their compound filled head.

Muller also reported that it had been necessary for them to make many changes in equipment design in order to permit substitution of materials, because of restrictions on the use of certain materials for X-Ray apparatus, during the past several years.

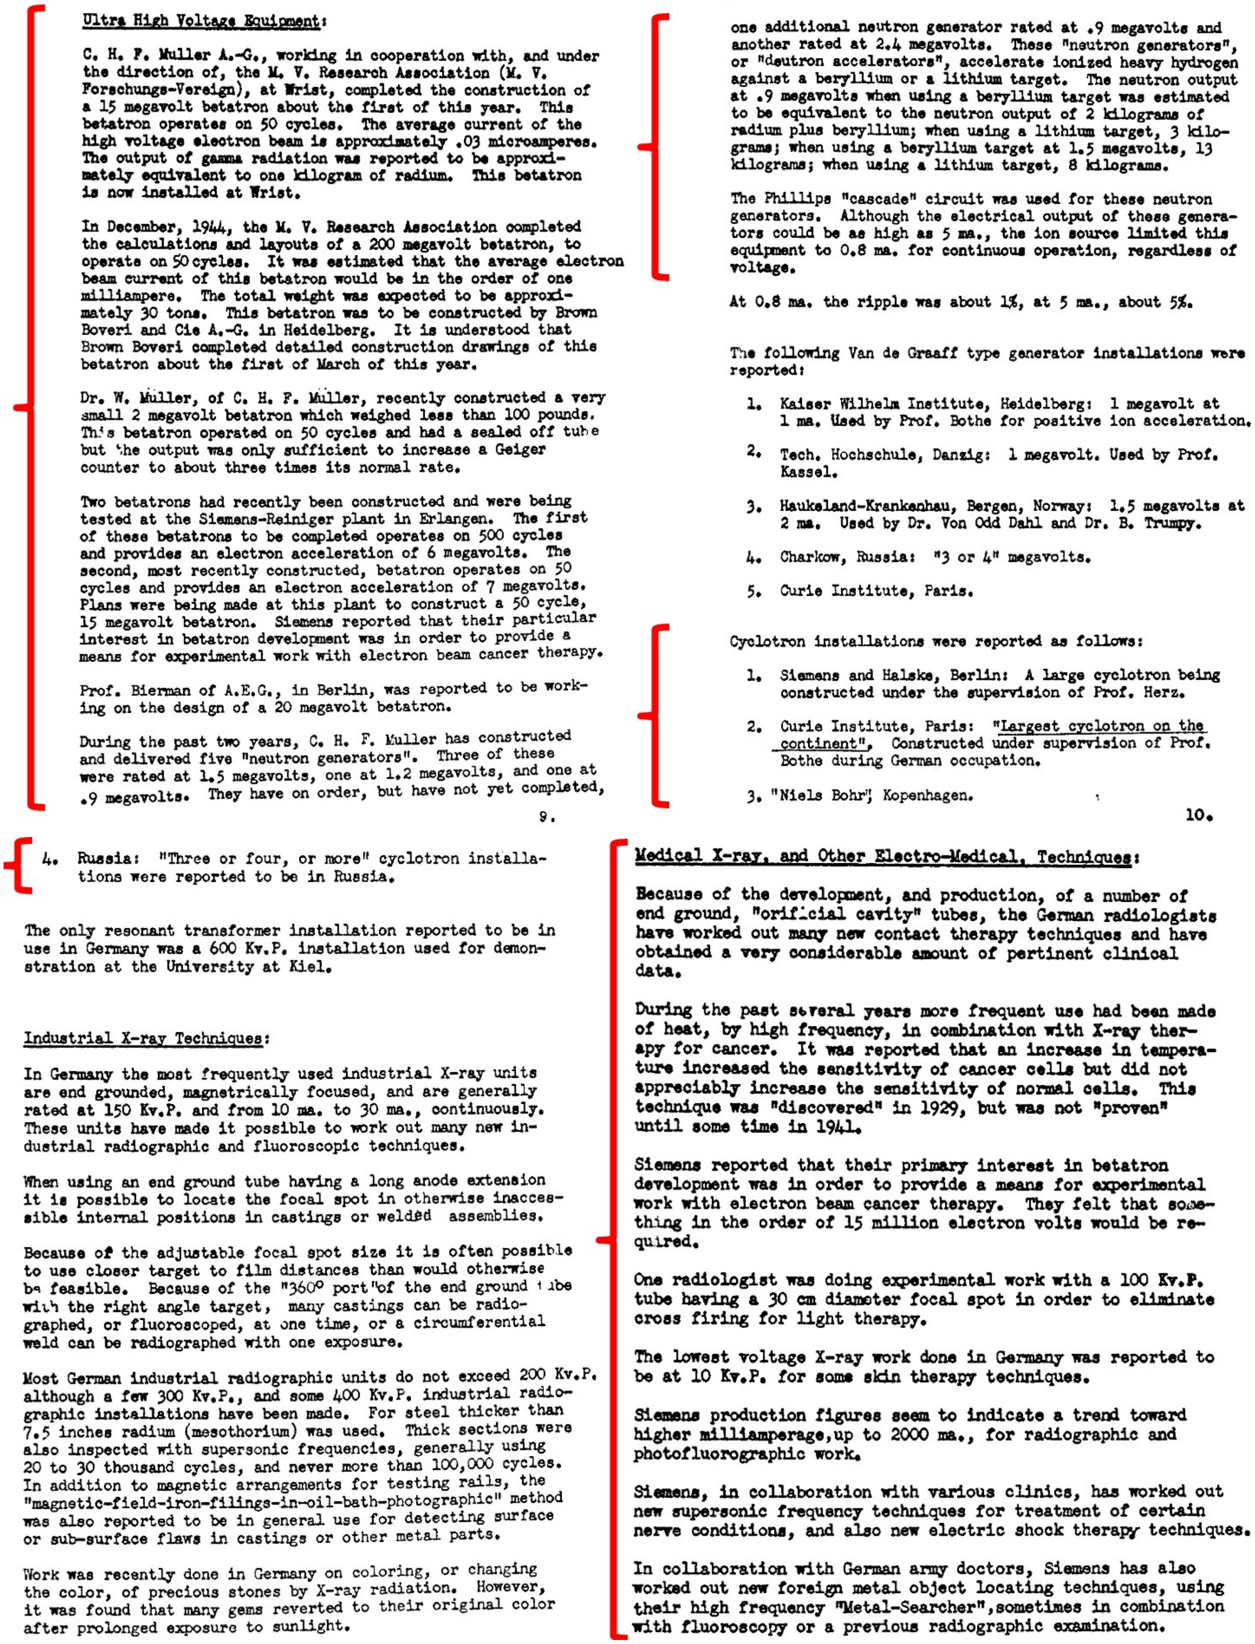
Other Electro-Medical Equipment:

During the past several years, Siemens has done a considerable amount of developmental and experimental work on a supersonic frequency unit for the treatment of certain nerve conditions. In this unit a piezo-electric quartz crystal generates a frequency of about 800,000 cycles. Only a few models of this have been produced.

In 1942, Siemens started production of a high frequency "metal searching" unit for determining the location and position of a metal object to be removed from the body. This unit has been used extensively by the medical corps of the German army.

In 1942, Siemens also started production of a "new and improved Konvulsator" for administering electrical shock treatment for schizophrenia, etc. They have now produced a total of about 200 of these units.

Figure D.441: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



Ultra High Voltage Equipment:

C. H. F. Muller A.-G., working in cooperation with, and under the direction of, the M. V. Research Association (M. V. Forschungs-Verein), at Wrist, completed the construction of a 15 megavolt betatron about the first of this year. This betatron operates on 50 cycles. The average current of the high voltage electron beam is approximately .03 microamperes. The output of gamma radiation was reported to be approximately equivalent to one kilogram of radium. This betatron is now installed at Wrist.

In December, 1944, the M. V. Research Association completed the calculations and layouts of a 200 megavolt betatron, to operate on 50 cycles. It was estimated that the average electron beam current of this betatron would be in the order of one milliampere. The total weight was expected to be approximately 30 tons. This betatron was to be constructed by Brown Boveri and Cie A.-G. in Heidelberg. It is understood that Brown Boveri completed detailed construction drawings of this betatron about the first of March of this year.

Dr. W. Müller, of C. H. F. Müller, recently constructed a very small 2 megavolt betatron which weighed less than 100 pounds. This betatron operated on 50 cycles and had a sealed off tube but the output was only sufficient to increase a Geiger counter to about three times its normal rate.

Two betatrons had recently been constructed and were being tested at the Siemens-Reiniger plant in Erlangen. The first of these betatrons to be completed operates on 500 cycles and provides an electron acceleration of 6 megavolts. The second, most recently constructed, betatron operates on 50 cycles and provides an electron acceleration of 7 megavolts. Plans were being made at this plant to construct a 50 cycle, 15 megavolt betatron. Siemens reported that their particular interest in betatron development was in order to provide a means for experimental work with electron beam cancer therapy.

Prof. Bierman of A.E.G., in Berlin, was reported to be working on the design of a 20 megavolt betatron.

During the past two years, C. H. F. Muller has constructed and delivered five "neutron generators". Three of these were rated at 1.5 megavolts, one at 1.2 megavolts, and one at .9 megavolts. They have on order, but have not yet completed,

one additional neutron generator rated at .9 megavolts and another rated at 2.4 megavolts. These "neutron generators", or "deutron accelerators", accelerate ionized heavy hydrogen against a beryllium or a lithium target. The neutron output at .9 megavolts when using a beryllium target was estimated to be equivalent to the neutron output of 2 kilograms of radium plus beryllium; when using a lithium target, 3 kilograms; when using a beryllium target at 1.5 megavolts, 13 kilograms; when using a lithium target, 8 kilograms.

The Phillips "cascade" circuit was used for these neutron generators. Although the electrical output of these generators could be as high as 5 ma., the ion source limited this equipment to 0.8 ma. for continuous operation, regardless of voltage.

At 0.8 ma. the ripple was about 1%, at 5 ma., about 5%.

The following Van de Graaff type generator installations were reported:

1. Kaiser Wilhelm Institute, Heidelberg: 1 megavolt at 1 ma. Used by Prof. Bothe for positive ion acceleration.
2. Tech. Hochschule, Danzig: 1 megavolt. Used by Prof. Kassel.
3. Haukeland-Krankenhau, Bergen, Norway: 1.5 megavolts at 2 ma. Used by Dr. Von Odd Dahl and Dr. B. Trumpy.
4. Charkow, Russia: "3 or 4" megavolts.
5. Curie Institute, Paris.

Cyclotron installations were reported as follows:

1. Siemens and Halske, Berlin: A large cyclotron being constructed under the supervision of Prof. Herz.
2. Curie Institute, Paris: "Largest cyclotron on the continent". Constructed under supervision of Prof. Bothe during German occupation.
3. "Niels Bohr", Kopenhagen.

4. Russia: "Three or four, or more" cyclotron installations were reported to be in Russia.

The only resonant transformer installation reported to be in use in Germany was a 600 Kv.P. installation used for demonstration at the University at Kiel.

Industrial X-ray Techniques:

In Germany the most frequently used industrial X-ray units are end grounded, magnetrically focused, and are generally rated at 150 Kv.P. and from 10 ma. to 30 ma., continuously. These units have made it possible to work out many new industrial radiographic and fluoroscopic techniques.

When using an end ground tube having a long anode extension it is possible to locate the focal spot in otherwise inaccessible internal positions in castings or welded assemblies.

Because of the adjustable focal spot size it is often possible to use closer target to film distances than would otherwise be feasible. Because of the "360° port" of the end ground tube with the right angle target, many castings can be radiographed, or fluoroscoped, at one time, or a circumferential weld can be radiographed with one exposure.

Most German industrial radiographic units do not exceed 200 Kv.P. although a few 300 Kv.P., and some 400 Kv.P. industrial radiographic installations have been made. For steel thicker than 7.5 inches radium (mesothorium) was used. Thick sections were also inspected with supersonic frequencies, generally using 20 to 30 thousand cycles, and never more than 100,000 cycles. In addition to magnetic arrangements for testing rails, the "magnetic-field-iron-filings-in-oil-bath-photographic" method was also reported to be in general use for detecting surface or sub-surface flaws in castings or other metal parts.

Work was recently done in Germany on coloring, or changing the color, of precious stones by X-ray radiation. However, it was found that many gems reverted to their original color after prolonged exposure to sunlight.

Medical X-ray, and Other Electro-Medical, Techniques:

Because of the development, and production, of a number of end ground, "orificial cavity" tubes, the German radiologists have worked out many new contact therapy techniques and have obtained a very considerable amount of pertinent clinical data.

During the past several years more frequent use had been made of heat, by high frequency, in combination with X-ray therapy for cancer. It was reported that an increase in temperature increased the sensitivity of cancer cells but did not appreciably increase the sensitivity of normal cells. This technique was "discovered" in 1929, but was not "proven" until some time in 1941.

Siemens reported that their primary interest in betatron development was in order to provide a means for experimental work with electron beam cancer therapy. They felt that something in the order of 15 million electron volts would be required.

One radiologist was doing experimental work with a 100 Kv.P. tube having a 30 cm diameter focal spot in order to eliminate cross firing for light therapy.

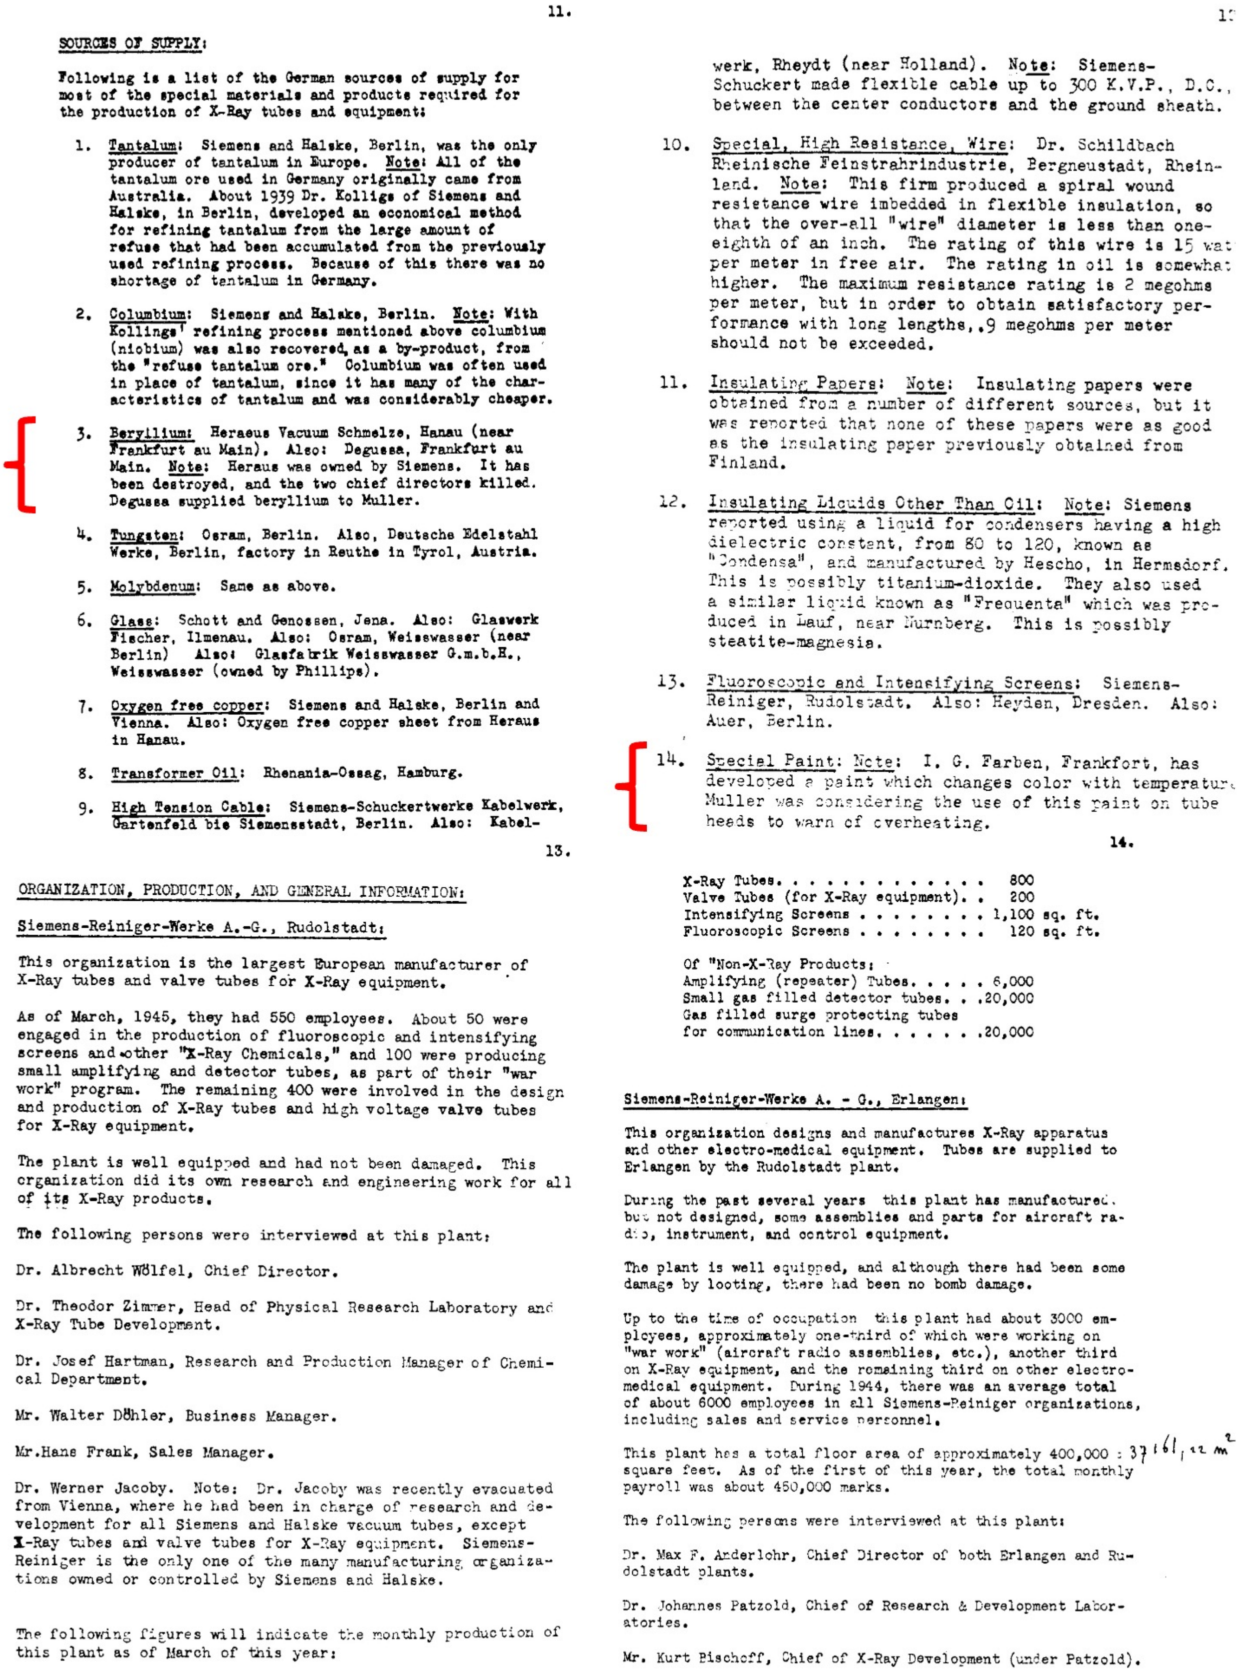
The lowest voltage X-ray work done in Germany was reported to be at 10 Kv.P. for some skin therapy techniques.

Siemens production figures seem to indicate a trend toward higher milliamperage, up to 2000 ma., for radiographic and photofluorographic work.

Siemens, in collaboration with various clinics, has worked out new supersonic frequency techniques for treatment of certain nerve conditions, and also new electric shock therapy techniques.

In collaboration with German army doctors, Siemens has also worked out new foreign metal object locating techniques, using their high frequency "Metal-Searcher", sometimes in combination with fluoroscopy or a previous radiographic examination.

Figure D.442: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



11.

SOURCES OF SUPPLY:

Following is a list of the German sources of supply for most of the special materials and products required for the production of X-Ray tubes and equipment:

1. Tantalum: Siemens and Halske, Berlin, was the only producer of tantalum in Europe. Note: All of the tantalum ore used in Germany originally came from Australia. About 1939 Dr. Kolligs of Siemens and Halske, in Berlin, developed an economical method for refining tantalum from the large amount of refuse that had been accumulated from the previously used refining process. Because of this there was no shortage of tantalum in Germany.
2. Columbium: Siemens and Halske, Berlin. Note: With Kollings' refining process mentioned above columbium (niobium) was also recovered, as a by-product, from the "refuse tantalum ore." Columbium was often used in place of tantalum, since it has many of the characteristics of tantalum and was considerably cheaper.
3. Beryllium: Heraeus Vacuum Schmelze, Hanau (near Frankfurt au Main). Also: Degussa, Frankfurt au Main. Note: Heraus was owned by Siemens. It has been destroyed, and the two chief directors killed. Degussa supplied beryllium to Muller.
4. Tungsten: Osram, Berlin. Also, Deutsche Edelstahl Werke, Berlin, factory in Reuthe in Tyrol, Austria.
5. Molybdenum: Same as above.
6. Glass: Schott and Genossen, Jena. Also: Glaswerk Fischer, Ilmenau. Also: Osram, Weisswasser (near Berlin) Also: Glasfabrik Weisswasser G.m.b.H., Weisswasser (owned by Phillips).
7. Oxygen free copper: Siemens and Halske, Berlin and Vienna. Also: Oxygen free copper sheet from Heraus in Hanau.
8. Transformer Oil: Rhenania-Ossag, Hamburg.
9. High Tension Cable: Siemens-Schuckertwerke Kabelwerk, Gartenfeld bie Siemensstadt, Berlin. Also: Kabelwerk, Rheydt (near Holland). Note: Siemens-Schuckert made flexible cable up to 300 K.V.P., D.C., between the center conductors and the ground sheath.

1

10. Special, High Resistance, Wire: Dr. Schildbach Rheinische Feinstrahrindustrie, Bergneustadt, Rheinland. Note: This firm produced a spiral wound resistance wire imbedded in flexible insulation, so that the over-all "wire" diameter is less than one-eighth of an inch. The rating of this wire is 15 wat per meter in free air. The rating in oil is somewhat higher. The maximum resistance rating is 2 megohms per meter, but in order to obtain satisfactory performance with long lengths, .9 megohms per meter should not be exceeded.
11. Insulating Papers: Note: Insulating papers were obtained from a number of different sources, but it was reported that none of these papers were as good as the insulating paper previously obtained from Finland.
12. Insulating Liquids Other Than Oil: Note: Siemens reported using a liquid for condensers having a high dielectric constant, from 80 to 120, known as "Condensa", and manufactured by Hescho, in Hermsdorf. This is possibly titanium-dioxide. They also used a similar liquid known as "Frequenta" which was produced in Lauf, near Nurnberg. This is possibly steatite-magnesia.
13. Fluoroscopic and Intensifying Screens: Siemens-Reiniger, Rudolstadt. Also: Heyden, Dresden. Also: Auer, Berlin.
14. Special Paint: Note: I. G. Farben, Frankfort, has developed a paint which changes color with temperatur Muller was considering the use of this paint on tube heads to warn of overheating.

13.

ORGANIZATION, PRODUCTION, AND GENERAL INFORMATION:

Siemens-Reiniger-Werke A.-G., Rudolstadt:

This organization is the largest European manufacturer of X-Ray tubes and valve tubes for X-Ray equipment.

As of March, 1945, they had 550 employees. About 50 were engaged in the production of fluoroscopic and intensifying screens and other "X-Ray Chemicals," and 100 were producing small amplifying and detector tubes, as part of their "war work" program. The remaining 400 were involved in the design and production of X-Ray tubes and high voltage valve tubes for X-Ray equipment.

The plant is well equipped and had not been damaged. This organization did its own research and engineering work for all of its X-Ray products.

The following persons were interviewed at this plant:

Dr. Albrecht Wölfel, Chief Director.

Dr. Theodor Zimmer, Head of Physical Research Laboratory and X-Ray Tube Development.

Dr. Josef Hartman, Research and Production Manager of Chemical Department.

Mr. Walter Döhler, Business Manager.

Mr. Hans Frank, Sales Manager.

Dr. Werner Jacoby. Note: Dr. Jacoby was recently evacuated from Vienna, where he had been in charge of research and development for all Siemens and Halske vacuum tubes, except X-Ray tubes and valve tubes for X-Ray equipment. Siemens-Reiniger is the only one of the many manufacturing organizations owned or controlled by Siemens and Halske.

The following figures will indicate the monthly production of this plant as of March of this year:

14.

X-Ray Tubes.	800
Valve Tubes (for X-Ray equipment). .	200
Intensifying Screens	1,100 sq. ft.
Fluoroscopic Screens	120 sq. ft.

Of "Non-X-Ray Products:

Amplifying (repeater) Tubes.	6,000
Small gas filled detector tubes. . .	20,000
Gas filled surge protecting tubes for communication lines.	20,000

Siemens-Reiniger-Werke A. - G., Erlangen:

This organization designs and manufactures X-Ray apparatus and other electro-medical equipment. Tubes are supplied to Erlangen by the Rudolstadt plant.

During the past several years this plant has manufactured, but not designed, some assemblies and parts for aircraft radio, instrument, and control equipment.

The plant is well equipped, and although there had been some damage by looting, there had been no bomb damage.

Up to the time of occupation this plant had about 3000 employees, approximately one-third of which were working on "war work" (aircraft radio assemblies, etc.), another third on X-Ray equipment, and the remaining third on other electro-medical equipment. During 1944, there was an average total of about 6000 employees in all Siemens-Reiniger organizations, including sales and service personnel.

This plant has a total floor area of approximately 400,000 : 37161,12 m^2 square feet. As of the first of this year, the total monthly payroll was about 450,000 marks.

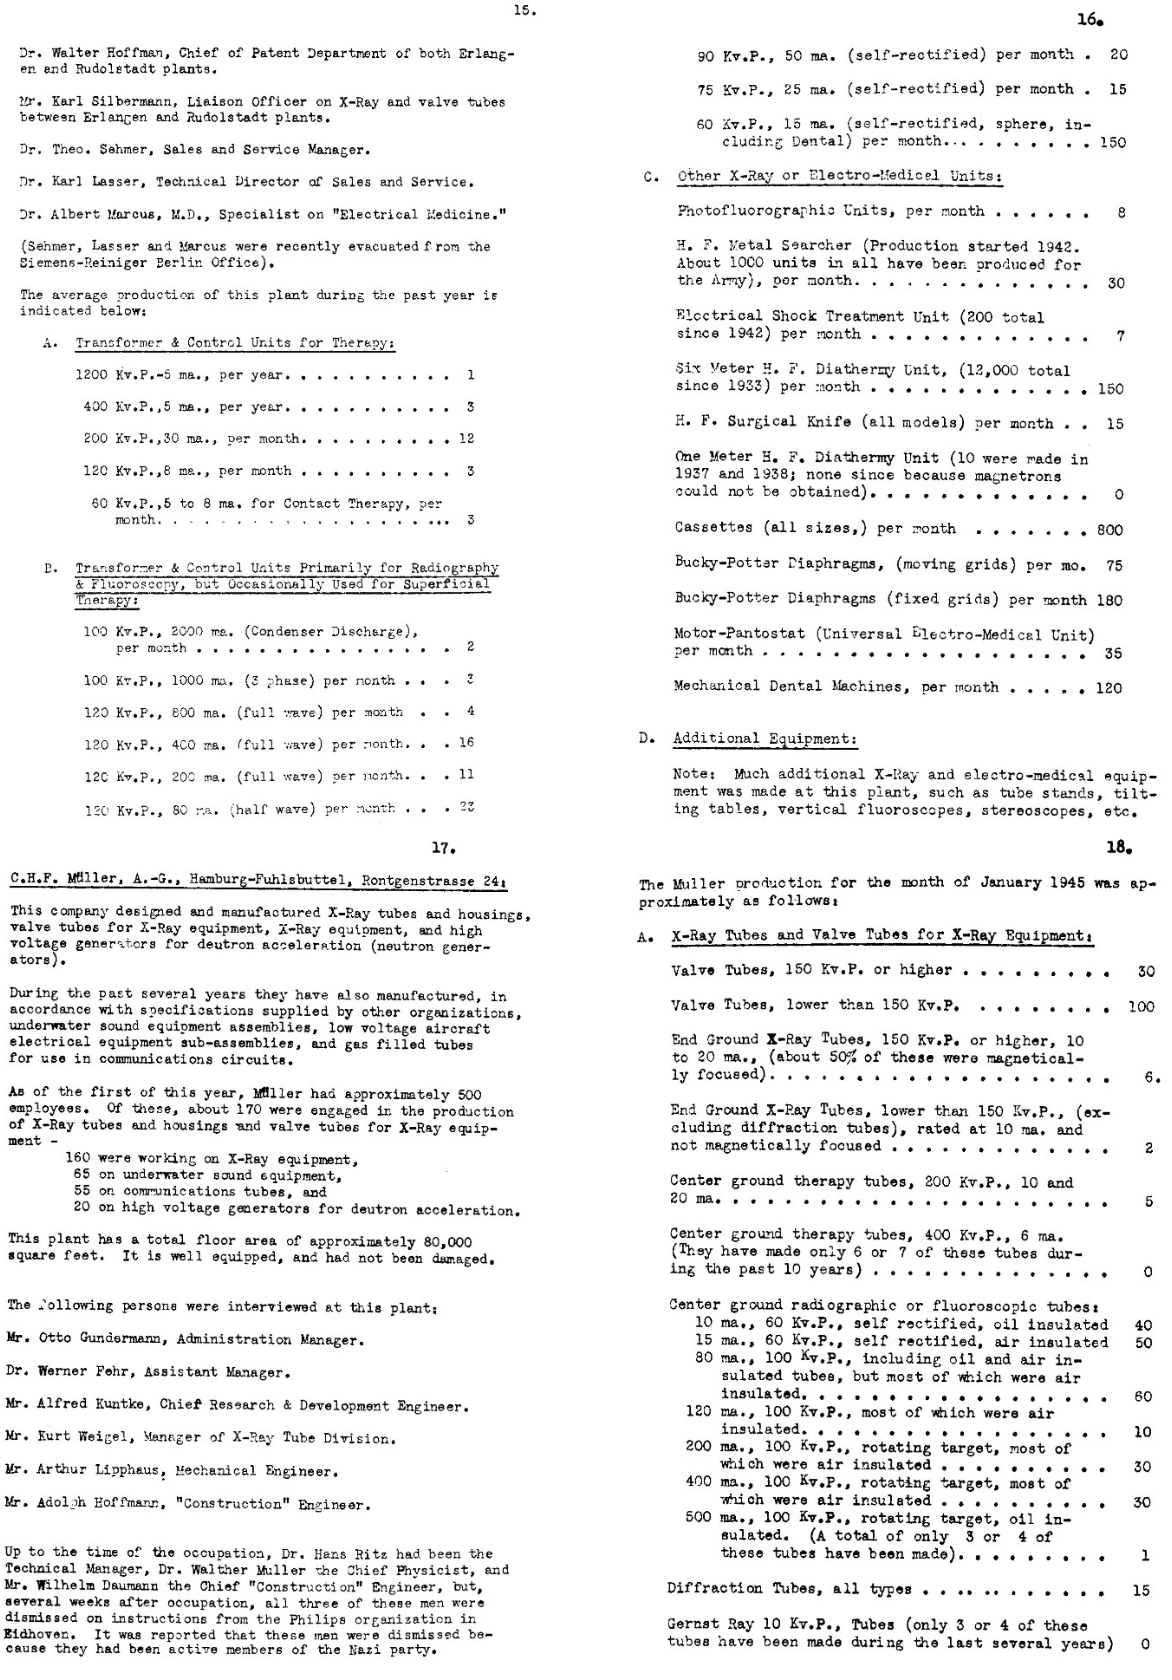
The following persons were interviewed at this plant:

Dr. Max F. Anderlohr, Chief Director of both Erlangen and Rudolstadt plants.

Dr. Johannes Patzold, Chief of Research & Development Laboratories.

Mr. Kurt Bischoff, Chief of X-Ray Development (under Patzold).

Figure D.443: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



Dr. Walter Hoffman, Chief of Patent Department of both Erlangen and Rudolstadt plants.

Mr. Karl Silbermann, Liaison Officer on X-Ray and valve tubes between Erlangen and Rudolstadt plants.

Dr. Theo. Sehmer, Sales and Service Manager.

Dr. Karl Lasser, Technical Director of Sales and Service.

Dr. Albert Marcus, M.D., Specialist on "Electrical Medicine."

(Sehmer, Lasser and Marcus were recently evacuated from the Siemens-Reiniger Berlin Office).

The average production of this plant during the past year is indicated below:

A. Transformer & Control Units for Therapy:

1200 Kv.P.-5 ma., per year	1
400 Kv.P.,5 ma., per year	3
200 Kv.P.,30 ma., per month	12
120 Kv.P.,8 ma., per month	3
60 Kv.P.,5 to 8 ma. for Contact Therapy, per month	3

B. Transformer & Control Units Primarily for Radiography & Fluoroscopy, but Occasionally Used for Superficial Therapy:

100 Kv.P., 2000 ma. (Condenser Discharge), per month	2
100 Kv.P., 1000 ma. (3 phase) per month	3
120 Kv.P., 800 ma. (full wave) per month	4
120 Kv.P., 400 ma. (full wave) per month	16
120 Kv.P., 200 ma. (full wave) per month	11
120 Kv.P., 80 ma. (half wave) per month	23

90 Kv.P., 50 ma. (self-rectified) per month	20
75 Kv.P., 25 ma. (self-rectified) per month	15
60 Kv.P., 15 ma. (self-rectified, sphere, including Dental) per month	150

C. Other X-Ray or Electro-Medical Units:

Photofluorographic Units, per month	8
H. F. Metal Searcher (Production started 1942. About 1000 units in all have been produced for the Army), per month	30
Electrical Shock Treatment Unit (200 total since 1942) per month	7
Six Meter H. F. Diathermy Unit, (12,000 total since 1933) per month	150
H. F. Surgical Knife (all models) per month	15
One Meter H. F. Diathermy Unit (10 were made in 1937 and 1938; none since because magnetrons could not be obtained)	0
Cassettes (all sizes,) per month	800
Bucky-Potter Diaphragms, (moving grids) per mo.	75
Bucky-Potter Diaphragms (fixed grids) per month	180
Motor-Pantostat (Universal Electro-Medical Unit) per month	35
Mechanical Dental Machines, per month	120

D. Additional Equipment:

Note: Much additional X-Ray and electro-medical equipment was made at this plant, such as tube stands, tilting tables, vertical fluoroscopes, stereoscopes, etc.

C.H.F. Müller, A.-G., Hamburg-Fuhlsbuttel, Rontgenstrasse 24:

This company designed and manufactured X-Ray tubes and housings, valve tubes for X-Ray equipment, X-Ray equipment, and high voltage generators for deutron acceleration (neutron generators).

During the past several years they have also manufactured, in accordance with specifications supplied by other organizations, underwater sound equipment assemblies, low voltage aircraft electrical equipment sub-assemblies, and gas filled tubes for use in communications circuits.

As of the first of this year, Müller had approximately 500 employees. Of these, about 170 were engaged in the production of X-Ray tubes and housings and valve tubes for X-Ray equipment -

160 were working on X-Ray equipment,
65 on underwater sound equipment,
55 on communications tubes, and
20 on high voltage generators for deutron acceleration.

This plant has a total floor area of approximately 80,000 square feet. It is well equipped, and had not been damaged.

The following persons were interviewed at this plant:

Mr. Otto Gundermann, Administration Manager.

Dr. Werner Fehr, Assistant Manager.

Mr. Alfred Kuntke, Chief Research & Development Engineer.

Mr. Kurt Weigel, Manager of X-Ray Tube Division.

Mr. Arthur Lipphaus, Mechanical Engineer.

Mr. Adolph Hoffmann, "Construction" Engineer.

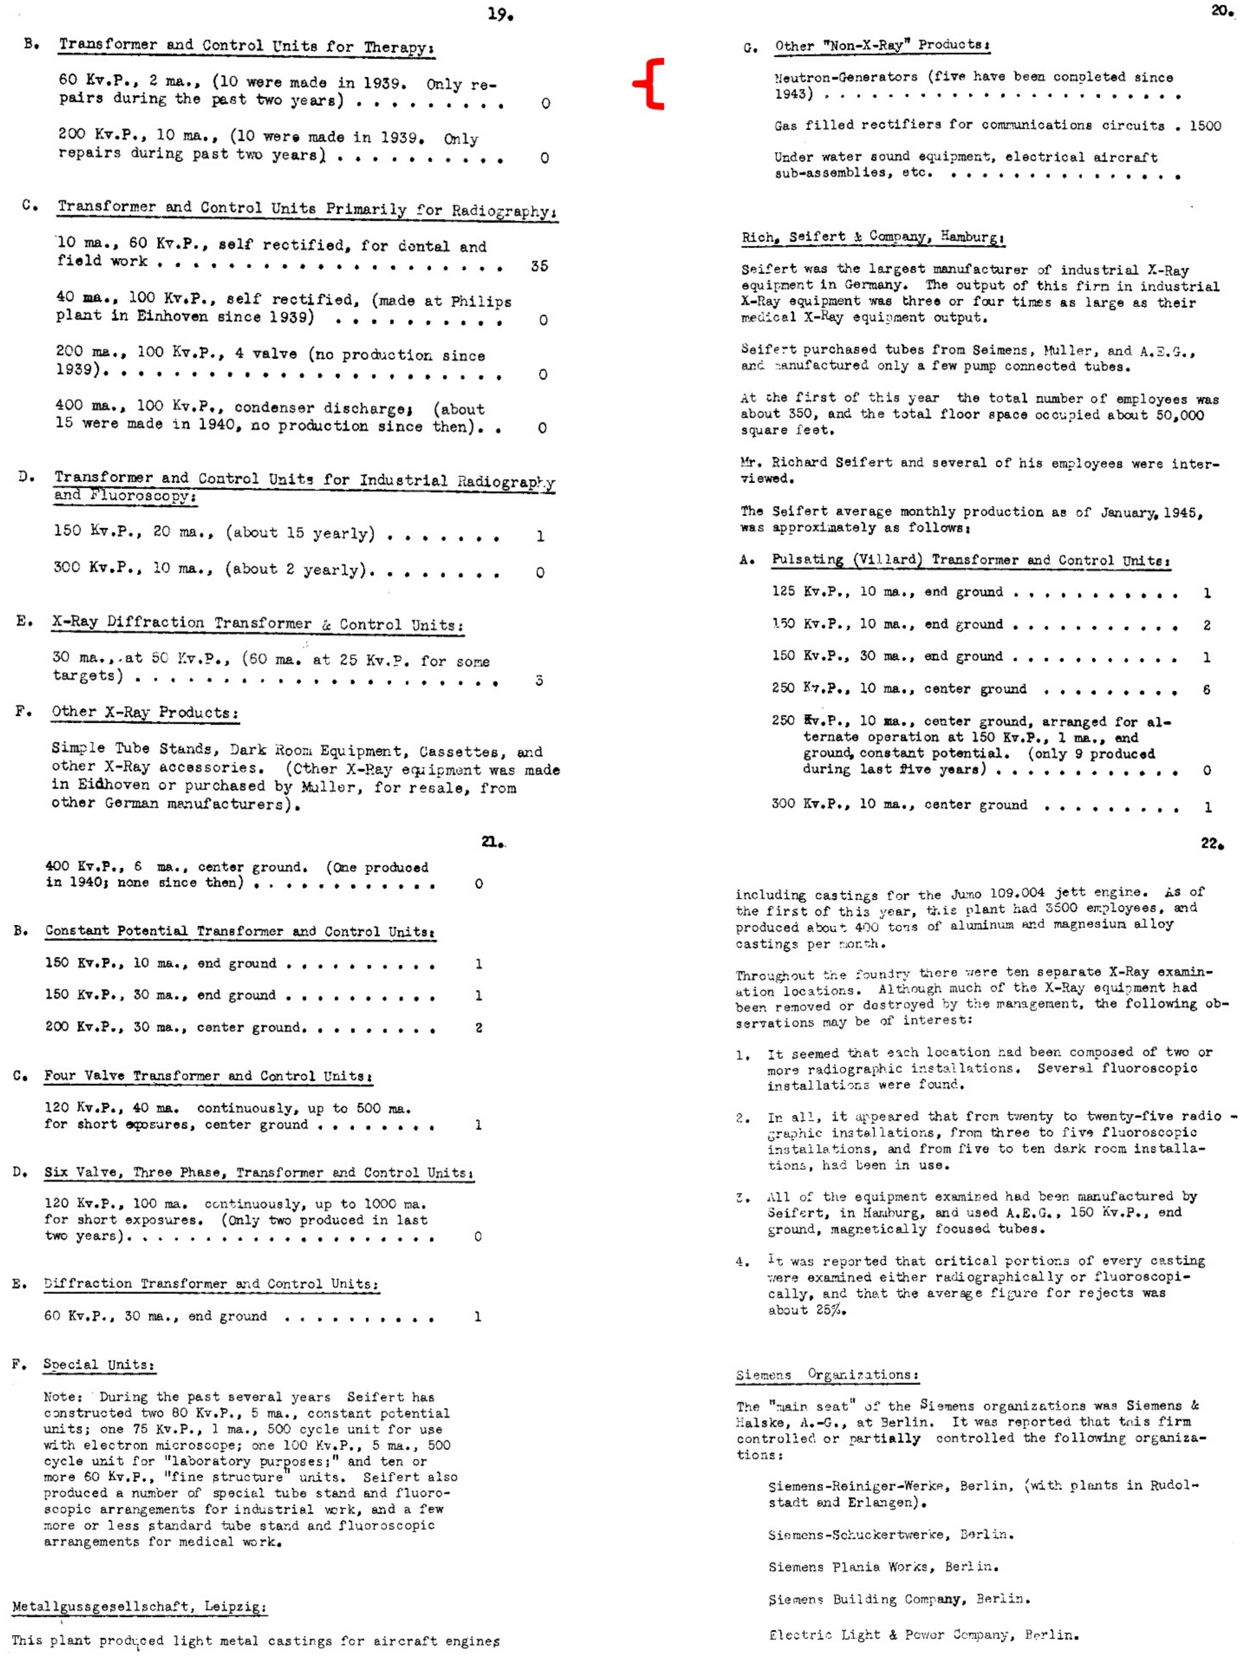
Up to the time of the occupation, Dr. Hans Ritz had been the Technical Manager, Dr. Walther Muller the Chief Physicist, and Mr. Wilhelm Daumann the Chief "Construction" Engineer, but, several weeks after occupation, all three of these men were dismissed on instructions from the Philips organization in Eidhoven. It was reported that these men were dismissed because they had been active members of the Nazi party.

The Muller production for the month of January 1945 was approximately as follows:

A. X-Ray Tubes and Valve Tubes for X-Ray Equipment:

Valve Tubes, 150 Kv.P. or higher	30
Valve Tubes, lower than 150 Kv.P.	100
End Ground X-Ray Tubes, 150 Kv.P. or higher, 10 to 20 ma., (about 50% of these were magnetically focused)	6.
End Ground X-Ray Tubes, lower than 150 Kv.P., (excluding diffraction tubes), rated at 10 ma. and not magnetically focused	2
Center ground therapy tubes, 200 Kv.P., 10 and 20 ma.	5
Center ground therapy tubes, 400 Kv.P., 6 ma. (They have made only 6 or 7 of these tubes during the past 10 years)	0
Center ground radiographic or fluoroscopic tubes:	
10 ma., 60 Kv.P., self rectified, oil insulated	40
15 ma., 60 Kv.P., self rectified, air insulated	50
80 ma., 100 Kv.P., including oil and air insulated tubes, but most of which were air insulated.	60
120 ma., 100 Kv.P., most of which were air insulated.	10
200 ma., 100 Kv.P., rotating target, most of which were air insulated	30
400 ma., 100 Kv.P., rotating target, most of which were air insulated	30
500 ma., 100 Kv.P., rotating target, oil insulated. (A total of only 3 or 4 of these tubes have been made).	1
Diffraction Tubes, all types	15
Gernst Ray 10 Kv.P., Tubes (only 3 or 4 of these tubes have been made during the last several years)	0

Figure D.444: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



19.

B. Transformer and Control Units for Therapy:

60 Kv.P., 2 ma., (10 were made in 1939. Only repairs during the past two years)	0
200 Kv.P., 10 ma., (10 were made in 1939. Only repairs during past two years)	0

C. Transformer and Control Units Primarily for Radiography:

10 ma., 60 Kv.P., self rectified, for dental and field work	35
40 ma., 100 Kv.P., self rectified, (made at Philips plant in Einhoven since 1939)	0
200 ma., 100 Kv.P., 4 valve (no production since 1939).	0
400 ma., 100 Kv.P., condenser discharge; (about 15 were made in 1940, no production since then). .	0

D. Transformer and Control Units for Industrial Radiography and Fluoroscopy:

150 Kv.P., 20 ma., (about 15 yearly)	1
300 Kv.P., 10 ma., (about 2 yearly).	0

E. X-Ray Diffraction Transformer & Control Units:

30 ma., at 50 Kv.P., (60 ma. at 25 Kv.P. for some targets)	3

F. Other X-Ray Products:

Simple Tube Stands, Dark Room Equipment, Cassettes, and other X-Ray accessories. (Other X-Ray equipment was made in Eidhoven or purchased by Muller, for resale, from other German manufacturers).

20.

G. Other "Non-X-Ray" Products:

Neutron-Generators (five have been completed since 1943)	
Gas filled rectifiers for communications circuits .	1500
Under water sound equipment, electrical aircraft sub-assemblies, etc.	

Rich, Seifert & Company, Hamburg:

Seifert was the largest manufacturer of industrial X-Ray equipment in Germany. The output of this firm in industrial X-Ray equipment was three or four times as large as their medical X-Ray equipment output.

Seifert purchased tubes from Seimens, Muller, and A.E.G., and manufactured only a few pump connected tubes.

At the first of this year the total number of employees was about 350, and the total floor space occupied about 50,000 square feet.

Mr. Richard Seifert and several of his employees were interviewed.

The Seifert average monthly production as of January, 1945, was approximately as follows:

A. Pulsating (Villard) Transformer and Control Units:

125 Kv.P., 10 ma., end ground	1
150 Kv.P., 10 ma., end ground	2
150 Kv.P., 30 ma., end ground	1
250 Kv.P., 10 ma., center ground	6
250 Kv.P., 10 ma., center ground, arranged for alternate operation at 150 Kv.P., 1 ma., end ground, constant potential. (only 9 produced during last five years)	0
300 Kv.P., 10 ma., center ground	1

21.

400 Kv.P., 6 ma., center ground. (One produced in 1940; none since then)	0

B. Constant Potential Transformer and Control Units:

150 Kv.P., 10 ma., end ground	1
150 Kv.P., 30 ma., end ground	1
200 Kv.P., 30 ma., center ground.	2

C. Four Valve Transformer and Control Units:

120 Kv.P., 40 ma. continuously, up to 500 ma. for short exposures, center ground	1

D. Six Valve, Three Phase, Transformer and Control Units:

120 Kv.P., 100 ma. continuously, up to 1000 ma. for short exposures. (Only two produced in last two years).	0

E. Diffraction Transformer and Control Units:

60 Kv.P., 30 ma., end ground	1

F. Special Units:

Note: During the past several years Seifert has constructed two 80 Kv.P., 5 ma., constant potential units; one 75 Kv.P., 1 ma., 500 cycle unit for use with electron microscope; one 100 Kv.P., 5 ma., 500 cycle unit for "laboratory purposes;" and ten or more 60 Kv.P., "fine structure" units. Seifert also produced a number of special tube stand and fluoroscopic arrangements for industrial work, and a few more or less standard tube stand and fluoroscopic arrangements for medical work.

Metallgussgesellschaft, Leipzig:

This plant produced light metal castings for aircraft engines

22.

including castings for the Jumo 109.004 jett engine. As of the first of this year, this plant had 3500 employees, and produced about 400 tons of aluminum and magnesium alloy castings per month.

Throughout the foundry there were ten separate X-Ray examination locations. Although much of the X-Ray equipment had been removed or destroyed by the management, the following observations may be of interest:

1. It seemed that each location had been composed of two or more radiographic installations. Several fluoroscopic installations were found.
2. In all, it appeared that from twenty to twenty-five radiographic installations, from three to five fluoroscopic installations, and from five to ten dark room installations, had been in use.
3. All of the equipment examined had been manufactured by Seifert, in Hamburg, and used A.E.G., 150 Kv.P., end ground, magnetically focused tubes.
4. It was reported that critical portions of every casting were examined either radiographically or fluoroscopically, and that the average figure for rejects was about 25%.

Siemens Organizations:

The "main seat" of the Siemens organizations was Siemens & Halske, A.-G., at Berlin. It was reported that this firm controlled or partially controlled the following organizations:

Siemens-Reiniger-Werke, Berlin, (with plants in Rudolstadt and Erlangen).

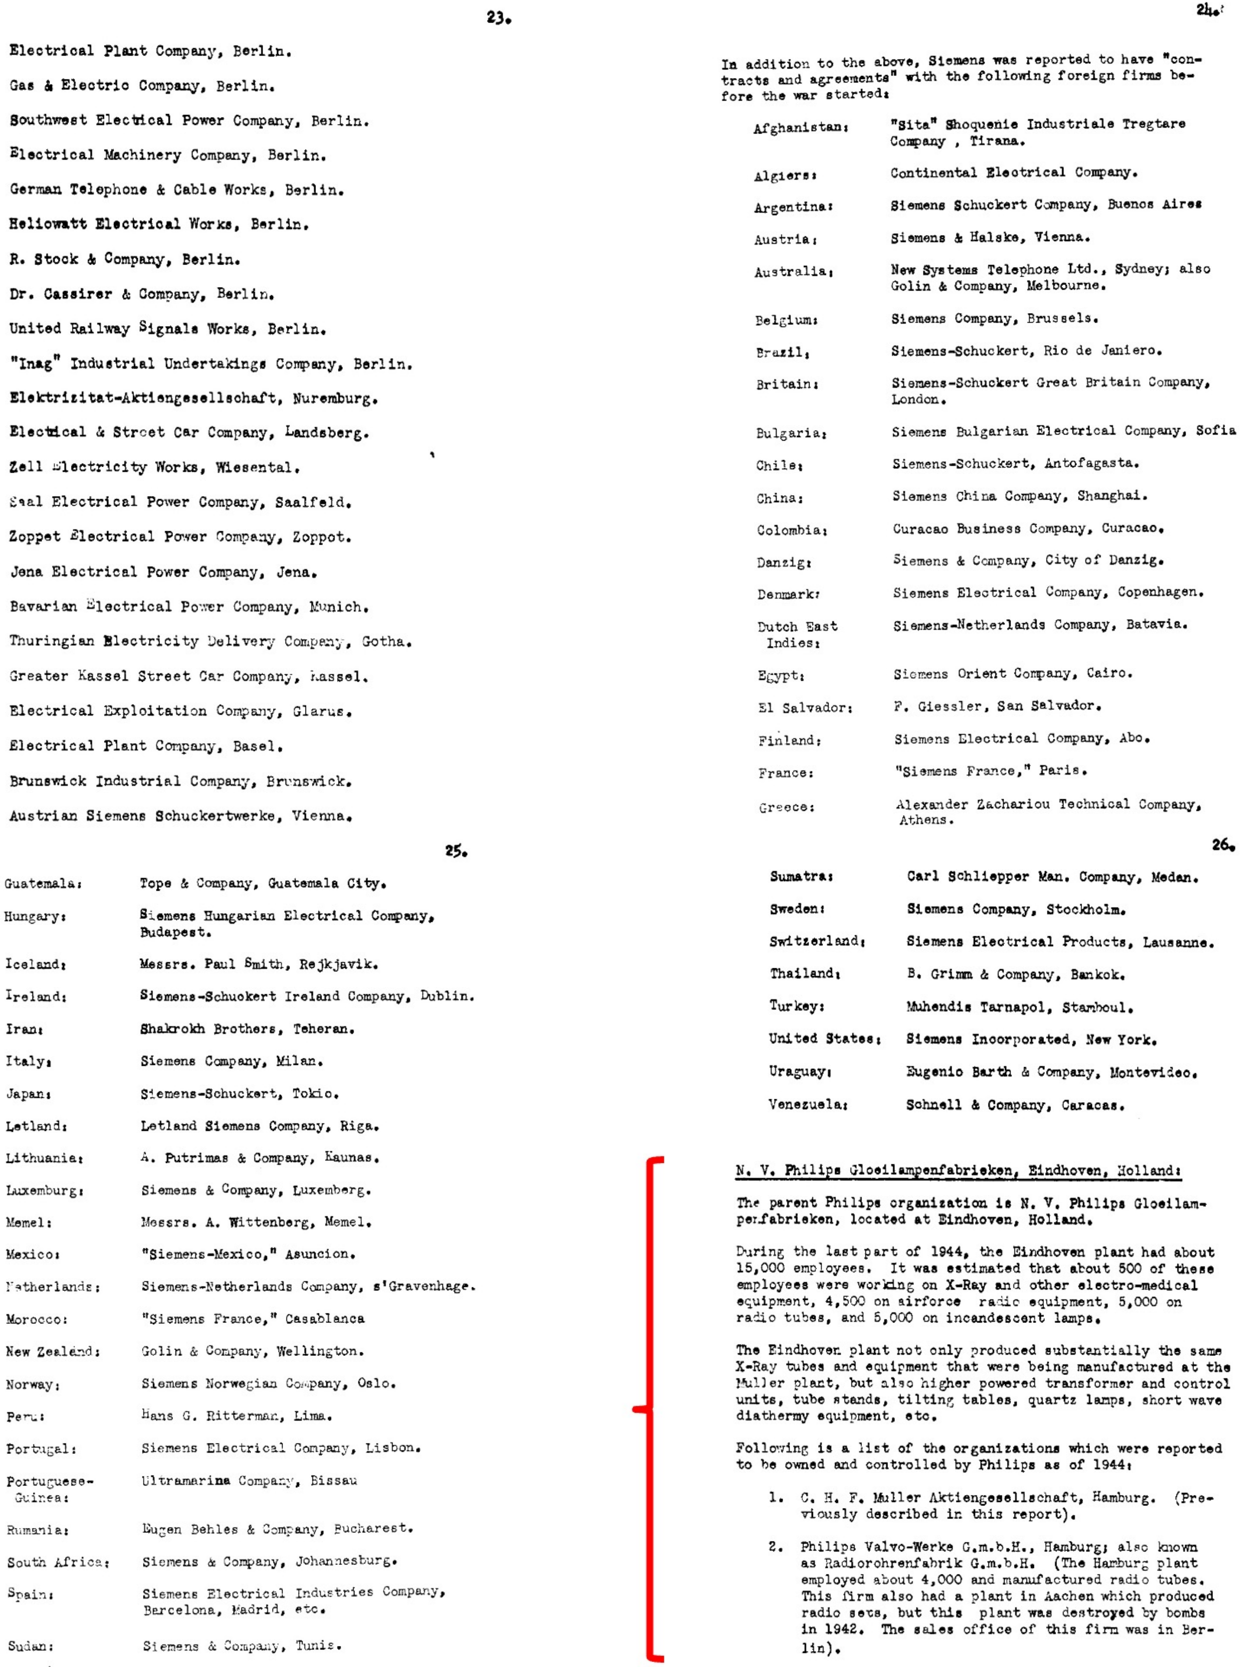
Siemens-Schuckertwerke, Berlin.

Siemens Plania Works, Berlin.

Siemens Building Company, Berlin.

Electric Light & Power Company, Berlin.

Figure D.445: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.
]



23.

Electrical Plant Company, Berlin.

Gas & Electric Company, Berlin.

Southwest Electrical Power Company, Berlin.

Electrical Machinery Company, Berlin.

German Telephone & Cable Works, Berlin.

Heliowatt Electrical Works, Berlin.

R. Stock & Company, Berlin.

Dr. Cassirer & Company, Berlin.

United Railway Signals Works, Berlin.

"Inag" Industrial Undertakings Company, Berlin.

Elektrizitat-Aktiengesellschaft, Nuremburg.

Electrical & Street Car Company, Landsberg.

Zell Electricity Works, Wiesental.

Saal Electrical Power Company, Saalfeld.

Zoppet Electrical Power Company, Zoppot.

Jena Electrical Power Company, Jena.

Bavarian Electrical Power Company, Munich.

Thuringian Electricity Delivery Company, Gotha.

Greater Kassel Street Car Company, Kassel.

Electrical Exploitation Company, Glarus.

Electrical Plant Company, Basel.

Brunswick Industrial Company, Brunswick.

Austrian Siemens Schuckertwerke, Vienna.

24.

In addition to the above, Siemens was reported to have "contracts and agreements" with the following foreign firms before the war started:

Afghanistan:	"Sita" Shoquenie Industriale Tregtare Company, Tirana.
Algiers:	Continental Electrical Company.
Argentina:	Siemens Schuckert Company, Buenos Aires
Austria:	Siemens & Halske, Vienna.
Australia:	New Systems Telephone Ltd., Sydney; also Golin & Company, Melbourne.
Belgium:	Siemens Company, Brussels.
Brazil:	Siemens-Schuckert, Rio de Janiero.
Britain:	Siemens-Schuckert Great Britain Company, London.
Bulgaria:	Siemens Bulgarian Electrical Company, Sofia
Chile:	Siemens-Schuckert, Antofagasta.
China:	Siemens China Company, Shanghai.
Colombia:	Curacao Business Company, Curacao.
Danzig:	Siemens & Company, City of Danzig.
Denmark:	Siemens Electrical Company, Copenhagen.
Dutch East Indies:	Siemens-Netherlands Company, Batavia.
Egypt:	Siemens Orient Company, Cairo.
El Salvador:	F. Giessler, San Salvador.
Finland:	Siemens Electrical Company, Abo.
France:	"Siemens France," Paris.
Greece:	Alexander Zachariou Technical Company, Athens.

25.

Guatemala:	Tope & Company, Guatemala City.
Hungary:	Siemens Hungarian Electrical Company, Budapest.
Iceland:	Messrs. Paul Smith, Rejkjavik.
Ireland:	Siemens-Schuckert Ireland Company, Dublin.
Iran:	Shakrokh Brothers, Teheran.
Italy:	Siemens Company, Milan.
Japan:	Siemens-Schuckert, Tokio.
Letland:	Letland Siemens Company, Riga.
Lithuania:	A. Putrimas & Company, Kaunas.
Luxemburg:	Siemens & Company, Luxemberg.
Memel:	Messrs. A. Wittenberg, Memel.
Mexico:	"Siemens-Mexico," Asuncion.
Netherlands:	Siemens-Netherlands Company, s'Gravenhage.
Morocco:	"Siemens France," Casablanca
New Zealand:	Golin & Company, Wellington.
Norway:	Siemens Norwegian Company, Oslo.
Peru:	Hans G. Ritterman, Lima.
Portugal:	Siemens Electrical Company, Lisbon.
Portuguese-Guinea:	Ultramarina Company, Bissau
Rumania:	Eugen Behles & Company, Bucharest.
South Africa:	Siemens & Company, Johannesburg.
Spain:	Siemens Electrical Industries Company, Barcelona, Madrid, etc.
Sudan:	Siemens & Company, Tunis.

26.

Sumatra:	Carl Schliepper Man. Company, Medan.
Sweden:	Siemens Company, Stockholm.
Switzerland:	Siemens Electrical Products, Lausanne.
Thailand:	B. Grimm & Company, Bankok.
Turkey:	Muhendis Tarnapol, Stamboul.
United States:	Siemens Incorporated, New York.
Uraguay:	Eugenio Barth & Company, Montevideo.
Venezuela:	Schnell & Company, Caracas.

N. V. Philips Gloeilampenfabrieken, Eindhoven, Holland:

The parent Philips organization is N. V. Philips Gloeilampenfabrieken, located at Eindhoven, Holland.

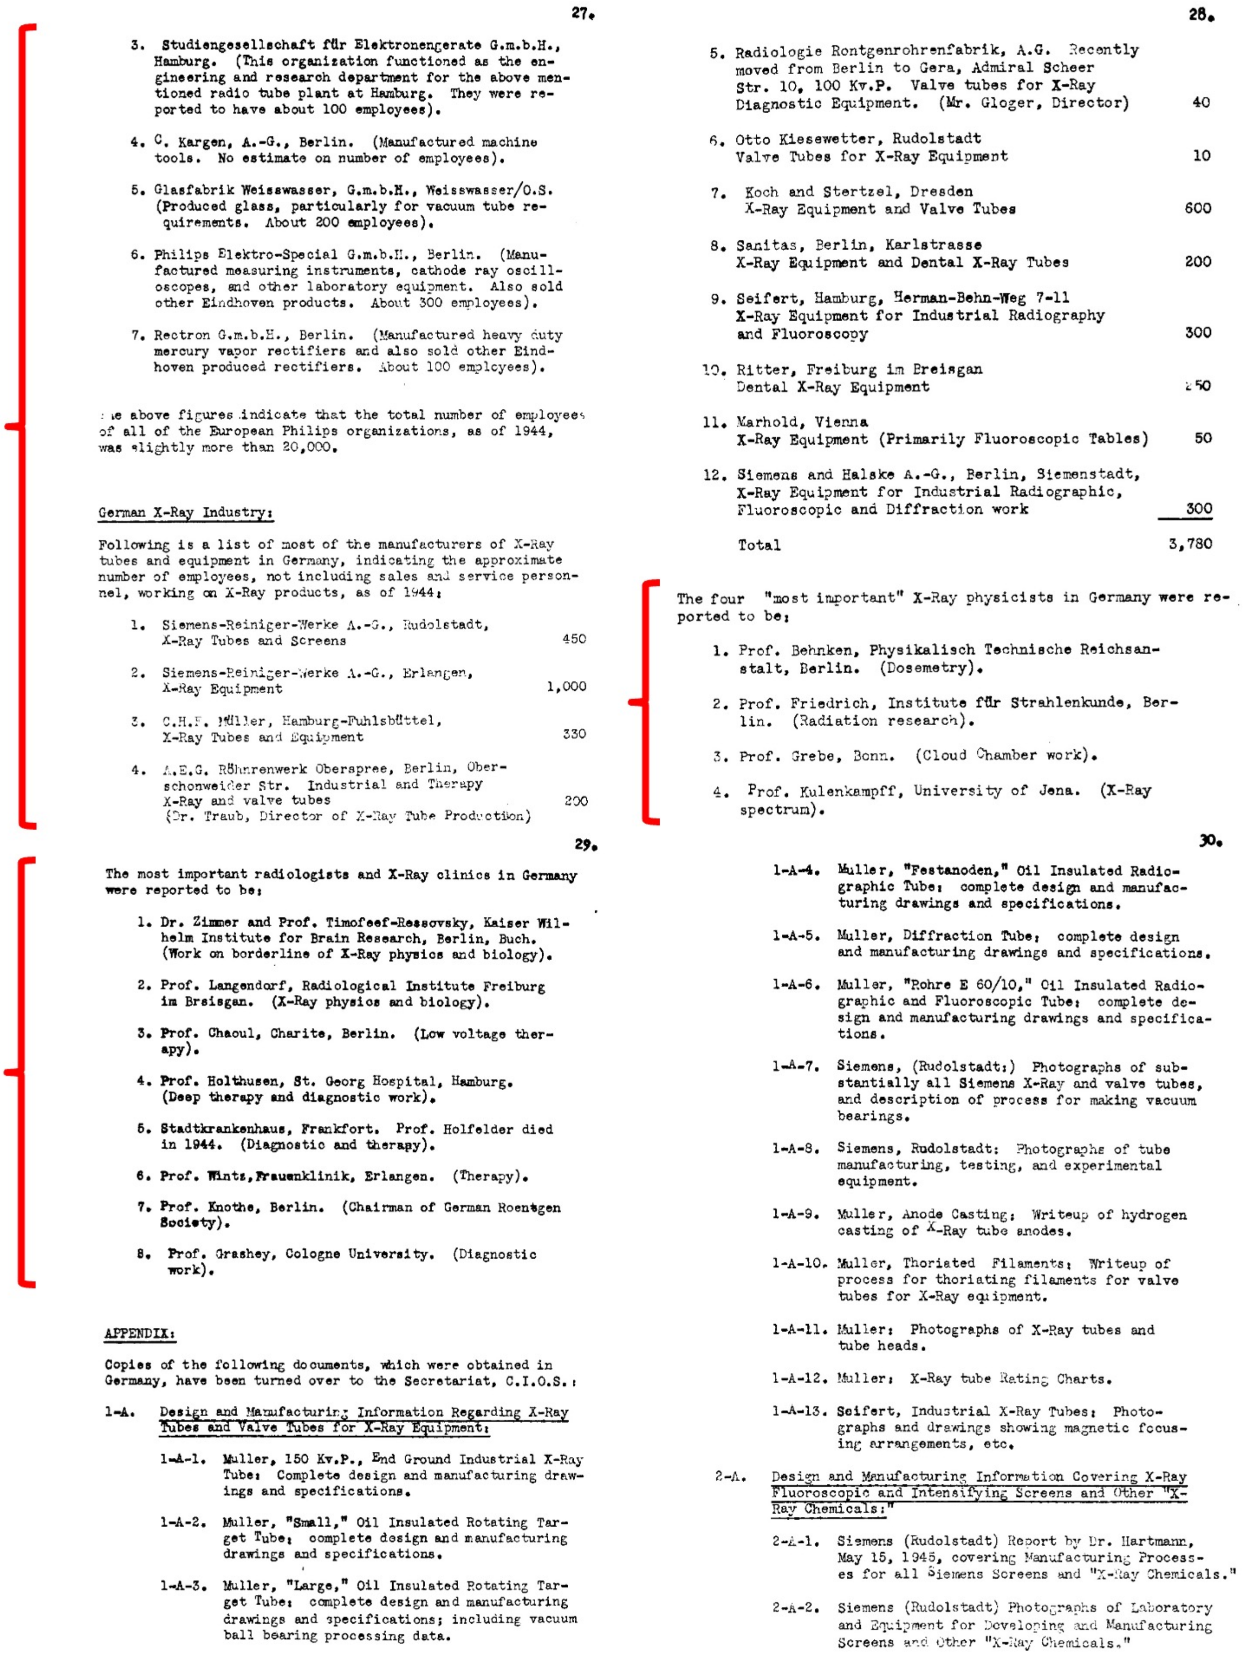
During the last part of 1944, the Eindhoven plant had about 15,000 employees. It was estimated that about 500 of these employees were working on X-Ray and other electro-medical equipment, 4,500 on airforce radio equipment, 5,000 on radio tubes, and 5,000 on incandescent lamps.

The Eindhoven plant not only produced substantially the same X-Ray tubes and equipment that were being manufactured at the Muller plant, but also higher powered transformer and control units, tube stands, tilting tables, quartz lamps, short wave diathermy equipment, etc.

Following is a list of the organizations which were reported to be owned and controlled by Philips as of 1944:

1. C. H. F. Muller Aktiengesellschaft, Hamburg. (Previously described in this report).
2. Philips Valvo-Werke G.m.b.H., Hamburg; also known as Radiorohrenfabrik G.m.b.H. (The Hamburg plant employed about 4,000 and manufactured radio tubes. This firm also had a plant in Aachen which produced radio sets, but this plant was destroyed by bombs in 1942. The sales office of this firm was in Berlin).

Figure D.446: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



27.

3. **Studiengesellschaft für Elektronengerate G.m.b.H., Hamburg.** (This organization functioned as the engineering and research department for the above mentioned radio tube plant at Hamburg. They were reported to have about 100 employees).
4. C. Kargen, A.-G., Berlin. (Manufactured machine tools. No estimate on number of employees).
5. Glasfabrik Weisswasser, G.m.b.H., Weisswasser/O.S. (Produced glass, particularly for vacuum tube requirements. About 200 employees).
6. Philips Elektro-Special G.m.b.H., Berlin. (Manufactured measuring instruments, cathode ray oscilloscopes, and other laboratory equipment. Also sold other Eindhoven products. About 300 employees).
7. Rectron G.m.b.H., Berlin. (Manufactured heavy duty mercury vapor rectifiers and also sold other Eindhoven produced rectifiers. About 100 employees).

The above figures indicate that the total number of employees of all of the European Philips organizations, as of 1944, was slightly more than 20,000.

German X-Ray Industry:

Following is a list of most of the manufacturers of X-Ray tubes and equipment in Germany, indicating the approximate number of employees, not including sales and service personnel, working on X-Ray products, as of 1944:

1.	Siemens-Reiniger-Werke A.-G., Rudolstadt, X-Ray Tubes and Screens	450
2.	Siemens-Reiniger-Werke A.-G., Erlangen, X-Ray Equipment	1,000
3.	C.H.F. Müller, Hamburg-Fuhlsbüttel, X-Ray Tubes and Equipment	330
4.	A.E.G. Röhrenwerk Oberspree, Berlin, Oberschonweider Str. Industrial and Therapy X-Ray and valve tubes (Dr. Traub, Director of X-Ray Tube Production)	200

28.

5.	Radiologie Rontgenrohrenfabrik, A.G. Recently moved from Berlin to Gera, Admiral Scheer Str. 10, 100 Kv.P. Valve tubes for X-Ray Diagnostic Equipment. (Mr. Gloger, Director)	40
6.	Otto Kiesewetter, Rudolstadt Valve Tubes for X-Ray Equipment	10
7.	Koch and Stertzel, Dresden X-Ray Equipment and Valve Tubes	600
8.	Sanitas, Berlin, Karlstrasse X-Ray Equipment and Dental X-Ray Tubes	200
9.	Seifert, Hamburg, Herman-Behn-Weg 7-11 X-Ray Equipment for Industrial Radiography and Fluoroscopy	300
10.	Ritter, Freiburg im Breisgan Dental X-Ray Equipment	250
11.	Marhold, Vienna X-Ray Equipment (Primarily Fluoroscopic Tables)	50
12.	Siemens and Halske A.-G., Berlin, Siemenstadt, X-Ray Equipment for Industrial Radiographic, Fluoroscopic and Diffraction work	300
	Total	3,780

The four "most important" X-Ray physicists in Germany were reported to be:

1. Prof. Behnken, Physikalisch Technische Reichsanstalt, Berlin. (Dosemetry).
2. Prof. Friedrich, Institute für Strahlenkunde, Berlin. (Radiation research).
3. Prof. Grebe, Bonn. (Cloud Chamber work).
4. Prof. Kulenkampff, University of Jena. (X-Ray spectrum).

29.

The most important radiologists and X-Ray clinics in Germany were reported to be:

1. Dr. Zimmer and Prof. Timofeef-Ressovsky, Kaiser Wilhelm Institute for Brain Research, Berlin, Buch. (Work on borderline of X-Ray physics and biology).
2. Prof. Langendorf, Radiological Institute Freiburg im Breisgan. (X-Ray physics and biology).
3. Prof. Chaoul, Charite, Berlin. (Low voltage therapy).
4. Prof. Holthusen, St. Georg Hospital, Hamburg. (Deep therapy and diagnostic work).
5. Stadtkrankenhaus, Frankfort. Prof. Holfelder died in 1944. (Diagnostic and therapy).
6. Prof. Wintz, Frauenklinik, Erlangen. (Therapy).
7. Prof. Knothe, Berlin. (Chairman of German Roentgen Society).
8. Prof. Grashey, Cologne University. (Diagnostic work).

APPENDIX:

Copies of the following documents, which were obtained in Germany, have been turned over to the Secretariat, C.I.O.S.:

1-A. Design and Manufacturing Information Regarding X-Ray Tubes and Valve Tubes for X-Ray Equipment:

1-A-1. Muller, 150 Kv.P., End Ground Industrial X-Ray Tube: Complete design and manufacturing drawings and specifications.

1-A-2. Muller, "Small," Oil Insulated Rotating Target Tube; complete design and manufacturing drawings and specifications.

1-A-3. Muller, "Large," Oil Insulated Rotating Target Tube; complete design and manufacturing drawings and specifications; including vacuum ball bearing processing data.

30.

1-A-4. Muller, "Festanoden," Oil Insulated Radiographic Tube; complete design and manufacturing drawings and specifications.

1-A-5. Muller, Diffraction Tube; complete design and manufacturing drawings and specifications.

1-A-6. Muller, "Rohre E 60/10," Oil Insulated Radiographic and Fluoroscopic Tube; complete design and manufacturing drawings and specifications.

1-A-7. Siemens, (Rudolstadt:) Photographs of substantially all Siemens X-Ray and valve tubes, and description of process for making vacuum bearings.

1-A-8. Siemens, Rudolstadt: Photographs of tube manufacturing, testing, and experimental equipment.

1-A-9. Muller, Anode Casting: Writeup of hydrogen casting of X-Ray tube anodes.

1-A-10. Muller, Thoriated Filaments; Writeup of process for thoriating filaments for valve tubes for X-Ray equipment.

1-A-11. Muller: Photographs of X-Ray tubes and tube heads.

1-A-12. Muller: X-Ray tube Rating Charts.

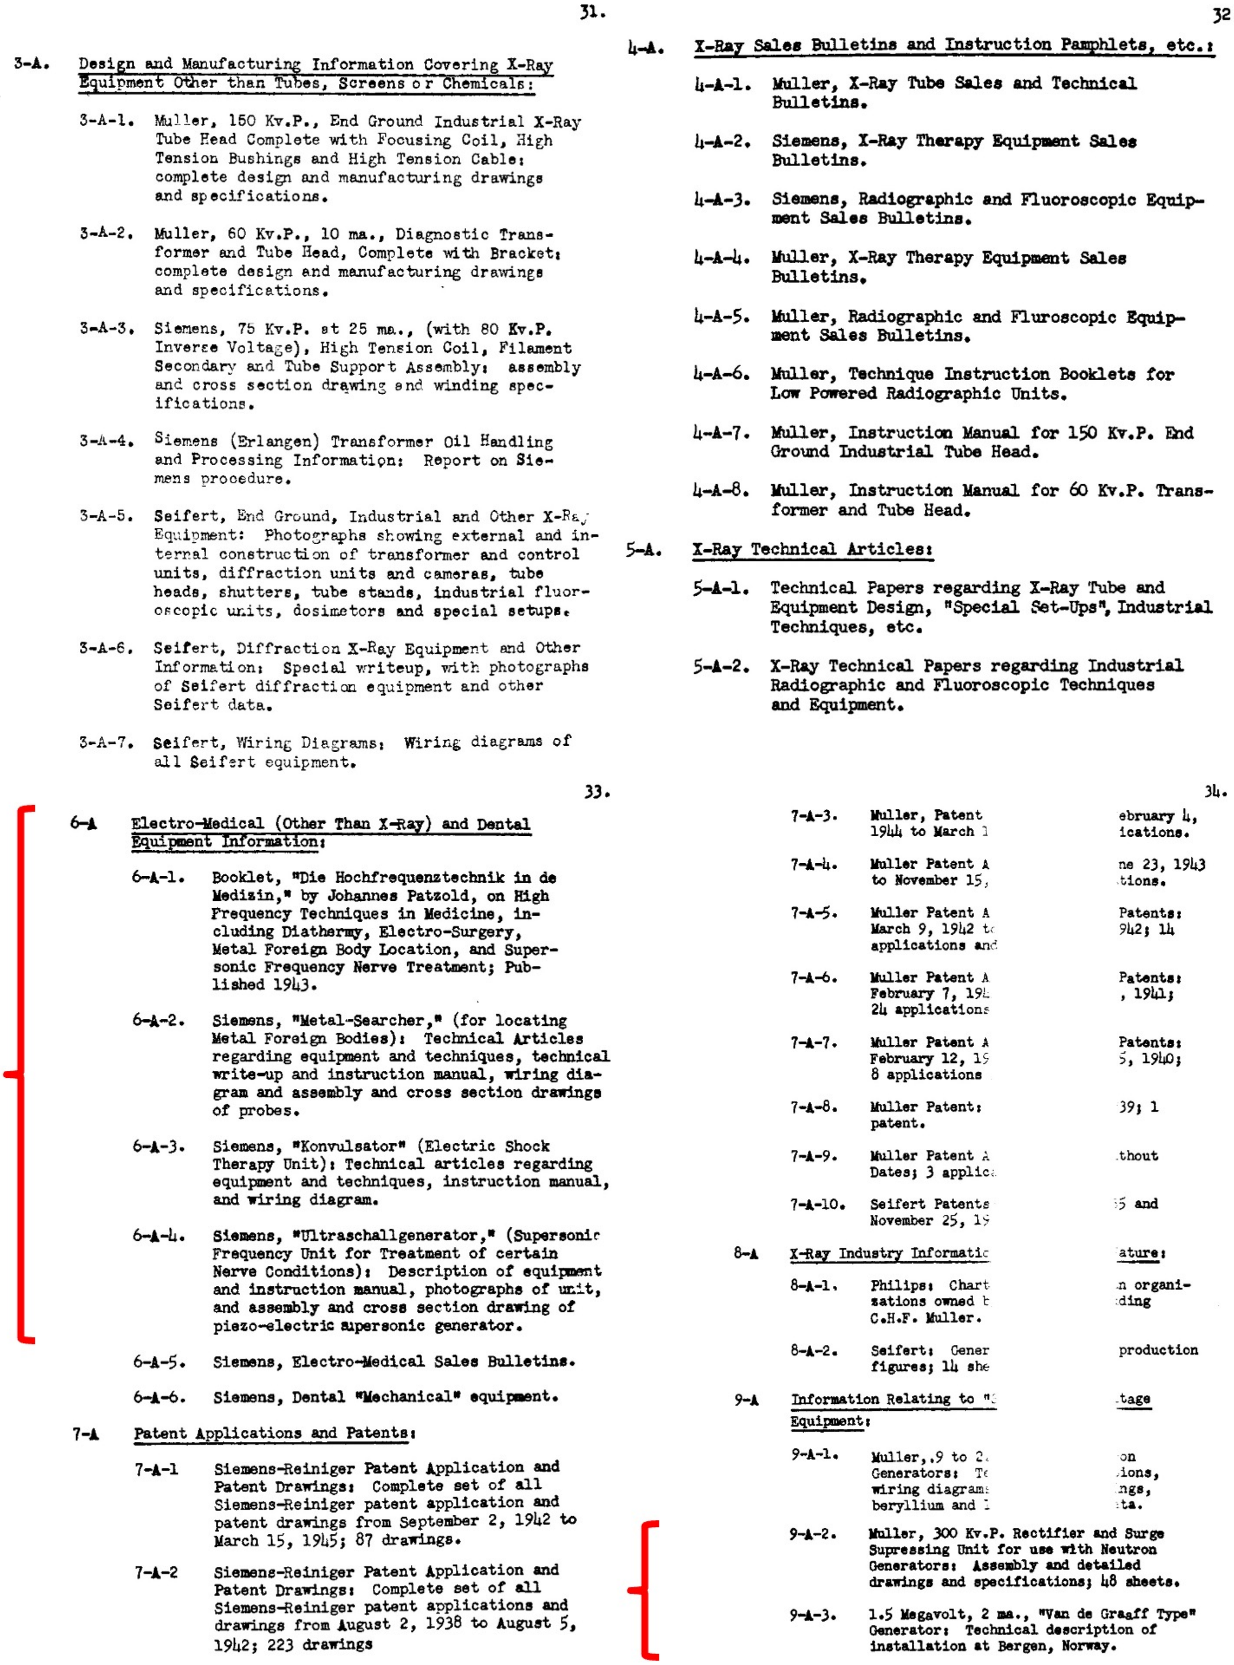
1-A-13. Seifert, Industrial X-Ray Tubes: Photographs and drawings showing magnetic focusing arrangements, etc.

2-A. Design and Manufacturing Information Covering X-Ray Fluoroscopic and Intensifying Screens and Other "X-Ray Chemicals:"

2-A-1. Siemens (Rudolstadt) Report by Dr. Hartmann, May 15, 1945, covering Manufacturing Processes for all Siemens Screens and "X-Ray Chemicals."

2-A-2. Siemens (Rudolstadt) Photographs of Laboratory and Equipment for Developing and Manufacturing Screens and Other "X-Ray Chemicals."

Figure D.447: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.



31.

3-A. Design and Manufacturing Information Covering X-Ray Equipment Other than Tubes, Screens or Chemicals:

3-A-1. Muller, 150 Kv.P., End Ground Industrial X-Ray Tube Head Complete with Focusing Coil, High Tension Bushings and High Tension Cable: complete design and manufacturing drawings and specifications.

3-A-2. Muller, 60 Kv.P., 10 ma., Diagnostic Transformer and Tube Head, Complete with Bracket: complete design and manufacturing drawings and specifications.

3-A-3. Siemens, 75 Kv.P. at 25 ma., (with 80 Kv.P. Inverse Voltage), High Tension Coil, Filament Secondary and Tube Support Assembly: assembly and cross section drawing and winding specifications.

3-A-4. Siemens (Erlangen) Transformer Oil Handling and Processing Information: Report on Siemens procedure.

3-A-5. Seifert, End Ground, Industrial and Other X-Ray Equipment: Photographs showing external and internal construction of transformer and control units, diffraction units and cameras, tube heads, shutters, tube stands, industrial fluoroscopic units, dosimetors and special setups.

3-A-6. Seifert, Diffraction X-Ray Equipment and Other Information: Special writeup, with photographs of Seifert diffraction equipment and other Seifert data.

3-A-7. Seifert, Wiring Diagrams: Wiring diagrams of all Seifert equipment.

32.

4-A. X-Ray Sales Bulletins and Instruction Pamphlets, etc.:

4-A-1. Muller, X-Ray Tube Sales and Technical Bulletins.

4-A-2. Siemens, X-Ray Therapy Equipment Sales Bulletins.

4-A-3. Siemens, Radiographic and Fluoroscopic Equipment Sales Bulletins.

4-A-4. Muller, X-Ray Therapy Equipment Sales Bulletins.

4-A-5. Muller, Radiographic and Fluroscopic Equipment Sales Bulletins.

4-A-6. Muller, Technique Instruction Booklets for Low Powered Radiographic Units.

4-A-7. Muller, Instruction Manual for 150 Kv.P. End Ground Industrial Tube Head.

4-A-8. Muller, Instruction Manual for 60 Kv.P. Transformer and Tube Head.

5-A. X-Ray Technical Articles:

5-A-1. Technical Papers regarding X-Ray Tube and Equipment Design, "Special Set-Ups", Industrial Techniques, etc.

5-A-2. X-Ray Technical Papers regarding Industrial Radiographic and Fluoroscopic Techniques and Equipment.

33.

6-A Electro-Medical (Other Than X-Ray) and Dental Equipment Information:

6-A-1. Booklet, "Die Hochfrequenztechnik in de Medizin," by Johannes Patzold, on High Frequency Techniques in Medicine, including Diathermy, Electro-Surgery, Metal Foreign Body Location, and Supersonic Frequency Nerve Treatment; Published 1943.

6-A-2. Siemens, "Metal-Searcher," (for locating Metal Foreign Bodies): Technical Articles regarding equipment and techniques, technical write-up and instruction manual, wiring diagram and assembly and cross section drawings of probes.

6-A-3. Siemens, "Konvulsator" (Electric Shock Therapy Unit): Technical articles regarding equipment and techniques, instruction manual, and wiring diagram.

6-A-4. Siemens, "Ultraschallgenerator," (Supersonic Frequency Unit for Treatment of certain Nerve Conditions): Description of equipment and instruction manual, photographs of unit, and assembly and cross section drawing of piezo-electric supersonic generator.

6-A-5. Siemens, Electro-Medical Sales Bulletins.

6-A-6. Siemens, Dental "Mechanical" equipment.

7-A Patent Applications and Patents:

7-A-1 Siemens-Reiniger Patent Application and Patent Drawings: Complete set of all Siemens-Reiniger patent application and patent drawings from September 2, 1942 to March 15, 1945; 87 drawings.

7-A-2 Siemens-Reiniger Patent Application and Patent Drawings: Complete set of all Siemens-Reiniger patent applications and drawings from August 2, 1938 to August 5, 1942; 223 drawings

34.

7-A-3. Muller, Patent ebruary 4,
1944 to March ications.

figures; 14 she

9-A Information Relating to " tage
Equipment:

9-A-1. Muller, .9 to 2 on
Generators: T ions,
wiring diagram ngs,
beryllium and ta.

9-A-2. Muller, 300 Kv.P. Rectifier and Surge Supressing Unit for use with Neutron Generators: Assembly and detailed drawings and specifications; 48 sheets.

9-A-3. 1.5 Megavolt, 2 ma., "Van de Graaff Type" Generator: Technical description of installation at Bergen, Norway.

Figure D.448: Caperton Horsley's report CIOS XXVIII-31, *Investigation of the X-Ray Industry in Germany*, states that wartime German companies produced high-voltage fusion neutron generators, betatrons, cyclotrons, color-changing temperature-sensitive paint, a wide variety of highly advanced medical equipment, etc.

[Caperton Horsley (U.S., 1903–1988) was an expert on X-ray tubes who worked for several U.S. medical equipment companies. As a civilian investigator in Germany after the war, he found:

- "The names and addresses of a number of physicists who have recently been doing work on isotope separation."
- "The location and general description of the most important Betatron, Cyclotron, Van de Graaff generator, and mass spectrograph installations in Germany and territory that has been occupied by the Germans." These particle accelerator sites all over German-controlled territory could have been useful for electronuclear breeding.
- High-voltage fusion neutron generators, suitable for use as neutron initiators in fission bombs, and more advanced than the neutron initiators that were being developed in the United States.

These were extremely important aspects of the German nuclear program that Leslie Groves's Alsos Mission failed (at least publicly) to discover.

Leslie Groves responded by censoring Caperton Horsley's reports and apparently reprimanding Horsley, who does not seem to have discussed the German nuclear work again after that.]

Monthly Intelligence Summary. July–August 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

X SECURITY

a. It came to the attention of this office that one Caperton B. HORSELY, a CIOS investigator, had conducted an investigation in Germany during the course of which he had obtained considerable information about betatrons. The CIOS evaluation report referring to the betatron information was distributed in regular channels but this office censored the detailed report and prevented the distribution of undesirable information in the final report.

The system in effect with CIOS for censorship of TA material was reviewed with the secretariat of that organization and measures were taken calculated to tighten TA security.

[Caperton Horsley's CIOS reports were censored by Leslie Groves's office because he discovered critical information regarding the German nuclear program. Where are the original, complete versions of his reports? Where is the other information he obtained, such as the names of German scientists doing isotope enrichment, or sites throughout German-controlled territory that were manufacturing or using particle accelerators?]

Nr: 71228 16 November 1946

February 46 your office in cable WAR 98071 approved that one of 3 betatrons being manufactured Erlangen, US Zone Germany, be sent to University of Goettingen on completion. This betatron originally ordered by Goettingen before collapse of Germany. We advised General Sibert of your recommendation. USFET and this office have always proceeded this a firm statement of MED policy.

Reference letter your office subject report of Major Hadlock, dated 27 September, para 3. Therein stated disposition of 3 betatrons being considered by your office with final disposition pending.

After months of red-tape, Goettingen betatron completed and ready for shipment. Conference being held by General Draper of OMGUS in Berlin 20 November re details of transfer. This office requested by General Draper to attend.

Request clarification of MED policy. Details should reach London by mid afternoon 19 November.

End

Date 8 Jan

Colonel S. B. Ritchie,
Research & Development Service,
Office, Chief of Ordnance,
Washington 25, D. C.

Dear Col. Ritchie:

It has been brought to my attention by Mr. Rennekamp, who was in Europe as part of the Research and Development Mission, that he had occasion to interview a scientist at the Siemens Halske plant in Nurenberg on various fire control matters.

At that time this individual spoke of his connection with the atomic bomb work being done in Germany. This subject was not pursued further since neither Mr. Rennekamp nor the scientist concerned were involved directly with the subject at hand.

It is felt however that reference to Mr. Rennekamp's report at the Siemens Halske plant will indicate the name of this scientist. The individual who performed the atomic bomb work for Germany is a close personal friend of this individual and further investigation may be warranted. The matter is being broached at this time since Mr. Rennekamp indicates that current press releases seem to substantiate the information divulged by the person interviewed.

This informal note is merely for the purpose of bringing this matter to your attention should you desire to have the matter pursued further.

Sincerely,

Louis Rossetto

Col Ritchie:

Attached is Mr. Rennekamp's report. It does not give the name of the atomic bomb specialist.

However, I am quite certain that the man in question was Dr. Steenbeck. He moved from Berlin — Siemens Schuckert Werke, to their other plant — Siemens Reiniger, at Erlangen, near Nurnberg. He was the best man in Germany on atomic bombs and the cyclotron, according to our interrogation of top scientists at Siemens-Halske and Siemens-Schuckert Werke. Berlin.

Geology

He, ~~and~~ his papers and all his eqpt went to Russia. The Russians took over the Reiniger Plant, officially the very day we were talking to ~~Mr.~~ Dr. Benkert, Tech. Director, in Berlin. He showed Capt. Randell + myself the letter. c. H.c

Subject Neth. Atomic Research (Nation reported on) - Philips Electric Laboratories (Main title as per index guide) (Subtitles) (Make separate report for each title)

BRIEF. (Here enter careful summary of report, containing substance succinctly stated; include important facts, names, places, dates, etc.)

1. Netherlands Press Agency release dated Eindhoven, 7 Dec. 1945 reads as follows:

"Dutch scientists can produce atom bombs within a year", Dr. HEYN, who specializes in atomic research at Philips laboratories here, told ANEP yesterday.

"The American professors now visiting Holland were amazed at the extensive atomic research carried out at Philips when they were told of it during a visit they made to the firm's laboratories recently," Dr. Heyn added.

A cyclotron, the apparatus used for splitting the atom, weighing 250 tons and second only in size to that now being made in California, was shown to the visitors. This cyclotron, which will shortly be completed, was built during the German occupation, with "Wehrmacht" materials, without rousing German suspicion.

Dr. Heyn said that the Germans had repeatedly attempted to use the Philips laboratories for atomic research, but received no cooperation from Philips scientists.

Dr. Heyn recalled that Philips had also built apparatus for the Rutherford Laboratory at Cambridge, and for the Broglie Laboratories in Paris. Numerous new transmutations had been made, for instance, in 1938 gold was made from quicksilver.

"The Philips cyclotron is twice as big as the one we have at Massachussetts Institute", said Dr. Francis W. SEARS, Professor of Physics at the Massachussetts Institute of Technology in an exclusive interview with ANEP today.

He and Dr. Paul R. GLEASON, head of the Physics Department of Colgate University, were among the American visitors who went over the research laboratories at Philips.

N.A. Comment: NAVTECHMISEU personnel has been in constant contact with Philips - Eindhoven Laboratories since liberation in 1944. It is assumed full reports have been rendered through NavTechMisEu channels.

Figure D.455: D. Frothingham. 13 December 1945. Subject: Neth. Atomic Research—Philips Electric Laboratories [NARA RG 77, Entry UD-22A, Box 173, Folder 50.20. Netherlands: Research].

Hewlett Thebaud. 2 February 1946. France Ordnance Atomic Bombs. [**NARA RG 38, Entry 98C, Box 9, Folder TSC # 2601–2700**]

Information has been received from what are believed to be thoroughly reliable sources that during the German occupation of Holland, the Dutch constructed a cyclotron at the Headquarters of the Philips Lamp Works at Eindhoven, Holland.

The cyclotron was built from copper and other metals allocated to the German Army, yet its construction was so cleverly concealed from the Germans as never to have been made known to them.

There is no evidence of any atomic research in connection with the cyclotron. Work is now progressing in the television field and a larger screen model is now in the process of demonstration.

[It seems highly unlikely that a German-occupied Dutch factory would spontaneously decide to build a cyclotron for themselves using misappropriate German materials. Far more likely is that the cyclotron was built by the Dutch factory under contract to the German Army, but not delivered before the end of the war. This appears to be another example of the abundance of particle accelerators that were being produced and utilized for high-priority but unspecified purposes during the final years of the Third Reich.]

Air Raid, Sabotage Held Up Nazi Work on Atomic Bomb. *Paducah Sun Democrat* (Paducah, Kentucky) 23 August 1945.

PRAGUE, Aug. 23—(AP)—A shattering American air raid, Czech sabotage and an accident frustrated German experiments in Czechoslovakia seeking to develop an atomic bomb, newspaper accounts said here today.

A German engineer named Eisenbeck worked with the problem of releasing atomic energy in a radio plant at Vysocany, the accounts said. A blast and fire at the plant in 1943 followed by an American raid halted work soon after the plant resumed operations.

Some mysterious apparatus was dispatched to the Imperial Research Institute in Berlin, but Czech workers believed they managed to damage the delicate mechanism before it was shipped, the stories said.

[“Eisenbeck” was probably W. Isenbeck (German, 1912–19??). After the war, he worked on particle accelerators and nuclear/particle physics at Karlsruhe and CERN.

The “American raid” may refer to a U.S. air raid on the Prague area that occurred on 25 March 1945. If that raid was at least in part due to this nuclear work, it indicates both that Germany possessed a potentially threatening nuclear weapons program up to the end of the war, and that the United States government was keenly aware of that fact.

The nuclear-related work mentioned in this article was probably the construction of cyclotrons or parts for cyclotrons. Cyclotron components are known to have been manufactured during the war at the Marconi Radioslavia plant in the Prague Vysočany neighborhood (mentioned here), at the Volman plant in Čelákovice near Prague, and potentially at other locations in Czech territory. Cyclotrons could have been directly useful for an electronuclear breeding program to produce plutonium-239 or uranium-233. With suitable design modifications, they could also have been useful for electromagnetic separation of uranium-235 from uranium-238.

Versions of this same story also appeared in a number of other newspapers, such as:

Amarillo Daily News (Amarillo, Texas) 23 August 1945, p. 12.

Democrat and Chronicle (Rochester, New York) 23 August 1945, p. 20.

Morning Herald (Uniontown, Pennsylvania) 23 August 1945, p. 9.

Somerset Daily American (Somerset, Pennsylvania) 23 August 1945, p. 5.

Daily Mail 24 August 1945, p. 1.]

[To aid in visualizing the locations mentioned in this document and the following several documents, see p. 2098.

Note that this and the following messages to and from Prague involve very high-level U.S. military officials responsible for air and nuclear defense:

General of the Army Henry H. Arnold, Commanding General of the Army Air Forces.

Major General Leslie Groves, Commanding General of the Manhattan Project for all nuclear-weapons-related work and intelligence.

Major General Clayton Bissell, who was Chief of Intelligence for the Army Air Forces.

Brigadier General John Edwin Hull, who was Head of the Operations Division, War Department, General Staff.]

Military Intelligence Division W.D.G.S., Military Attaché Report Czechoslovakia. Subject: Scientists Experimenting on Secret Weapons. I.G. No. 0403.0700. Prague. Report No. R-42. 2 October 1945. [NARA RG 319, Entry NM3-85M, Box 19, Folder 925256]

Source and degree of reliability: Czechoslovak Counter Intelligence Officer — A-3

1. In accordance with directions contained in War Department Cable No. 68418, of 24 September 1945, the following list of scientists, Czech and German, with their specialties and present status, is submitted.

2. a. the HÜTTIG GROUP is probably the most important. Professor HÜTTIG was the head of the Czechoslovak Radiological Institute during the Occupation; this is the only group which worked on practical application in warfare of the splitting of the atom. They are not known to have conducted any practical experiments, but they worked on the theory under the supervision of a German, Professor Dr. BRAUN, who has just been located in Czechoslovakia and is expected in PRAHA today's date, where he will be available to Czech authorities. In addition to the calculations for the atomic bomb, Professor HÜTTIG perfected a radar-disturbing paint for U-boats, a sample of which has been promised this office. Within the last few days a complete Cyclotron, which I understand is an apparatus used in the splitting of the atom, was found in the VOLMAN Factory at CELAKOVICE, Central Bohemia, and has been moved to PRAHA.

The HÜTTIG Group consists of:

Professor HÜTTIG, German, free but available to Czech authorities.

His principal assistant, Dr. [Heinrich Eduard] KAFKA, German, free but available to Czech authorities.

Professor Dr. ZACEK, Czech, free but available to Czech authorities.

Professor BIEHONEK, Czech, free but available to Czech authorities.
The two latter are subject to arrest at any time.

Professor Dr. PANZAKIEWITZ, a specialist on Measuring Devices, German, in protective custody.

Professor Dr. [Karl] KARAS, mathematician; he also worked on and presumably perfected a "Mother Rocket" or multiple rocket, German, in protective custody.

Professor Dr. v. MEYEREN, specialist on Measuring Devices, German, in protective custody.

Dr. SEDLACEK, Assistant to HÜTTIG, German, protective custody.

Dr. PAUL WENZEL, principal chemist of the HÜTTIG GROUP, German, protective custody.

An engineer named PSCHERA, assistant to HÜTTIG, German, protective custody.

Three engineers named BREUER, THEIMER and WAGENKNECHT, also HÜTTIG assistants, Germans, in protective custody.

Dr. GIESOLF, Dutch Collaborator, in protective custody, already exploited by American Technical Intelligence Team.

b. Next in importance are,

Dr. HELMAR FRANK, an expert on Infra-Red Rays; he is a German and in protective custody.

An engineer, GEORG GILLES, who worked on V weapons. He is a German, and in protective custody. It is understood that an agreement has been reached whereby GILLES will ultimately be released and turned over to American authorities to work for them, but this has not been definitively established.

Dr. ROHSMANN, expert on explosives, German, free, but available.

An engineer named NEUMANN, an expert on Ground Installation for V-3 and on the so-called "HAWAII" and "HAASE-GERÄTE", German, free but available.

Professor [Witold] WIECHOWSKI, an expert on mechanical details of the V-3; formerly worked in PEENEMÜNDE; German, free but available.

c. An engineer named KOSAK, German, voluntarily or otherwise left PRAHA to work for the Russians (see paragraph 4, Report R-32, this office, dated 30 September 1945).

d. The LEINWEBER GROUP, which worked on rockets of various kinds, consists of,

Engineer LEINWEBER, expert on Acoustic Rockets; German, in protective custody.

Engineer GÜNTHER, assistant to LEINWEBER, who also independently worked on Submarine Rockets; German, protective custody.

Engineer SALAMOUN, expert on "Waterfall" or "Cascade" [Wasserfall surface-to-air] Rockets; German, protective custody.

e. Two German engineers named BAUER and KÄSER, who are at liberty in LIBEREC where they have a small factory, are the inventors of a new system of rapid automotive propulsion. They are said to possess a number of world-widepatents; for the time being, they are being left alone by the Czech authorities.

3. All of the above can be made available at any time for interview.

AAGE WOLDIKE
Lt. Col GSC
Military Attaché

[See document photos on pp. 5510–5511.

This report stated that the Hüttig group was working on theoretical calculations for the atomic bomb, under the supervision of a "Professor Dr. Braun" who may have helped to coordinate their work with a larger German nuclear weapons program. Who was Braun? What organization was he from?

The Alsos Mission found reports from some members of the Hüttig group in the files of Walther Gerlach, the German Plenipotentiary for Nuclear Physics during the final stages of the war.

Note that the report mentioned a cyclotron that was produced in wartime Czechoslovakia; this cyclotron is also mentioned in subsequent documents.

Some of the engineers who worked on the "V-3" rocket are specifically identified here.

For more information on Helmar Frank, see pp. 1050–1072, 2756–2757, 5503, 5513, and 5549.

For more information on some of the other named scientists, see
https://dspace.cuni.cz/bitstream/handle/20.500.11956/47183/140006538.pdf.]

BIOS 871. *Work of Professor Hüttig on Ferromagnetic Substances for Use in Radar Camouflage.* p. 25.

(d) Prof. Dr. GUSTAV F. HÜTTING

Autobiography. H.12

G. F. Hüttig was born in Prague/Czechslovakia May 13th 1890. From 1907 he was studying technical chemistry in Prague, where he became 1912 Engineer and got 1913 the doctors degree of technical science. [...H]e became scientific collaborator of A. Hantzsch on the University of Leipzig. In 1914 he became Assistant in the institute of W. Biltz on the mining academy in Clausthal a. Harz in Hannover[...] In 1921 he became in Clausthal University teacher of inorganic and physical chemistry. From 1922–26 he was professor of inorganic, analytical and physical chemistry at the university of Jena. From 1926 till May 5th, 1945, he was Professor of inorganic and analytical chemistry at the German High Technical School in Prague and director of the institute. In the last years he was also Professor of the University of Prague[...] From 1929 on he was scientific collaborator and counsellor of the "Deutsche Gold- und Silberscheideanstalt" in Frankfurt a. Main.

Scientific Works.

The own research-works concern in the main point the following spheres: the knowledge of the chemical affinity especially its application on the chemistry of complexes, hydrates of salts, oxide-hydrates/hydroxides, active matters, stoichiometry, catalysis, mixed catalyzisers, reactions between solid bodies, system of reactions-types, powder-metallurgy production of aluminium from silicates, producing of matters with certain qualities and more. [...]

[illegible], SUBJECT: FOCKE Franz - Atomic Energy Research Scientist, [illegible]

Page 3 VOECKLABRUCK FIELD OFFICE

Subject claims that he started research work in the atomic energy field in 1920, using the laboratories of the Krizik Chemical firm at Bodenbach, CSR. Subject also stated that the main purpose of his work was to convert uranium ore and radium combinations to electrical energy and to accelerate the decomposition of uranium and radium. Subject also stated that in 1945 he had in his possession approximately 4 pounds of uranium valued at 20,000 Marks. Subject used this uranium in experiments to convert atomic energy to electrical energy for industrial purposes. Subject stated that on 12 June 1949 he wrote to the Los Alamos Atomic Research Commission offering his services, however, until the present time he has received no answer.

3. A check made of the files of the 430th CIC Detachment, Land Upper Austria Sub-Detachment revealed the following information:

On 1 [illegible] 1948, Subject wrote a letter to Gertrude K. [illegible], 18 Emily Avenue, Nutley 10, New Jersey, (see attached, I/P 8667, dated 18 April 1948). Intercept is quoted below:

"My research works made till now on the sphere of transmutation of atomic kernels: Since the year 1921 I have been engaged privately in works of transmutations of atomic kernels of heavy elements, when I at first had in view esp. to bring about a quicker decay of active elements such as radium combinations etc. There I intended to find a new way to effect the atomic decay with a smaller expense of power. For my works I used pitch blende (U_3O_8) from St. Joachimsthal in CSR and the uranium ore dye residues of the uranium manufacturers, from which I produced after the methods of Madame Curie, radium-barium chloride by means of fractionated crystallization. I subjected these products alone or mixed with or [illegible] by other substances to the influence of an electromagnetic high frequent voltaic arc. Source of current was an oscillatory aggregate for the generation of current with a necessary high apparent power and a high tension transformer for 150 KV, so that I could obtain high frequent electromagnetic oscillations. I partly worked also with higher temperatures, which I obtained by a fit arrangement of thermite powder. The presence of iron filings in the mass plays an important part. I also made a large number of series experiments; in the autumn of 1932 I happened to attain and atomic demolition with crystals of an element mixture uranyl [illegible] with radium-barium-chloride. The tension used was relatively low - it was 100 - 120 KV, the demolition of the mass weighing only

Informal Routing Slip

HEADQUARTERS
UNITED STATES FORCES IN AUSTRIA

SUBJECT: FOCKE, Franz - Atomic Energy Specialist

Number each message consecutively. Fill in all columns, authenticate message, draw a line across the page just below authentication. Use entire width of page. Use only for inter-office communication.

NO.	FROM	TO	DATE	MESSAGE
1.	ODDI Opns (IB-5)	430 CIC Opns	10 Oct 49	1. Reference SOI L/15518, MH-105, 25 July 1949, Voecklabruck Field Section, Subject as above. Subject is a very interesting case and one who requires careful evaluation. He has a better than average knowledge of atomic energy and it would seem impossibile to class him as peculiar or a crackpot. He has written his letters in such a manner that he has covered the entire field of nuclear research and experimentation, some sections of which have high intelligence value. The possibility that Subject may be a skilled intelligence agent casting out information with the intention that we will follow up our main points of interest cannot be overlooked. Soviet technical intelligence agents operate under the Soviet counter-intelligence agency and, as such, are inclined to use this type (counter intelligence) of approach to develop or guage our current intelligence interest in any particular field.

2. Therefore, the safest technique in handling Subject is to let him cool off, but to casually watch his interests and make every attempt to evaluate him as an individual. As the situation stands now, Subject could be classified as any of the following:

a. a crackpot who has read a lot about atomic energy. This impression may be due in part to errors in technical translation of Subject's letters.

b. A well-briefed Soviet technical intelligance agent. His statement about possession of 4 pounds of uranium valued at 20,000 Marks is also suspicious. Also, there was once a report of an atomic pile operated by Russians at Bodenbach, CSR, which we now believe to be false. Other suspicious items are:

(1) Writing of his experiments in the mail, knowing, or trying to determine if we are watching technical or scientific items of information through censorship.

(2). Subject's training (during which he admits he did not acquire a degree) and experience (consistently in the fields of cable construction and electrical engineering) nowhere indicate any work with physics or atom physics — a field in which capable and well-trained physicists frequently find themselves "over their heads".

CONFIDENTIAL

(3) If he had been a bona-fide atomic energy specialist, he would have worked with well-known scientists in Austria or CSR, or would have mentioned them as references without being questioned.

5-4843

Figure D.458: According to 1949 U.S. Army Counter Intelligence Corps interrogations of Franz Focke, a longtime employee at Bodenbach/Krizik, nuclear research began there no later than 1920, continued through World War II, and resulted in a fission reactor there that fell under Soviet control after the war [NARA RG 319, Entry A1-134B, Box ??, Folder XE065437 Focke, Franz]. The interrogators were skeptical about the reactor claim, but it is consistent with the large amount of other nuclear-related work at that same site (pp. 3987–3998).

The Puzzle of Podmokly. *Time.* 12 November 1945.

Had the atomic armaments race begun? In Moscow a writer for The New Times declared that reactionary forces in the U.S. were bent on "blackmailing humanity" by trying to keep the atomic bomb a U.S. property.

From western Czechoslovakia, where the Elbe river bursts through the Sudeten mountains into the flat meadow lands bordering Germany, came a different story.

Nestled in the mountains six miles from Podmokly was a vast underground factory, the Weser Works. In the first three months of liberation the Weser Works were quiet, deserted. Now they hummed with hidden activity. Czech and Russian security police kept close watch on the difficult mountain approaches.

The underground factory was a product of the war. When the Germans came to Podmokly (which they called Bodenbach) they seized the Krizik Works, Czechoslovakia's largest producer of copper wire, the area was rich in coal and hydroelectric power, and had excellent communication facilities. Later they imported French, Belgian and Russian laborers, and set them to work expanding the Krizik plants. Laboratories were built, buildings enlarged, new units erected. One of the new units was put underground, and was supersecret. It was known simply as "the Weser."

The Losing Race.

In time the first secret of the Weser became apparent. Its parent plant was producing V-weapons. But it also manufactured cyclotrons for atomic experimentation. As the Allies bombed German laboratories, the Weser shipped new cyclotrons to secret destinations in the Reich where Hitler's scientists were running a losing race with history. At least three cyclotrons were shipped in the last year and a half of war.

The retreating Germans left the Weser grounds littered with the fuselages, fins and working parts of V-bombs. In iron safes were plans for Vergeltungswaffe-4, said to be a giant, radio-controlled rocket capable of being fired from Prague to the Americas. The Germans also left parts of cyclotrons and other equipment for research in nuclear physics.

For a time the Russians showed no particular interest in the underground factory. Strangers wandered in & out at will. But the explosions over Hiroshima and Nagasaki brought a quick change. The security police moved in, and Germans who had worked in the factory were rounded up, put back to work. Former officials of the Krizik Works were kept out. In northern Bohemia the Russians took over the Jachymov mine, famed for its uranium deposits.

If the Weser's cyclotrons were what interested the Russians, Moscow was still in the experimental stage of atomic development. The U.S. had entered the production stage in 1943.

[The Weser and Krizik Works near Podmokly was a very large German weapons research, development, and production complex during the war (and had been founded long before, p. 953). It was reportedly involved in nuclear weapons work, advanced rockets, and other revolutionary innovations.

What exactly was the V-4 rocket?

Why did Weser/Krizik produce at least three cyclotrons (or maybe more) during the war?

Can all of the records from the Weser/Krizik complex be located in Russia and released?]

NO. 1 OF [illegible] COPIES, SERIES a

To : Major General Groves
From : Colonel Shuler
Subject: Atomic Bomb Research in Russian Zone of Czechoslovakia

16 Nov 45

Colonel Ernest W. GRUHN, ASF Int., forwarded this office a report submitted to JIOA by one T. M. ODARENKO. The report is dated 26 Oct 45 and is substantially as follows:

a. At the request of Dr. H. P. ROBERTSON, Chief of Scientific & Technological Branch of FIAT (Field Information Agency Technical), ODARENKO prepared this report covering his trips to Berlin, Czechoslovakia, and Austria to interview scientists engaged in "fundamental research work in chemistry and physics in order to gather the most complete information on the problem of the so-called radiation absorption material." Though without intending to explore the atomic physics field, he received information of direct bearing on it:

Intelligence

1) First direct information of Russian activity in this field came to him from one Otakar HORAK of Prague introduced to him as an officer of the Czech CIC by our M. A. to Prague, Lt. Col. WOLDIKE. HORAK volunteered to assist the U.S. authorities "upon recommendation of his highest authorities." WOLDIKE suggested that, inasmuch as technical intelligence in Czechoslovakia was not feasible, ODARENKO should use the services of HORAK who, however, has not proved of any value either because he didn't risk working with ODARENKO or didn't trust him.

2) HORAK did say that the Russians have

a) established a special research institution some distance east of Prague;

b) have engaged some sixty (60) scientists and a number of assistants to complete the work of atomic energy release; at this inst,

c) have placed at this group's disposal a fully equipped lab and a trial field. The lab is using a "highest-voltage generator"; but another section is working on a method not requiring neutron generators and the race is close. It was "confidentially expected that the problem would be solved before 'the snow comes down.'"

3) HORAK "bemoaned the fact" that the U.S. has no scientific representatives in Prague to whom he can report the progress of Russian scientific activities in Czechoslovakia because, on instructions from the "highest military Czechoslovakian authority" he was in position to give such representative all reports on the final accomplishments of Russian atomic research when completed.

4) ODARENKO was much impressed with the accuracy of HORAK's information about the location of certain German scientists "now in the American zone of occupation presumably Austria and with his knowledge of the progress of atomic research in Germany and Austria" before war's end. ODARENKO got the impression this information came to HORAK from Russian sources.

TOP SECRET

To : Major General Groves

16 Nov 45

From : Colonel Shuler

Subject: Atomic Bomb Research in Russian Zone of Czechoslovakia (CONT'D)

5) ODARENKO believes that Russia "is about ready to evolve some sort of atomic bomb." He bases this belief on the following:

a) In Berlin he heard the names of Drs. STEENBECK, BEWILOGUE, von ARDENNE, and THIESSEN, names he heard again in Prague and Vienna. In Vienna he talked with a Russian colonel who knows the locations of German scientists such as Profs. BOTHE, MATTAUCH, JUSTI, and Drs. STETTER and WAGNER, all nuclear physicists who, the colonel said, would be of great use to Russia and who, he thought, would eventually find their way there because the policy of the United States drives them away.

b) The Russians now have in their hands a 3-million volt mA generator built for the KWI for Biological Research and delivered to a mine in Stassfurt on the Elbe River, south of Magdeburg. KOCH & STERZEL, the builders, are capable of building larger ones and are located in the Russian zone.

6) ODARENKO believes that apparently, then, the Russians are well-equipped to get results and have the "driving motives" to do it. Indeed, if sixteen (16) men of Dr. Stetter's Institute (Thumersbach near Zell-am-See) think they can solve the problem in three to six months with a minimum of materials, a well-organized lab in Russia could do at least as well.

7) It might be of interest to the U. S. to know the progress of such work and the results of it and ODARENKO recommends some attempt be made to investigate the status and claims of HORAK. If he proves reliable, ODARENKO recommends his services be used.

8) He also recommends that question of these displaced German and Austrian scientists, who are anxious to carry on, be carefully considered so that they won't fall into the hands of the Russians.

3. The most important factors currently limiting increases in Soviet military power are shortages of (1) industrial facilities, and (2) competent scientists and technicians. The U.S.S.R. is making vigorous efforts to overcome the latter shortage by the intensive exploitation of German scientists and technicians. Unless the migration of important German scientists and technicians into the Soviet Zone is immediately stopped, we believe that the Soviets within a relatively short time may equal U.S. developments in the fields of atomic research and guided missiles and may be ahead of U.S. development in other fields of great military importance, including infra-red, television, and jet propulsion. In the field of atomic research, for example, we estimate that German assistance already has cut substantially, probably by several years, the time needed for the U.S.S.R. to achieve practical results. (See Appendix "C" for additional details).

4. Important German scientists and technicians in the U.S. Zone are steadily migrating openly or clandestinely into Soviet hands. The U.S.S.R. is offering such men employment under excellent conditions both in the Soviet Zone of Germany and in the U.S.S.R. Where Soviet offers have not been a sufficient inducement to German scientists and technicians to leave the U.S. Zone, the Soviets have secretly removed them by force. American visits to the Soviet Zone are, furthermore, strictly limited to a particular purpose and are permitted only with Soviet escort to see that the mission authorized is strictly adhered to. Departure of German scientists and technicians from the Soviet Zone is apparently limited only to those Germans for whom the U.S.S.R is certain it will have no further use.

5. Virtually every important German laboratory, research establishment, or factory in the Soviet Zone concerned with new devices, not bombed out, is either in full operation or has been transferred to the U.S.S.R. with all its key personnel. The Soviets already have acquired technical knowledge, equipment, and personnel from the Germans which should eventually enable them not only to duplicate many important German developments, but also to continue along the lines of German research. There is no doubt, however, that the continued recruiting by the Soviets of large numbers of German scientists and technicians from outside the Soviet Zone will accelerate materially the results to be obtained, as well as deny them to the United States.

6. A comprehensive list of important German scientists and technicians in the U.S. Zone, their technical competence, and the size and composition of their families has not been compiled. Such a list is necessary to determine the capabilities of these Germans, estimate the specific effort their continued denial to the U.S.S.R. would have on Soviet scientific and technical progress and to determine what, if any, long-range plans are appropriate. Such a list would also be of assistance to the War and Navy Departments in determining what German scientists and technicians should be exploited for military purposes in the United States. It would be desirable also to have available in the U.S. accurate information regarding Germans whom government agencies other than the War and Navy Departments might desire to exploit for non-military purposes. [...]

APPENDIX “C”

U.S.S.R. EXPLOITATION OF GERMAN SCIENTISTS AND TECHNICIANS

1. Interrogation of qualified German personnel both in Europe and this country, as well as numerous intelligence reports, all indicate that long-range exploitation of German scientific and technical personnel and facilities is both thorough and intelligent throughout the Soviet Zone. Briefly the situation in some fields is:

a. Atomic research: The 7 top men working on atomic research in Germany were: Prof. HEISENBERG, Prof. HERTZ, Baron VON ARDENNE, Prof. BOTHE, Prof. STETTER, Dr. GERLACH, and Prof. BEWILOGUA [Ludwig Bewilogua, wartime expert on uranium piles and low temperature physics at the Kaiser Wilhelm Institute for Physics in Berlin]. Of these HERTZ, BEWILOGUA, VON ARDENNE, and BOTHE (Formerly in the U.S. Zone) are now working for the U.S.S.R. with many of their assistants. Practically the entire staff of the German “URANMOTOR” Project at KRIZIK [part of the Weser-Werke complex near Podmokly] in Czechoslovakia under Prof. HUETTIG is working for the U.S.S.R., so are large numbers of the staff of the Kaiser Wilhelm Institute connected with atomic research.

Still in the U.S. Zone at Zell-Am-See are an important group of German atomic scientists under Dr. STETTER and Prof. MATTAUCH. Tempted by alluring Soviet offers, this group is drifting one by one into Soviet employ.

b. Infra-red and television. Many of Germany’s finest factories and engineers in the field of electronics are now in Soviet hands. Of special important are Dr. STUETZER, formerly Reich Plenipotentiary for High Frequency Research, and Dr. STEIMEL of TELEFUNKEN. Among the many important plants that have fallen intact into Soviet hands are several plants of BLAUPUNKT and FERNSEH, outstanding manufacturers of infra-red and television equipment. There is little doubt that in these fields, German developments were ahead of those in other countries. [...]

c. Guided Missiles. A number of the best men in this field, including such men as Prof. VON BRAUN and Prof. WAGNER are at present in this country. Prof. KRAMER is at present in French hands, but they too will be the object of solicitation by the U.S.S.R. on their eventual return to Germany. Whereas the Soviets transferred the Kaiser Wilhelm Institutes at LICHTERFELDE and LANKWITZ to the Soviet Union, with all the available equipment and personnel, and control the research and testing establishments at PEENEMUENDE, BORNHOLM, and DRESDEN, they still lack the best scientists in the guided missiles fields. Hence, their continuing efforts to obtain the services of such scientists outside the Soviet zone.

d. Aircraft research and manufacturing establishments. Aircraft research establishments and engineers already in Soviet hands include [...]

[See document photos on pp. 3993–3996.

Note statements such as: "unless the migration of important German scientists and technicians into the Soviet Zone is immediately stopped, we believe that the Soviets within a relatively short time may equal U.S. developments in the fields of atomic research," and "in the field of atomic research... German assistance already has cut substantially, probably by several years, the time needed for the U.S.S.R. to achieve practical results." This once-top-secret report of the U.S. Joint Intelligence Committee seems to acknowledge that wartime German scientists had knowledge and capabilities equal to U.S. developments in the field of atomic research, by stating that those scientists had the ability to rapidly confer such knowledge and capabilities to the postwar U.S.S.R.

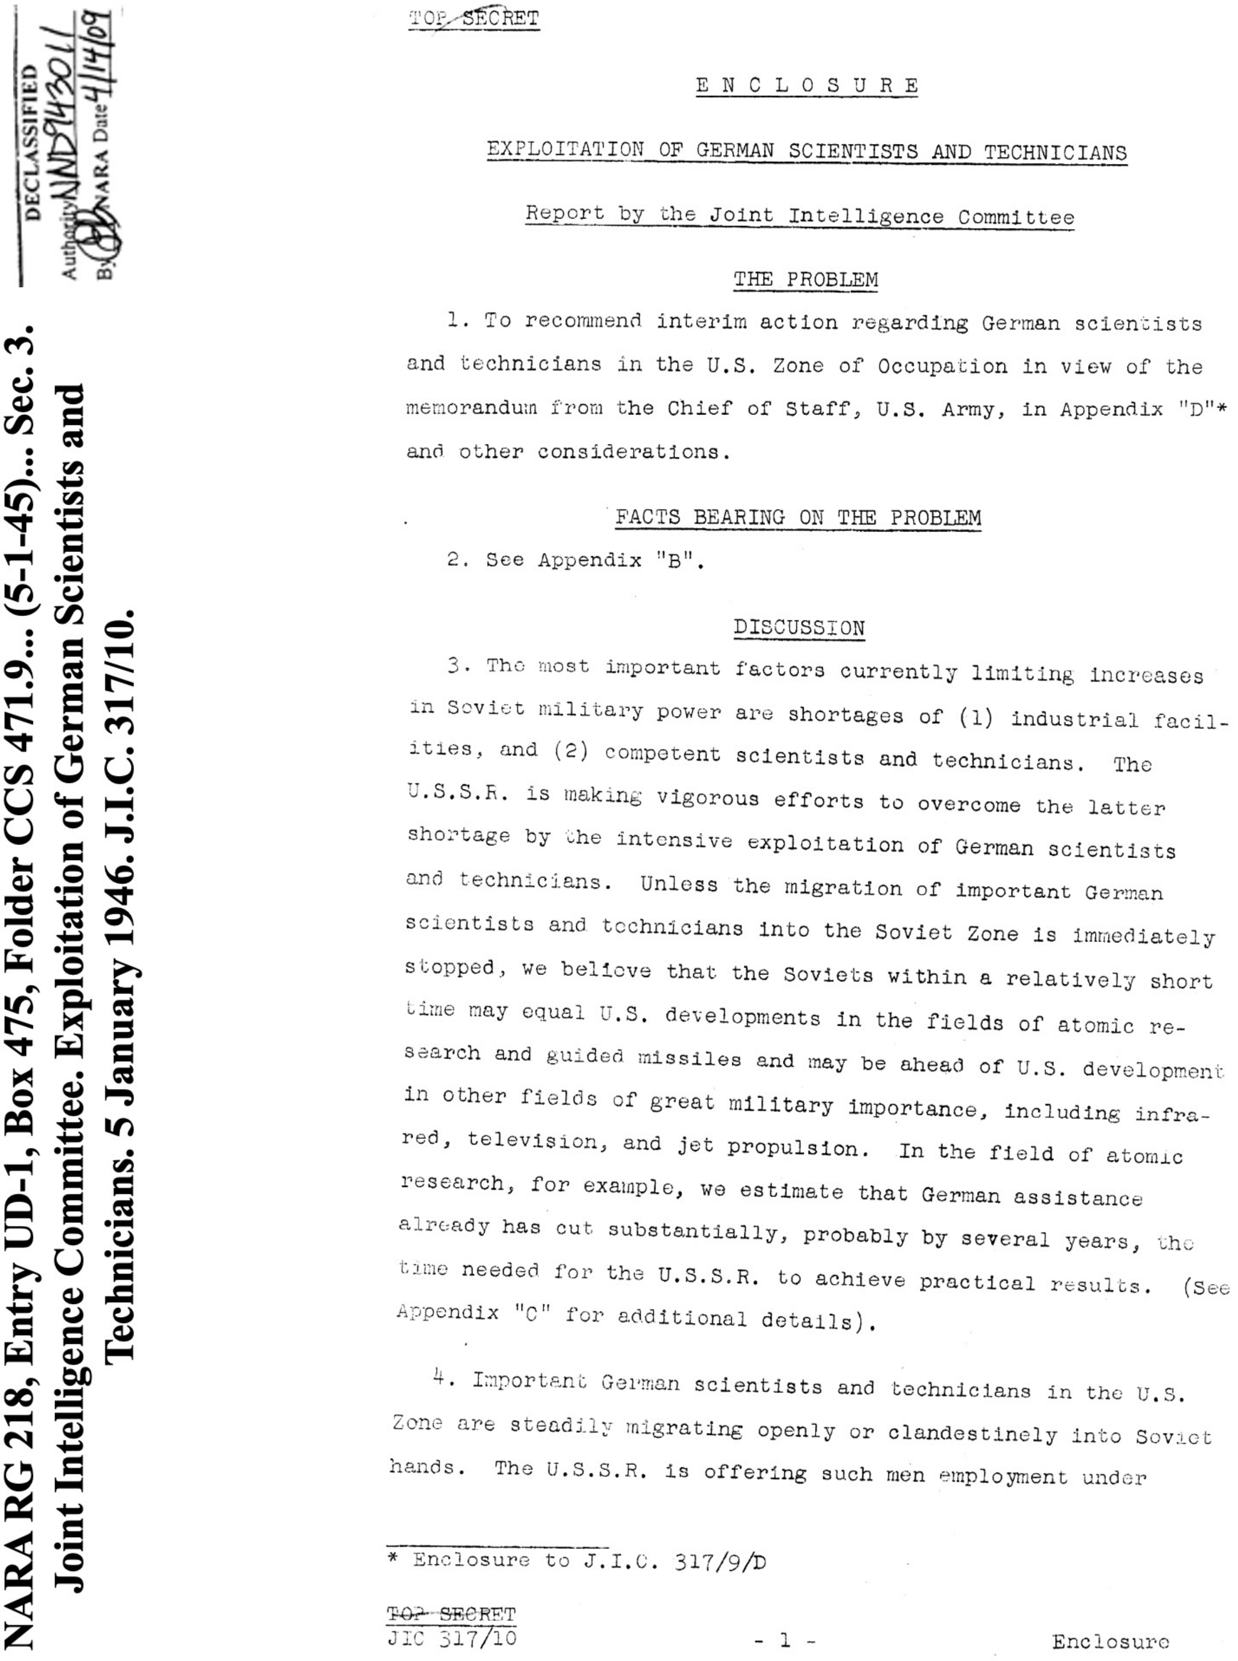
The report appears to acknowledge that wartime German knowledge and accomplishments in missiles, electronics, and jet aircraft significantly surpassed any non-German-assisted U.S. or Soviet programs in those areas.

What exactly did Ludwig Bewilogua accomplish in nuclear physics during and after the war? Where are the records on him and all of his work? He is listed here alongside Werner Heisenberg and Walther Gerlach, yet he and his work are almost unknown. See also p. 5059.

Gustav Hertz and Manfred von Ardenne were generously rewarded by Stalin for their contributions to the development of the Soviet atomic bomb. What all did they accomplish in Germany during the war? What information about their wartime accomplishments reached the Soviets and made them so eager to find and employ Hertz and von Ardenne? What exactly did they do for the Soviet program?

What was "the German 'URANMOTOR' Project" at Krizik, which had an "entire staff"?

What exactly were all the wartime and postwar research and development projects at the Krizik-Werke/Weser-Werke complex near Podmokly?]



NARA RG 218, Entry UD-1, Box 475, Folder CCS 471.9... (5-1-45)... Sec. 3. Joint Intelligence Committee. Exploitation of German Scientists and Technicians. 5 January 1946. J.I.C. 317/10.

together with documents and equipment were removed to Moscow after the fall of Vienna for continued work in the field of jet propulsion (ram jets). Soviet needs for qualified personnel in this field also are stressed by their continued efforts to recruit such personnel outside the Soviet Zone.

Figure D.464: Joint Intelligence Committee. Exploitation of German Scientists and Technicians. 5 January 1946. J.I.C. 317/10. [NARA RG 218, Entry UD-1, Box 475, Folder CCS 471.9... (5-1-45)... Sec. 3]

Vladimir L. Rychly. Report No. 2655: Report on Visit to Czechoslovakia. 11 February 1946. [NARA RG 38, Entry 98C, Box 9, Folder TSC # 2601–2700]

A. Between 3 January and 22 January, arrangements were made with the Czech'k General Staff to visit a number of plants that had been working for the German Navy during the war. Contact was made with this Staff through the British and U.S. Military Attachés who introduced me to Gen. BOCEK. The Czech authorities granted the permission but informed me that I would have to be escorted throughout by the Czech Secret Police (O.B.Z.). The plants visited were the following:

1. C.S.R. ZBROJOVKA at BRNO (Moravia) [formerly Waffenwerke-Brünn]. This firm has in all some eight plants in a radius of 70 Klms of BRNO. [...] Also removed [by the Russian Tech Control Commission] were all documents, drawings and a number of leading technicians.

2. PRVNI PRNENSKA STROJIRNA, BRNO (Moravia). [...] From this plant all documents were removed by the Russians, but no further work was carried out under their supervision.

3. BATA, ZLIN (Moravia). [...] Rubber for experimental [anti-sonar and/or anti-radar stealth] coverings of U-boat hulls. [...]

4. ZIKMUND-CHEMA at LUTIN (Moravia). [...] All documents and valuable machinery were removed by the Russians who, however, evacuated none of the technicians and scientists.

5. STEIN and SPOL at BRNO (Moravia). [...] Everything of interest was removed by the Russians.

6. SCHMIDDING at PODMOKLY (Bohemia). [...] By October 1945 the Russians stopped production, removed the completed torpedoes and other weapons, duplicates of all documents and number of German engineers to Russia.

7. WESERWERKE at DECIN (Teschen) (Bohemia). A lot of inaccurate reports have been circulated about the work carried on in the vast underground workshops of this plant. It has been reported that cyclotrons were manufactured and that in laboratories work was being carried out on atom smashing in conjunction with uranium isotope 235.

In actual fact the following work was carried out: production of V-1 and V-2. 55mm rockets. Schlange. Wespe. 30mm pneumatic cannon. Remote control rockets.

This plant was very strictly guarded until 1 December 1945, and it is thought that German technicians were still employed there up to that date. The plant has now been evacuated.

8. A.E.G. at BEDRICHOV (Bohemia). Manufactured F.B. Zielsuchgeraet. Pfau. Amsel. Ida 105 mine, accoustic, induction and reacting to change in water pressure. V-1 and V-2 fuses. The completed V-4. Lichtspiegelanlage.

The German scientists Pfister and Bakes, with whom I had the opportunity to speak, and some 22 other German scientists are still working on the development of the above under Czech supervision for the Russians. The program on which this firm is still engaged is much more extensive than that listed above. Pfister tried to pass me a copy of the complete program of work, but this was seized from my hand by one of the O.B.Z. officials present.

The O.B.Z. official promised that I should obtain a copy of this program in Prague. On arrival there General Bocek gave orders for it to be surrendered to me, but this got to the ears of Colonel Reicin, the right hand man of General Svoboda, who forbade the authorities to let me have a copy.

Both Pfister and Bakes seemed most keen to be of assistance to us.

9. VOLMAN at CELAKOVICE (Bohemia). Manufactured 3 cyclotrons that were removed to Russia. No work was proceeding in the factory.

10. CESKO-MORAVSKA. KOLBEN-DANEK at SLANY and PRAGUE (Bohemia). [...] This plant was bombed out entirely and as far as is known the Russians removed nothing. [...]

11. HAVEILKA PRAGUE (Bohemia). Manufactured bridge superstructures and conning towers for U-boat types XXI, XXIII, and XXVI W. [...]

The chief engineer of the firm carried out a tirade against the management of the works in my presence and was there and then removed by the O.B.Z.

12. ASKANIA PRAGUE (Bohemia). Works in Prague were bombed out. No permission was granted to see the other Askania works which were reported to me by a friendly major of the Czech General Staff as being inaccessible to Czechs and under Russian control.

B. Further information was obtained about a number of firms by unofficial visits and by enquiries in the right quarter.

1. Jet Propulsion laboratory at Turnov (Bohemia). This was cleaned out by the Russians in October or November 1945, and the scientists including Germans were removed by the Russians.

2. Radium production plant at Jachymov (Bohemia). The following information about this plant was given by a secretary in the Ministry of Mines in Prague who will produce a detailed report of work going on in this mine. Since 1863 uranium ore has been mined here and utilized for the manufacture of radium. Pre-war production of radium amounted to about 2 grams per year. When the Germans moved in, they destroyed the whole factory. At this time, the entire stock of radium amounted to 20 grams. The Germans put mining on a high priority and only mining was done throughout the 6 years occupation. The ore was delivered by special planes to Germany and Austria.

Before the Russians entered Czechoslovakia they made arrangements with the Allies to alter their western boundary for the purpose of including the Jachymov mine which they considered of such importance. On arrival, they put a strong guard around the mine. It has been reported that they removed the ore by night in trucks, but this is unconfirmed. Since then the Russians have officially left and the mine is under Czech administration though almost certainly under Russian control. The production at present is 1 gram of radium from 10,000 kgms of ore. Engineer Koblitz has been commissioned to put the radium processing plant into production and has been or will be sent to England or the U.S. to study our method of production. It is not yet certain whether the output will go to the Czechoslovak State for medical purposes or will be exported to Russia.

3. POLDINA-HUT at VITKOVICE (Moravia). [...] The Russians have taken over the whole plant.

4. SIEMENS at CESKE BUDEJOVIC (Bohemia). Two factories were seen from the outside in this town. There was a strong guard outside. Work is going on in altogether 17 Siemens factories and according to a Czech staff officer, it is under Russian supervision because only specially authorized Czechs are allowed there.

5. STALIN WORKS at DUCHCOV (Bohemia). [...] The plant is at present guarded by 400 of the Czech militia.

C. General Report on State of Czech Factories.

All factories formerly engaged on war production and many others besides have been nationalized and are under the control of the so-called National Administrator, who in every case is a Communist and has been installed under Russian influence. In almost all cases, these administrators have proved themselves incapable of running a factory with the result that there has been trouble in the form of protests among the employees. In some cases these administrators have already been removed and replaced by more competent Communists.

[...] None of the Russian Naptha promised in exchange for Czech coal and textile products has been delivered.

D. OBZ [...]

History: OBZ is the secret Service of Czechoslovakia. It was formed... on the instigation of the Red Army. [...]

The whole organization is based on the lines of the NKVD. [...]

The Russians are by no means dependent on the OBZ for secret service activities inside Czechoslovakia. They have their own excellent independent agents who in fact guide the activities of OBZ. [...]

[See document photos on pp. 5520–5527.

Vladimir "Val" Rychly was born in the U.S. in 1909 to parents who were immigrants from Czechoslovakia. He grew up speaking Czech, knew ten other languages, and had a celebrated career in U.S. Naval Intelligence. See: Marvin B. Durning. 2007. *World Turned Upside Down: U.S. Naval Intelligence and the Early Cold War Struggle for Germany.* Washington, D.C.: Potomac Books.

Rychly's report demonstrates how little postwar U.S. inspectors were able to learn of wartime German work in Czechoslovakia. This rare visit, by a lone Navy lieutenant, came after many other U.S. inspectors were denied or sent away empty-handed. Rychly's report does not even mention some of the major known wartime German research and development locations in Czechoslovakia such as Skoda in Pilsen. Of the locations that Rychly does list, most he was not allowed to visit, or everything had been removed from them by the time he visited. Where Rychly was allowed to visit a site that was still active, he was closely escorted by the OBZ Czechoslovakian secret service and denied access to any information they did not want him to have.

Virtually all documentation, prototypes, laboratories, and scientists connected to wartime German work in Czechoslovakia were removed to the Soviet Union. Presumably that information is still buried in Russian archives if it can be found and released.

Is there any relevant surviving information about wartime German work in Czech archives that was not removed or destroyed by the Soviets or their Czech allies?

What other information about wartime German work in Czechoslovakia do the U.S. and U.K. have from intelligence reports or from individuals who escaped to the west? What else can be found in U.S. and U.K. archives?

Rychly's report does not necessarily negate other reports about the Weser/Krizik complex being involved with work related to nuclear weapons and advanced rockets. Since the plant was cleaned out by the time Rychly visited, his only official information about Weser was apparently whatever his OBZ escorts wanted him to hear. As shown in item 8 of Rychly's report (A.E.G. at BEDRICHOV), actual work at these locations was much more extensive than admitted, and details of that work were blocked by the OBZ and other Czech officials.

From several available documents, "Pfau" seems to have been a general name for certain types of automated guidance systems for missiles and torpedoes [see for example pp. 5544, 5554; Trenkle 1987, pp. 121, 123].

Rychly stated that the V-4 rocket was actually "completed," so it was far more than a paper design. The fact that Rychly could mention the V-4 without further explanation suggests that the high-ranking U.S. military officials to whom he was reporting were already well aware of the existence and details of the V-4 rocket. Indeed, according to other U.S. military officials (p. 5544), this V-4 had both an increased range and an improved payload compared to the much better known A-4 (V-2) rocket. For more information on the V-4 rocket in particular and the Rychly reports in general, see pp. 5503ff. and especially 5544.

Volman was a large engineering design and manufacturing company founded and run in Čelákovice by Josef Volman (Austrian/Czech, 1883–1943). Why were the Germans mass-producing cyclotrons at Volman? They reportedly shipped at least three to other German programs during the war, and had at least three left over that were claimed by the Soviet Union after the war. Were cyclotrons being mass-produced at Volman (and elsewhere) and then being used somewhere for electronuclear breeding?

Note that advanced U-boats were being produced, and in the mountains of central Europe. Advanced jet propulsion work was being done there too.

This report is strong evidence that from 1939 to 1945, Germans used uranium ore from Jachymov (and perhaps other sources as well) for a secret, high-priority purpose that was not radium extraction:

- The Germans put uranium ore mining at Jachymov on a high priority no later than 1939 and continued until 1945.
- 10,000 kg of uranium ore yields 1 gram of radium, so if the Germans were primarily interested in the radium, extracting the radium at or near Jachymov would reduce how much material needed to be transported by a factor of 10,000,000, and also avoid contaminating Germany with all the waste byproducts of the extraction. Instead, the Germans destroyed the radium-extraction factory at Jachymov in 1939, never replaced it, and transported away all the ore.
- Uranium ore is very heavy, yet instead of using trains or trucks, the Germans used "special planes" to carry away the ore, again indicating a very high priority as well as a sense of urgency. It is also much harder to trace where planes go than where trains go, so this arrangement conferred a much higher level of security too.
- Officially Germany only had one uranium ore processing facility, Auer near Berlin, but the "special planes" also delivered uranium ore to Austria. What facility or facilities in Austria were processing the uranium ore—Treibacher or other places? Of the ore delivered to Germany, did any go to facilities other than Auer? Did ore only go to Germany and Austria, or could there have been deliveries to processing facilities elsewhere, such as Poland?
- The extreme level of Russian interest in Jachymov may indicate that the Russians knew how the Germans had been using the ore from Jachymov.]

9 August 1945 letter from the Volman company regarding the wartime production of cyclotrons for Germany. [Vojenský historický archiv, Vědecký technický ústav 1945–1946, kart. 1. Courtesy of Jaroslav Mareš.]

Subject: Cyclotron.

We have received your letter of the above dates and thank you especially for the interest you have shown in the cyclotron, substantial parts of which were manufactured in our plant.

The order for the above-mentioned device was awarded to us by the President of the Research Institute of the Reichspost [Amt für Physikalische Sonderfragen], Berlin-Zehlendorf 1 under No. 101 APS 47681 IE-2. The complete device was to be assembled in Miersdorf (über Zeuthen), where a special building was erected for this purpose.

According to the information we have been able to obtain, they already have on site:

1. magnets,
2. a short-wave oscillator supplied by Lorenz Berlin-Tempelhof,
3. vacuum pumping equipment (supplier unknown)
4. ring and dipoles, product of AEG Berlin.

The following parts were supplied by us:

1. High frequency current supply to the pole plates, so called Lecherleitung, with complete water cooling, current supply, shielding device, and adjustable holders,
2. a copper cylinder of 870 mm diameter, 2,000 mm long, fitted with fixing and operating flanges, which are ready to be wound,
3. elbows and a shut-off device to achieve a dilution of 10^{-6} (the relevant pumps were not supplied by us),
4. the previous body between the cylinder and the pole attachments, 1 m long, square on one side, passing into a circular shape with a diameter of 780 mm on the other side, with the appropriate welding flanges (these parts are made of forged copper or brass to achieve a high vacuum),
5. the rail track on the columns to be concreted, the part of the track that comes between the magnets is made of brass (originally they were to be made of remanite).

The other parts, such as the ion source, the slide holder with beryl plate and the current supply for the dipoles, were made by us, but sent to the Radioslavia company, Prague-Vysočany, where they were perhaps destroyed in the air raid of 24 March this year. We assume that Radioslavia could also provide you with some information regarding the device.

[See document photos on pp. 4003–4004.]

Věc : Cyklotron .

Obdrželi jsme Váš dopis shora uvedených dat a děkujeme především za zájem, který jste projevili o cyklotron, jehož podstatné části byly vyráběny v našem závodě.

Zakázka na zmíněné zařízení byla nám zadána presidentem výzkumného ústavu říšské pošty, Berlin - Zehlendorf 1 pod č. 101 APS 47681 IE-2. Kompletní zařízení mělo býti montováno v Miersdorfu / über Zeithen/, kde bylo k tomu účelu postavena zvláštní budova. Podle informací, jež jsme mli možnost získati, nalézají se již na místě :

1./ magnety,

2./ krátkovlný oscilátor, který dodala firma Lorenz Berlin-Tempelhof,

3./ vakuové čerpací zařízení / dodavatel neznám /

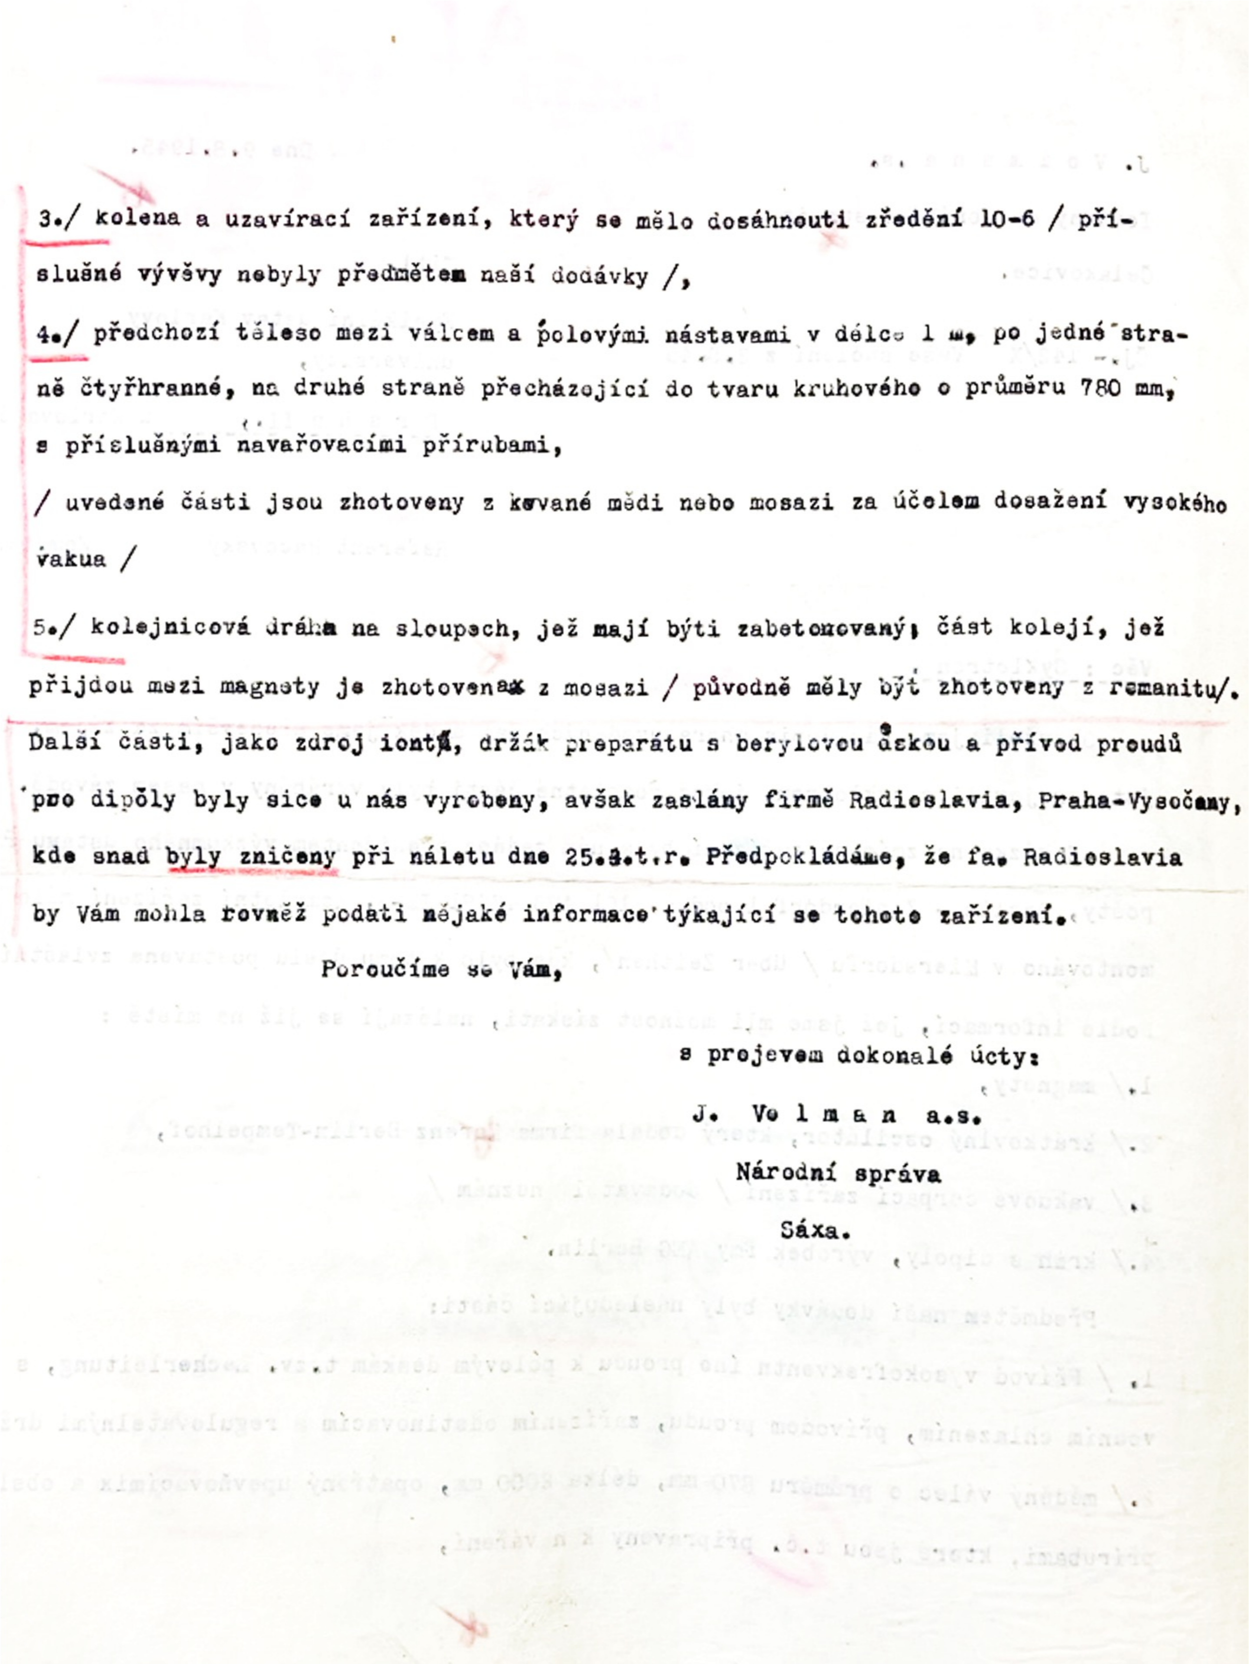
4./ kruh s dipoly, výrobek fmy AEG Berlin.

Předmětem naší dodávky byly následující části:

1. / Přívod vysokofrekventního proudu k pólovým deskám t.zv. Lecherleitung, s úplným vodním chlazením, přívodem proudu, zařízením odstinovacím a regulovatelnými držáky,

2./ měděný válec o průměru 870 mm, délka 2000 mm, opatřený upevňovacími a obsluhovacími přírubami, které jsou t.č. připraveny k navāření,

Figure D.465: 9 August 1945 letter from the Volman company regarding the wartime production of cyclotrons for Germany. [Vojenský historický archiv, Vědecký technický ústav 1945–1946, kart. 1. Courtesy of Jaroslav Mareš.]



3./ kolena a uzavírací zařízení, který se mělo dosáhnouti zředění 10-6 / příslušné vývěvy nebyly předmětem naší dodávky /,

4./ předchozí těleso mezi válcem a polovými nástavami v délce 1 m, po jedné straně čtyřhranné, na druhé straně přecházející do tvaru kruhového o průměru 780 mm, s příslušnými navařovacími přírubami,

/ uvedené části jsou zhotoveny z kované mědi nebo mosazi za účelem dosažení vysokého vakua /

5./ kolejnicová dráha na sloupech, jež mají býti zabetonovány; část kolejí, jež přijdou mezi magnety je zhotovena z mosazi / původně měly být zhotoveny z remanitu/.

Další části, jako zdroj iontů, držák preparátu s beryliovou deskou a přívod proudů pro dipóly byly sice u nás vyrobeny, avšak zaslány firmě Radioslavia, Praha-Vysočany, kde snad byly zničeny při náletu dne 25.3.t.r. Předpokládáme, že fa. Radioslavia by Vám mohla rovněž podati nějaké informace týkající se tohoto zařízení.

Poroučíme se Vám,

s projevem dokonalé úcty:

J. Volman a.s.

Figure D.466: 9 August 1945 letter from the Volman company regarding the wartime production of cyclotrons for Germany. [Vojenský historický archiv, Vědecký technický ústav 1945–1946, kart. 1. Courtesy of Jaroslav Mareš.]

4 October 1945 letter from the Czechoslovakian OBZ security service regarding the wartime production of cyclotrons for Germany. [Vojenský historický archiv, Vědecký technický ústav 1945–1946, kart. 1. Courtesy of Jaroslav Mareš.]

I am submitting the report on the atomic weapon for further discussion by the relevant technical experts:

The OBZ body has sought out the chief designer of the Marconi factory, now Radioslavia, Eng. Klika, at their new factory in Vršovice, tr. Krále Jiřího, former Kanold factory. He tells about the "cyclotron," a device for splitting atoms, which is produced by them:

In the spring of 1944 they received drawings of the components of the atom smashing apparatus from the Reichspost research institute in Berlin. The director of the research institute was Dr. Salow, who also took up the problem. He had about two other assistants with him. They chose a designer, but in the judgment of Mr. Ing. The wrong one, namely from the shipbuilding field, one Tennies. With the help of this engineer they made drawings and commissioned them to various companies. Marconi in Hloubětín received the main part of the "cyclotron", i.e. the "vacuum system" - D electrodes. Part of the vacuum system, i.e. the vacuum space, was handed over to Volman-Celákovice. Stabenov-Křižík still cooperated with Volman in Čelákovice.

The 50 ton magnet was supplied by Kapsch in Vienna. The 50 kW transmitter with 20 m wavelength was made by Lorenz in Berlin. The AEG company in Berlin made the circular crown from brass.

At "Marconi," the commissioner of Marconi, the postmaster Einbeck, Dr. Salow, head of the research institute in Berlin, Tennies, engineer of the same institute and Ing. Klika, chief designer of Marconi. The director Schebesta and the chief designer of the factory, Ruzicka, who was in charge of the whole matter at Volmani, were present from Volmani.

The Marconi company did not achieve any positive results, because they kept encountering construction errors (the designer hard-wired several parts together) and thus deliberately delayed the completion. The raid on Libeň also hit the Marconi factory hard and destroyed everything there, except for some 3 m tubes that belong to the cyclotron. The drawings and blueprints were burned. Volman did have some results and the Germans also took the finished things somewhere just before the change of government. The drawings that were saved by the company were probably handed over by Mr. Ruzicka to the Russian Colonel Petelin, who has been following the whole thing avidly. This officer summoned Ing. Klika and asked for his opinion on the whole apparatus, and wanted him to indicate in red pencil on the drawings, which he would not give him out of hand, the places which would otherwise have to be solved technically, but privately at home. So far this has not happened, because Ing. Klika has reproached him for the whole apparatus being structurally all wrong.

Ing. Klika is surprised that foreign countries have already become interested in the "cyclotron," whereas our army has not shown interest in it so far. He claims that directly at the Marconi company he has a very good calculator who, using basic measurements and with the cooperation of several experts from different branches, could constructively solve and manufacture the device, after getting pre-war literature from America (which was previously freely printed). The literature needs to be used as a basis so that one does not have to work from scratch.

Mr. Ing. Klika characterises Ing. Růžička as a man who had read something in a hurry, because in conversation he “name-drops” ions and other words. He is a 50-year-old gentleman who wants to improve his position and therefore tried to get as many details as possible from Colonel Petyelin. The colonel belongs to a trophy troop still in Prague. He lives somewhere on Rokoska /:on Hanspaulka:/.

Ing. Klika has the impression that German military circles have issued an appeal to all research institutes in the Reich to look into this problem. He points out that the Rhode & S[ch]warz, Munich, produced the “cyclotron” or its components for the Manfred von Ardenne Institute in Berlin [Forschungslaboratorium für Elektronenphysik]. This “cyclotron” was probably finished. The problem was not a new one, because already in 1936 a “cyclotron” had been produced by Brown-Boveri for the Zurich Technique.

At an unofficial meeting of industrialists, attended by Dr. Matula, head of the Radiological Institute, Director Ostrčil, Havelka, Colonel Mrázek, Dr. Hrdina, Ing. Klika, Colonel Vaněk from the Western Army, proposed a kind of research institute where the problem would be continued. Colonel Vanek, who himself had chased V1 weapons on a fighter, discussed these weapons and the V2, against which there was no defence at all because of its amazing speed of 5,000 km per hour at 100 km. He points out that the V2 with its atomic charge is the weapon of the future. The V2 was fired perpendicularly upwards, guided between 4 radio beams, at 100km altitude it encountered a horizontal beam on which it straightened out, and at that altitude it continued horizontally guided by that beam to above the target, where it crashed to earth in a parabola. V2 was produced in Jirkov near Ervenice.

Ministerstvo národní obrany,
Hlavní správa O B Z .,
P r a h a .

Na základě zákona číslo 412/2003 Sb., § 22 byl stupeň utajení zrušen.
Datum: 25 -01- 2010
Podpis:

Předkládám zprávu o atomové zbrani k dalšímu jednání příslušnými technickými odborníky :

Orgán OBZ vyhledal šefkonstruktera továrny Markoni nyní Radioslavia ing. Kliku, v jejich nové továrně ve Vršovicích, tř. Krále Jiřího, bývalá továrna Kanold. O "Cyklotronu", přístroji na rozbíjení atomů, který se u nich vyráběl vypovídá :

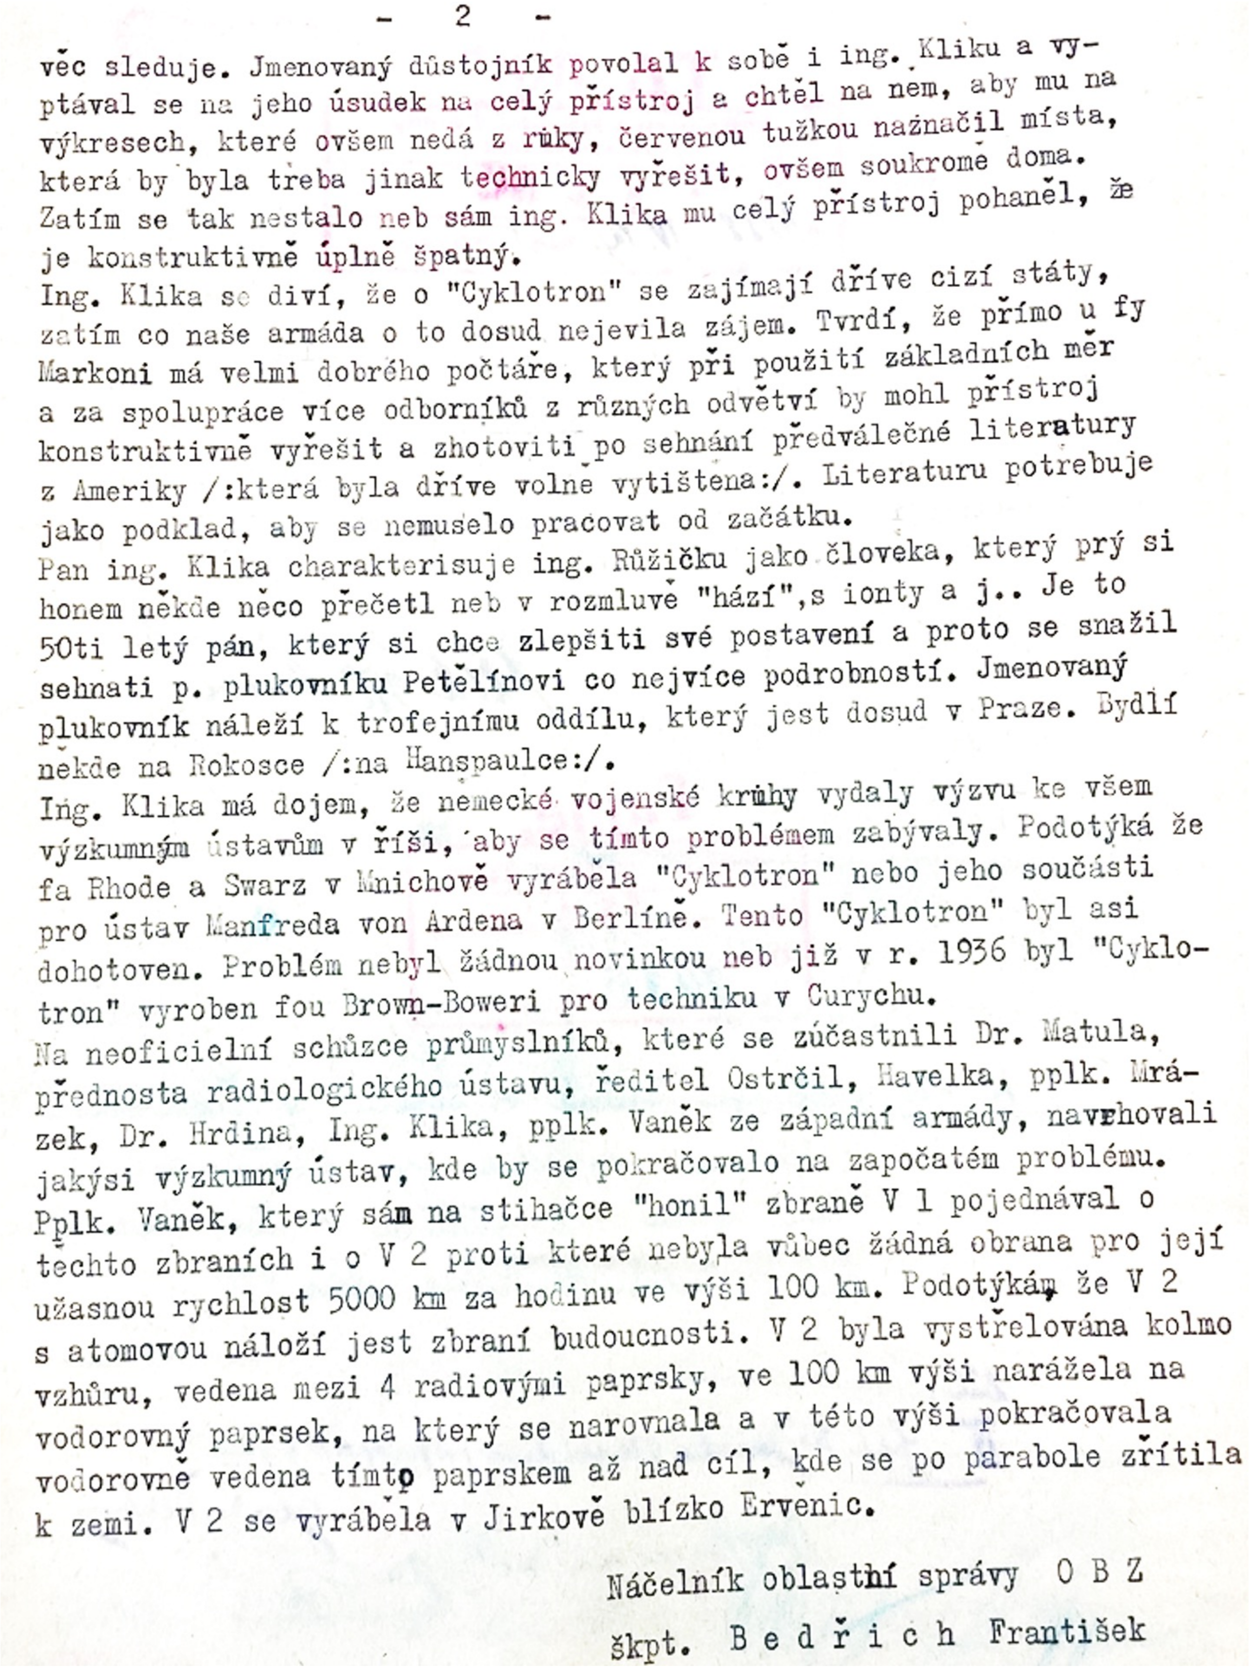
Na jaře roku 1944 obdrželi od výzkumného ústavu říšských pošt v Berlíně výkresy součástek aparátu na rozbíjení atomů. Ředitelem výzkumného ústavu byl Dr. Salow, který se také tohoto problému ujal. Měl při sobě ještě asi dva pomahače. Vybrali si konstruktera, ovšem dle úsudku p. Ing. Kliky chybného, totiž z oboru loďařského, jakéhosi Tenniese. Pomocí tohoto konstruktéra zhotovili výkresy a zadali je různým firmám. Markoni v Hloubětíně obdržel hlavní část "Cyklotronu" t.j. "Vakuový system"-D elektrody. Část Vakuového systemu t.j. Vakuový prostor byla předána fě Volman - Čelákovice. S Volmanem ještě spolupracoval v Čelákovicích Stabenov-Křižík.

Magnet 50 tun těžký dostala fa Kapsch ve Vídni. Vysílač 60 kw s 20 m delkou vlny fa Lorenz v Berlíně. Fa AEG v Berlíně dělala kruhovou korunu z mosazi.

U "Markoni" se zúčastňovali porad komisař fy Markoni poštovní rada Einbeck, Dr. Salow přednosta výzkumného ústavu v Berlíně, Tenies konstruktér téhož ústavu a ing. Klika šefkonstruktér fy Markoni. Od Volmanů se zúčastňoval ředitel Schebesta a šefkonstruktér tov. Růžička, který měl celou věc u Volmanů na starosti.

U fy Markoni k žádnému kladnému výsledku nedošli, neb stále naráželi na konstruktívní chyby, /:konstruktér na tvrdo spájel několik částí dohromady:/ a tím schválně dohotovení zdržovali. Nálet na Libeň postihl těžce též továrnu Markoni a vše tam zničil až na jakési 3 m trubice, které k cyklotronu patří. Výkresy a nákresy shořely. U Volmanů opravdu nějaké výsledky měli a hotové věci také němci těsně před revolucí někam odvezli. Výkresy, které podnik zachránil předal pravdepodobně pan Růžička ruskému plukovníku Petělínu, který horlivě celou

Figure D.467: 4 October 1945 letter from the Czechoslovakian OBZ security service regarding the wartime production of cyclotrons for Germany. [Vojenský historický archiv, Vědecký technický ústav 1945–1946, kart. 1. Courtesy of Jaroslav Mareš.]



- 2 -

věc sleduje. Jmenovaný důstojník povolal k sobě i ing. Kliku a vyptával se na jeho úsudek na celý přístroj a chtěl na něm, aby mu na výkresech, které ovšem nedá z ruky, červenou tužkou nažnačil místa, která by byla třeba jinak technicky vyřešit, ovšem soukromě doma. Zatím se tak nestalo neb sám ing. Klika mu celý přístroj pohaněl, že je konstruktivně úplně špatný.

Ing. Klika se diví, že o "Cyklotron" se zajímají dříve cizí státy, zatím co naše armáda o to dosud nejevila zájem. Tvrdí, že přímo u fy Markoni má velmi dobrého počtáře, který při použití základních měr a za spolupráce více odborníků z různých odvětví by mohl přístroj konstruktivně vyřešit a zhotoviti po sehnání předválečné literatury z Ameriky /:která byla dříve volně vytištena:/. Literaturu potrebuje jako podklad, aby se nemuselo pracovat od začátku.

Pan ing. Klika charakterisuje ing. Růžičku jako člověka, který prý si honem někde něco přečetl neb v rozmluvě "hází",s ionty a j.. Je to 50ti letý pán, který si chce zlepšiti své postavení a proto se snažil sehnati p. plukovníku Petělínovi co nejvíce podrobností. Jmenovaný plukovník náleží k trofejnímu oddílu, který jest dosud v Praze. Bydlí někde na Rokosce /:na Hanspaulce:/.

Ing. Klika má dojem, že německé vojenské kruhy vydaly výzvu ke všem výzkumným ústavům v říši, aby se tímto problémem zabývaly. Podotýká že fa Rhode a Swarz v Mnichově vyráběla "Cyklotron" nebo jeho součásti pro ústav Manfreda von Ardena v Berlíně. Tento "Cyklotron" byl asi dohotoven. Problém nebyl žádnou novinkou neb již v r. 1936 byl "Cyklotron" vyroben fou Brown-Boweri pro techniku v Curychu.

Na neoficielní schůzce průmyslníků, které se zúčastnili Dr. Matula, přednosta radiologického ústavu, ředitel Ostrčil, Havelka, pplk. Mrázek, Dr. Hrdina, Ing. Klika, pplk. Vaněk ze západní armády, navrhovali jakýsi výzkumný ústav, kde by se pokračovalo na započatém problému. Pplk. Vaněk, který sám na stihačce "honil" zbraně V 1 pojednával o těchto zbraních i o V 2 proti které nebyla vůbec žádná obrana pro její užasnou rychlost 5000 km za hodinu ve výši 100 km. Podotýkám že V 2 s atomovou náloží jest zbraní budoucnosti. V 2 byla vystřelována kolmo vzhůru, vedena mezi 4 radiovými paprsky, ve 100 km výši narážela na vodorovný paprsek, na který se narovnala a v této výši pokračovala vodorovně vedena tímto paprskem až nad cíl, kde se po parabole zřítila k zemi. V 2 se vyráběla v Jirkově blízko Ervenic.

Report on the Interrogation of Miraslow JIRKU.

(To be read in conjunction with CIC report of 11 April 1946)

(Attached as Appendix I).

Interrogated by:-	Lt. W.L. Warner.	U.S. Embassy.
	Dr. G.O. Baines.	Ministry of Supply.
	R.D. Clausen,	C.I.C. (Kassel) was also present.

Subject was interrogated on 17th April 1946 at Kassel (L52/C20).
This interrogation was confined mainly to technical matters.

He stated that he had been engaged at a research station at Johannisthal in the Sudetenland. By questioning him as to details of the place, the numbers of mine shafts etc, it was inferred that the place was Joachimsthal (N51/K60), although it should be mentioned that there are six Johannesthals listed in the Gazetteer. The subject stated on interrogation that Johannesthal was the German name for Joachimsthal.

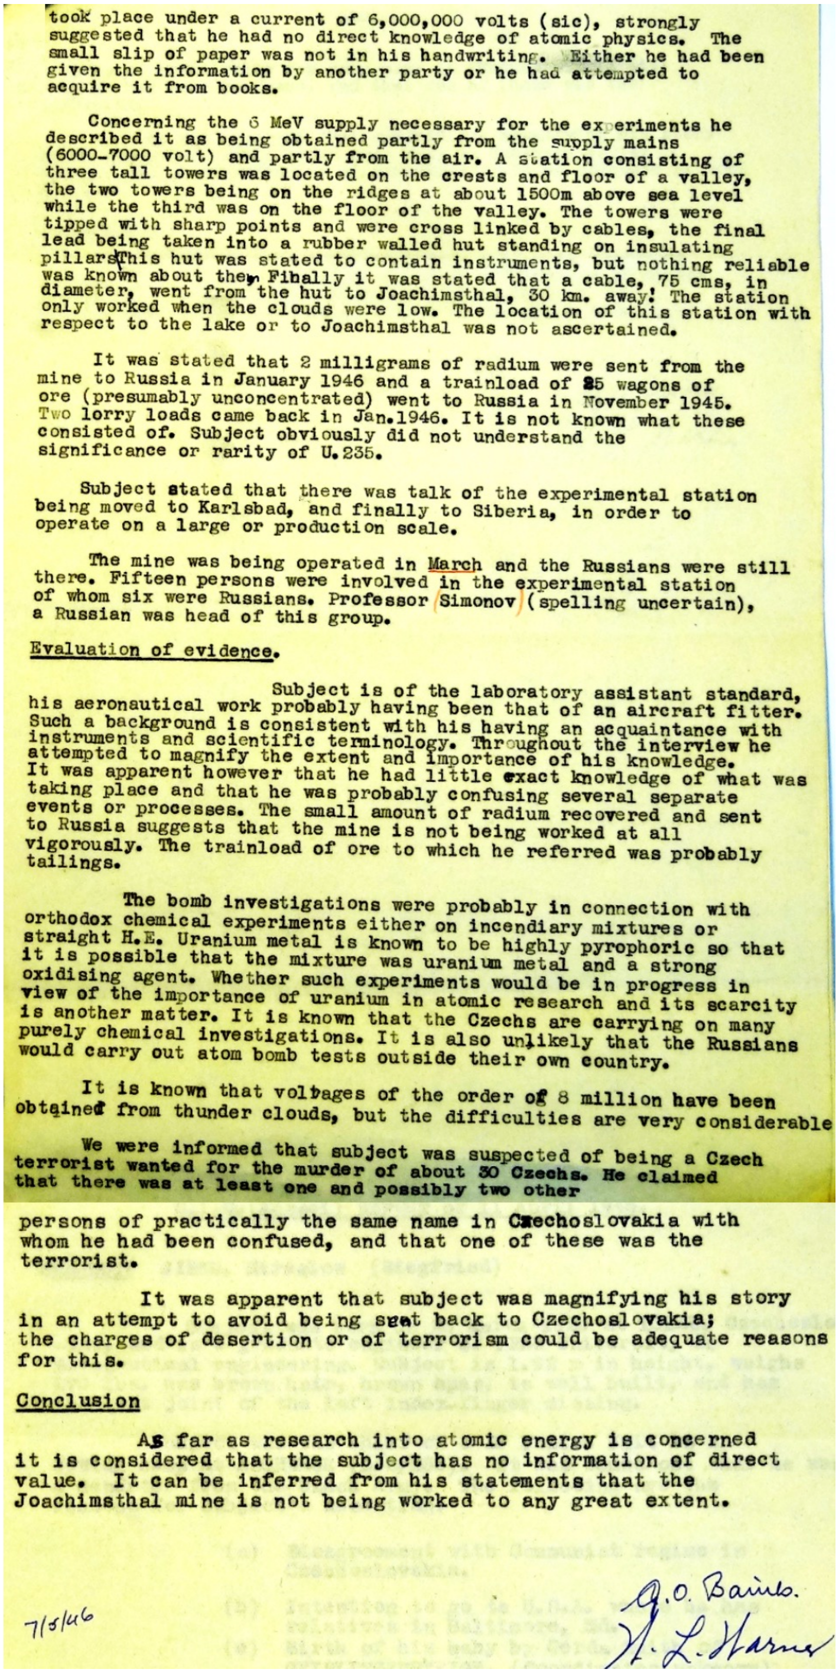
Subject was at this station from Nov. 1945 to March 1946. Initially he was an espionage agent in the plant but later, owing to his technical training, he was given work on the technical side. This work appears to have consisted principally of recording data at the explosion of bombs dropped into the centre of a lake. This lake cannot be located on any map, but from a description of its position and shape, it is considered that it maybe the small lake at N51/K4615 which is some 16 miles from Joachimsthal. Four sets of instruments were located on the perimeter of the lake, leads from which were taken to one recording point in a bunker about 20m from the lake. Subject was in this bunker and stated that the temperature of the lake was recorded. It went up from 18°C to 80°C on the average. This is so improbable that it is suggested that subject was merely recording a change of electrical current or potential, and that he did not know what property was being measured. The bombs which were of two calibres, 12-15cm. and 45-50cms were of such shape that they would detonate on first striking the water. It was stated that less than $\frac{1}{2}$ kg. of material was used and that $\frac{1}{2}$ kg. would give an explosion equal to that of the bomb used at Hiroshima. With the smaller bomb the explosion was ten times greater than that obtained with nitroglycerine (sic). The bombs were filled with a mixture of the old and new materials. This point should be noted since later he stated that the new method, which had been obtained from America by espionage, has not yet been tried. Many bombs did not explode. The bombs came to Joachimsthal unfilled and were then filled with the uranium mixture.

A small piece of paper was produced which was supposed to give the methods of fission. On one side were written the various ways in which U235 can break up into, barium and krypton etc, while the other gave the neutron and proton constitutions of the oxygen atom and of U235. This was supposed to have some connection with the new method of fission. When asked to copy out this paper, which was written in indelible pencil and had become somewhat smudged, subject was unable to do so correctly, particularly as regards the smudged names. This and the general way, in which subject described both the old and the new methods, in which fission

NARA RG 77, Entry UD-22A, Box 168, Folder 68.91. US: Russian Int in US

Figure D.470: W. L. Warner, G. O. Baines, Robert D. Clausen, and Henry D. Treitel. 7 May 1946. Report on the Interrogation of Miraslow JIRKU [NARA RG 77, Entry UD-22A, Box 168, Folder 68.91. US: Russian Int in US].

DECLASSIFIED
Authority NND 917017



took place under a current of 6,000,000 volts (sic), strongly suggested that he had no direct knowledge of atomic physics. The small slip of paper was not in his handwriting. Either he had been given the information by another party or he had attempted to acquire it from books.

Concerning the 6 MeV supply necessary for the experiments he described it as being obtained partly from the supply mains (6000-7000 volt) and partly from the air. A station consisting of three tall towers was located on the crests and floor of a valley, the two towers being on the ridges at about 1500m above sea level while the third was on the floor of the valley. The towers were tipped with sharp points and were cross linked by cables, the final lead being taken into a rubber walled hut standing on insulating pillars. This hut was stated to contain instruments, but nothing reliable was known about them. Finally it was stated that a cable, 75 cms, in diameter, went from the hut to Joachimsthal, 30 km. away! The station only worked when the clouds were low. The location of this station with respect to the lake or to Joachimsthal was not ascertained.

It was stated that 2 milligrams of radium were sent from the mine to Russia in January 1946 and a trainload of 25 wagons of ore (presumably unconcentrated) went to Russia in November 1945. Two lorry loads came back in Jan.1946. It is not known what these consisted of. Subject obviously did not understand the significance or rarity of U.235.

Subject stated that there was talk of the experimental station being moved to Karlsbad, and finally to Siberia, in order to operate on a large or production scale.

The mine was being operated in March and the Russians were still there. Fifteen persons were involved in the experimental station of whom six were Russians. Professor Simonov (spelling uncertain), a Russian was head of this group.

Evaluation of evidence.

Subject is of the laboratory assistant standard, his aeronautical work probably having been that of an aircraft fitter. Such a background is consistent with his having an acquaintance with instruments and scientific terminology. Throughout the interview he attempted to magnify the extent and importance of his knowledge. It was apparent however that he had little exact knowledge of what was taking place and that he was probably confusing several separate events or processes. The small amount of radium recovered and sent to Russia suggests that the mine is not being worked at all vigorously. The trainload of ore to which he referred was probably tailings.

The bomb investigations were probably in connection with orthodox chemical experiments either on incendiary mixtures or straight H.E. Uranium metal is known to be highly pyrophoric so that it is possible that the mixture was uranium metal and a strong oxidising agent. Whether such experiments would be in progress in view of the importance of uranium in atomic research and its scarcity is another matter. It is known that the Czechs are carrying on many purely chemical investigations. It is also unlikely that the Russians would carry out atom bomb tests outside their own country.

It is known that voltages of the order of 8 million have been obtained from thunder clouds, but the difficulties are very considerable

We were informed that subject was suspected of being a Czech terrorist wanted for the murder of about 30 Czechs. He claimed that there was at least one and possibly two other persons of practically the same name in Czechoslovakia with whom he had been confused, and that one of these was the terrorist.

It was apparent that subject was magnifying his story in an attempt to avoid being sent back to Czechoslovakia; the charges of desertion or of terrorism could be adequate reasons for this.

Conclusion

As far as research into atomic energy is concerned it is considered that the subject has no information of direct value. It can be inferred from his statements that the Joachimsthal mine is not being worked to any great extent.

7/5/46

TOP SECRET

Appendix I.

C.I.C.(Kassel) REPORT of 11 April 1946.

SUBJECT: JIRKU, Miraslow (Siegfried)

Subject was born on 28 March 1920 at IGLAU, Czechoslovakia, and is a graduate engineer of PRAG University in aeronautical engineering. Subject is 1.92 m in height, weighs 170 lbs, has brown hair, brown eyes, is well built, and has the last joint of the left index-finger missing.

Subject was the chief of a DP Police Unit in a Jewish camp at ESCHWEGE (L52/H68). It was found out that he was a deserter from the Czech Army. The following are the reasons for Subject's desertion:

(a) Disagreement with Communist regime in Czechoslovakia.
(b) Intention to go to U.S.A. where he has relatives in Baltimore, Md.
(c) Birth of his baby by Gerda Smith of GEISLINGENSTEIGE. (Coordinates unknown) near STUTTGART.

Upon learning that Subject is a deserter from the Czech army, UNRRA director Miss GRANT, notified the Czech liaison at KASSEL (L52/C20). As a result, Subject was arrested by the German police probably at the request of the Czech Liaison, and turned in to the prison of ESCHWEGE on 21 March 1946. On or about 1 April 1946 he was interviewed by a Czech liaison officer (name unknown) and was informed that he would be returned to Czechoslovakia.

Subject then requested an interview with the nearest American Intelligence Officer. He was directed to Second Lieutenant MUSH, S-2, 3rd Bn., 30th Inf. Regt. He stated that he had interesting information about the progress of atomic research.

On 10th April 1946 Subject was interrogated by Special Agent Treitel, CIC. It was learned that Subject had been in a concentration camp prisoner for about two and one half years, and was liberated in the vicinity of NURNBERG on 6 April 1945 by American troops. He was an inmate of the MATTHAUSEN concentration camp. Subject was repatriated into Czechoslovakia in May, 1945 and immediately joined the Czech army, attended Officer's training school at KARLSBAD (Coordinates unknown) until November 1945, and then was stationed at an "Atomic Energy Research Station" in the SUDETENLAND at JOHANNISTALL (Coordinates unknown), in the Russian occupation zone in Czechoslovakia.

Primarily employed to do espionage work under OBZ (Czechoslovakian equivalent of CIC) in the plant, he was discovered to have the necessary technical knowledge to work actively in the laboratory, and was thus employed. Thereupon he relinquished all espionage work. Officially under Czechoslovakian management, the work in this plant was being accomplished for the Russians. When Czechoslovakia was no longer partitioned into occupational zones, several Russians remained in JOHANNISTALL and continued to work on the same project as Subject. Subject claims that in February 1946 high ranking Russian officers, four civilians, and a Czech officer (See appendix C) held a party to celebrate the success of espionage work in the U.S.A. regarding atomic energy. i.e. the third instance of detonation. (~~See Appendix A~~). This secret was

TOP SECRET

-2-

obtained from an inebriated Russian Captain by Subject on the night of the celebration. Subject produced this formula from under a fairly large sized ring he was wearing, after lengthy interrogation.

C.I.C. not being technically in the position to do so, cannot adequately evaluate the scientific merit of the information preferred by the Subject.

The name of the inebriated Russian Captain is SIMONOW, fnu. His description: Russian, 175 to 180 m in height, heavy, small pig-like eyes, bald, no moustache, wears glasses (dark-rimmed) constantly smokes a cigar, and is approximately 56 years of age. He is always in the company of a police dog named ROLF, formerly property of Subject (~~See Encl.B.~~)

This Russian Captain, from whom Subject obtained the information, supposedly got news of the scoop of the espionage-service in America directly from Russia, where it had been sent to ' from a State in the U.S.A. near the Mexican border' through FRANKFURT. The information from the U.S.A. had been sent by a German in the U.S.A. in the 'State near the Mexican border', engaged in the same work as Subject was i.e. prooving ground for atomic energy. This German's description: Typically Nordic - tall, strong, apparently blond, manly, protuding chin - and allegedly engaged. His photograph is in the possession of Subject's friend, (Karl NOWOTNY,) in JOHANNISTALL.

Subject assumes that letters from the 'State near the Mexican border' in the U.S.A. reached a certain DORIS FRITSCHE, Hermannstrasse 5 , ESCHWEGE, V-1 technician and UNRRA employee at the DP camp No.522 in ESCHWEGE, by way of FRANKFURT, where they had been placed into new envelopes ~~in~~ bearing the post-mark FRANKFURT. Subject has seen letters in DORIS FRITSCHE's hands, headed 'New Mexico'.

Description of DORIS FRITSCHE: 1.90 m. in height, wears glasses, brown hair, blue eyes, approximately 32 years of age, twice divorced, one child of seven and, according to Subject, a devout Nazi.

DORIS FRITSCHE has in her possession, according to Subject, a photograph of a man sending her communications from the U.S.A. This picture, however, does not resemble the one shown Subject by the Russian Captain as being the source of the Captain's information from the U.S.A. and it can be assumed that either one or both of the photographs are fictitious.

The validity of Subject's statements cannot be ascertained at this stage. Subject asserts that Russians have definitely decided that there is no compromise between Communism and Capitalism and that a war between Russia and the Western Allies is unavoidable.

Personalities mentioned in ESCHWEGE - DORIS and GERTY FRITSCHE will be apprehended by CIC for further interrogation and to substantiate the story of the Subject.

Henry D.Treitel.
Special Agent, CIC.

Robert D.Clausen

Figure D.473: W. L. Warner, G. O. Baines, Robert D. Clausen, and Henry D. Treitel. 7 May 1946. Report on the Interrogation of Miraslow JIRKU. Appendix I [NARA RG 77, Entry UD-22A, Box 168, Folder 68.91. US: Russian Int in US].

Vladimir L. Rychly. Cyclotrons Manufactured in Czechoslovakia. 2 September 1946. [NARA RG 38, Entry 98C, Box 11, Folder TSC # 3101–3200]

1. Attempts to manufacture cyclotrons for Laboratory nuclear physics research were made in Čelakovice, Czechoslovakia (15 miles East of Praha) by three major Čelakovice Industrial plants:

a.) Volman, Čelakovice,

b.) Radioslavia, Čelakovice,

c.) Křižík, Čelakovice.

All original plans for the Cyclotron construction originated in Germany. The work in Čelakovice was under German supervision, and the construction was the responsibility of the following German engineers:

a.) dr. Bajer,

b.) dr. Salow,

c.) dr. Ing Tönies.

The cyclotron completed in Čelakovice was originally intended for the German nuclear physics research laboratory in MIERSDORF in Germany. It was composed out of 6 main sections, namely:

a.) electro-magnet,

b.) vacuum pumps,

c.) tubes,

d.) crown-chamber with D-poles,

e.) cylinder,

f.) railes.

Čelakovice was responsible for the last three sections of the Cyclotron. The first three sections were the commitment of other factories either in Germany or in Czechoslovakia. There is some scant evidence to believe that the Siemens plant in Praha was charged with the responsibility of completing the required tubes for the cyclotron. The electro-magnet, according to engineers responsible to the German authorities was a huge affair of several hundred tons. This was a mere guess, as the electro-magnet, when seen completely crated, loaded on two large flat-cars and ready for shipment.

2. The attached sketch of the Cyclotron section d. e. and f. [p. 4019] obtained from dr. Ing. Ružek, Chief Constructor of the Volman plant in Čelakovice, may provide possibilities for detailed information. As all original drawings and documents were confiscated by the Soviet missions during the days of occupation, the only possible indication of the capacity of the completed cyclotron in Čelakovice, is the intensity of the radiation (illumination) in that section of the cyclotron in which the protons hasten the nucleus of the hydrogen atom as the circulating electrons are freely released. The intensity of the radiation (illumination) is claimed to be $6 \cdot 10^6$ volts.

3. The main difficulties encountered during the work on the first attempts to complete a cyclotron in Čelakovice were defeated as the work progressed. [...]

4. As soon as the Russian troops occupied Czechoslovakia, the three plants in Čelakovice were completely surrounded by Russian guards, and members of the Soviet Technical Units made necessary arrangement to have the cyclotron pre-tested, and all defective materials removed. As more commissions arrived from Russia the popularity of the Čelakovice Cyclotron increased. However, it was not until November 1945 that the Cyclotron was carefully crated and removed to Russia. Destination unknown. [...] However, not one single part of Cyclotron construction remained in Czechoslovakia.

[See document photos on pp. 4016–4019.]

Vladimir L. Rychly. 31 October 1946. Cable IN 175. [NARA RG 77, Entry UD-22A, Box 160, Folder 205.2 Cables Incoming, Top Secret]

Volmann never engaged nuclear physics research. Refer CNO 122106. He was proprietor of famous Czecho factory in Čelakovice near Praha and directly responsible for cyclotron delivery to German Reichspost nuclear physics laboratory in Miersdorf, Germany. Factories Radioslavia and Krizik both located Čelakovice only assisted in construction. German specialists Dr Baier, Dr Salow, Ing Tonies supervised cyclo construction all three plants. Rheotron designations used by Soviets during inspection Volmann plant.

New Subject:
All pitchblende ore from Jacymov leaving Czecho for Soviet Zone Germany. Present status activity Jacymov mines under investigation.

[These further reports by Rychly give a great deal of additional information about the cyclotron(s) produced in wartime Czechoslovakia.

Based on the reported 6 MeV energy and the physical size of the cyclotron, it sounds very similar to the cyclotrons at the University of California Berkeley that Ernest Lawrence used to produce microgram quantities of plutonium in 1940. Was the German program in 1945 at roughly the same point as Lawrence's experiments in 1940? Or as an alternative to using a fission reactor to produce plutonium, were the Germans trying to produce physically useful quantities of plutonium-239 (or possibly uranium-233) by operating a number of cyclotrons in parallel for a long period of time (electronuclear breeding)?

On the other hand, perhaps the cyclotrons, or modified versions of cyclotrons, were intended to serve as electromagnetic separators to enrich uranium-235 from natural uranium.

One of the Reichspost's nuclear research facilities was located in Miersdorf. Scholars should investigate much further to find out exactly what work was conducted at that and other Reichspost facilities.]

plant in Praha was charged with the responsibility of completing the required tubes for the cyclotron. The electro-magnet,according to engineers responsible to the German authorities was a huge affair of several hundreds tons.This was a mere guess,as the electro-magnet,when seen was completely crated,loaded on two large flat-cars and ready for shipment.

2. The attached sketch of Cyclotron sections d. e. and f. obtained from dr.Ing.Růžek,Chief Constructor of the Vollman plant in Čelakovice,may provide possibilities for detailed information. As all original drawings and documents were confiscated by the Soviet missions during the days of occupation,the only possible indication of the capacity of the ~~only~~ completed cyclotron in Čelakovice, is the intensity of radiation(illumination) in that section of the cyclotron in which the protons hasten the nucleus of the hydrogen atom as the circulating electrons are freely released. The intensity of the radiation (illumination) is claimed to be 6.10^6 evolts.

3. The main difficulties encountered during the work on the first attempts to complete a cyclotron in Čelakovice were defeated as the work progressed. The selection of proper welding material was the main setback.Most materials failed during the vacuum and pressure tests,and finally silver was used to weld:

a.) The 3 meter conduction of electric power with built in cooling system of double brass tubes(about 100 ø)

b.) the armature,

c.) the intake of ionized hydrogen into the crown-chamber between the poles of the magnet,

d.) the intake of VF power,

e.) the tubes for the necessary preparations,

f.) the filters with plate attachments for beryllium,and pole extensions with a cooling device made of copper.

The cover for the cylinder,originally intended to be manufactured out of regular commercial copper did not possess the proper density. Thus remanit, and

Figure D.477: Diagram of a cyclotron manufactured in German-occupied Czechslovakia for the German nuclear program. Vladimir L. Rychly. Cyclotrons Manufactured in Czechoslovakia. 2 September 1946 [NARA RG 38, Entry 98C, Box 11, Folder TSC # 3101–3200].

Vladimir L. Rychly. 17 December 1946. Russia—Soviet Nuclear Research Apparatus. [NARA RG 38, Entry 98C, Box 12, Folder TSC # 3401–3500]

During one of his lectures conducted at the Charles University in Praha, Czechoslovakia, Dr. Ing. Kolmann who spent over 15 years in Russia, in a brief discussion on Atomic Research in U.S.S.R., claimed:

(1) The Soviets have in their possession one of the largest cyclotrons that was ever built. It was originally designed for the Soviet Academy of Science.

DESCRIPTIONS:

(a) The weight of the electro-magnet approximately 1000 tons.

(b) The size of poles were estimated as follows:

(1) diameter————— 3 meters
(2) height————— 8 meters
(3) length————— 8 meters

Serious difficulties were encountered as the cyclotron was installed. The building in which the cyclotron at present is located was heavily insulated. The estimated size of the building is about 12,000 cubic metres.

It was stated that this cyclotron is capable of producing deut[er]ons with an energy of approximately 50 million electron-volts.

(2) The Soviet Academy of Science is about ready to install the newly developed synchrotron for experimental purposes. It is expected that the energy of the synchrotron will be about 300 million electron-volts.

(3) In his technical publication Dr. Ing. Kolmann made some mention of the betatron which has several advantages over the cyclotron. The betatron is said to be much smaller than the cyclotron. Based upon the principal of an electronic lamp with a diameter of about 300 millimeters, the electric current produced by the electronic lamp receives quicker action from the installed magnetic fields. The energy produced by this so-called "electronic speedster" was estimated at about 100 million electronic volts.

[It seems quite unlikely that such very large particle accelerators were produced by the Soviet Union itself during or immediately after the war, when the Soviet Union was desperately fighting or recovering from the war, very deficient in both scientists and scientific equipment, and devoting all available resources to more fundamental priorities.

Rather, it seems much more likely that these very large particle accelerators were produced by and for wartime German programs. The report mentioned that "serious difficulties were encountered as the cyclotron was installed." That suggests that the cyclotron was not designed and built for the space where it was ultimately installed, and that it was not installed by the people who designed and built it.

Similarly, the 300 MeV synchrotron and the 100 MeV betatron mentioned in the same report were probably also produced by wartime German programs.]

Subject RUSSIA - Soviet Nuclear Research Apparatus.
(Nation reported on) (Main title as per index guide) (Subtitles) (Make separate report for each title)

BRIEF. (Here enter careful summary of report, containing substance succinctly stated; include important facts, names, places, dates, etc.)

During one of his lectures conducted at the Charles University in Praha, Czechoslovakia, Dr. Ing. Kolmann who spent over 15 years in Russia, in a brief discussion on Atomic Research in U.S.S.R., claimed:

(1) The Soviets have in their possession one of the largest cyclotrons that was ever built. It was originally designed for the Soviet Academy of Science.

DESCRIPTIONS:

(a) The weight of the electro-magnet approximately 1000 tons.
(b) The size of poles were estimated as follows:
  (1) diameter - - - - - - - - - - - - - - - - - 3 meters
  (2) height - - - - - - - - - - - - - - - - - - 6 meters
  (3) length - - - - - - - - - - - - - - - - - - 8 meters

FN has seen
F12 has seen
Op36

Serious difficulties were encountered as the cyclotron was installed. The building in which the cyclotron at present is located was heavily insulated. The estimated size of the building is about 12,000 cubic metres.

It was stated that this cyclotron is capable of producing deutons with an energy of approximately 50 million electron-volts.

(2) The Soviet Academy of Science is about ready to instal the newly developed synchronotron for experimental purposes. It is expected that the energy of the synchronotron will be about 300 million electron-volts.

(3) In his technical publication Dr. Ing. Kolmann made some mention of the betatron which has several advantages over the cyclotron. The betatron is said to be much smaller than the cyclotron. Based upon the principal of an electronic lamp with a diameter of about 300 millimetres, the electric

Figure D.478: Vladimir L. Rychly. 17 December 1946. Russia—Soviet Nuclear Research Apparatus [NARA RG 38, Entry 98C, Box 12, Folder TSC # 3401–3500].

Col. Baskin R. Lawrence. 4 June 1947. Memorandum for Chief, Air Intelligence Division. Subject: Daily Activity Report. [AFHRA folder 122.25 Mar–July 1947; AFHRA A1036 frames 2238–2239]

[...] The Intelligence Review of 1 May 1947 contains an item which may go far to explain the Sukhumi problem. It will be recalled that there were reports to the effect that the Russians were building in the Sukhumi area an atomic bomb plant in dimensions as large as Oak Ridge. It will also be recalled that there were various reasons why these reports seemed to be unreliable.

However, the reports contained the specific information that German physicists had been seen traveling through Sukhumi. The Intelligence Review (p. 62) now reveals that a small cyclotron, which the Russians had removed from Berlin, was installed at Sukhumi. Since cyclotrons, especially of a small size, are laboratory equipment, and are not needed in the actual production of atomic bombs or atomic materials, the conclusion may be drawn that the Russians established at Sukhumi a nuclear physics laboratory.

Attention is invited to the fact that two larger cyclotrons, classed as "moderate" in size were removed by the Russians from Leipzig and Czechoslovakia. Their present location is unknown.

[All of the documents in this section raise the same question. Why was Germany building so many particle accelerators, and accelerators with such high energies, as a very high priority during and even late in the war? That could not have been justified by pure science experiments. There must have been a clear wartime purpose, such as electronuclear breeding of Pu-239 and/or U-233.]

IN REPLY REFER TO:

4 June 1947

MEMORANDUM FOR CHIEF, AIR INTELLIGENCE DIVISION

SUBJECT: Daily Activity Report

1. Dr. Kossack and Mr. Grassy are preparing an outline of proposed AAF specific requirements in terminal ballistic research. Lt. Col. Maupin, Requirements Division, AC/AS-3, at a recent conference, requested the Physical Vulnerability Section to draft the outline. (Confidential)

Items of Interest:

A member of Headquarters Third Army, Miami, Florida, recently obtained the following information in an interview with Juan Conrads, owner of the Conrads Steel Wire Milling Company at Santiago, Chile. Sr. Conrads stated that the future of the steel business in Chile is very bright. Heretofore, all raw manufactured steel has had to be imported from the United States, Chile itself having no resources to provide the raw steel from within the country. Now, however, the Chilean Government is building a very large raw steel mill in the southern part of the country near the soft coal deposits. Eventually, this means that Chile will be entirely self-sufficient for its raw steel and will not have to import it from the outside.

Sr. Conrads stated he expects the profits from his own company will be almost doubled and this should happen within the next year. This is significant in that it means that the United States' export of raw steel to Chile will be done away with almost entirely, and Chile will be self-sufficient in this regard. (Confidential)

The Intelligence Review of 1 May 1947, contains an item which may go far to explain the Sukhumi problem. It will be recalled that there were reports to the effect that the Russians were building in the Sukhumi area an atomic bomb plant in dimensions as large as Oak Ridge. It will also be recalled that there were various reasons why these reports seemed to be unreliable.

However, the reports contained the specific information that German physicists had been seen traveling through Sukhumi. The Intelligence Review (p. 62) now reveals that a small cyclotron, which the Russians had removed from Berlin, was installed at Sukhumi. Since cyclotrons, especially of a small size, are laboratory equipment, and are not needed in the actual production of atomic bombs or atomic materials, the conclusion may be drawn that the Russians established at Sukhumi a nuclear physics laboratory.

Werner Grothmann on electronuclear breeding of Pu-239 [Krotzky 2002]. For a discussion of the background and reliability of this source, see pp. 3396–3397.

[S. 40] Wichtig ist aber, dass dann später, als wir uns in die Forschung eingeklinkt hatten, auch versucht worden ist, Plutonium herzustellen, auch ohne einen Reaktor. Ich kann dazu nur sagen, das, was ich dazu heute noch weiß, habe ich erst ganz kurz vor Kriegsende erfahren und es sind auch nur einige Teile von dieser Sache, weil mich das ja auch nicht im Amt betraf, mit Ausnahme von besonderen Maßnahmen, die ich im Auftrag von Himmler persönlich übernehmen musste. Aber da hat mich auch niemand von den Fachleuten informiert, sondern ich hörte nur mal so Andeutungen.

[S. 41] Es war jedenfalls so, dass versucht worden ist, Plutonium zu erzeugen, ohne dass man den Reaktor hatte. In der Theorie war das möglich, wie man Himmler erklärt hatte, in der Praxis so gut wie unwahrscheinlich. Zum Beispiel fehlten dazu erst mal die Geräte. Es hat aber Versuche gegeben, im Labormaßstab, also da sind in kleinstem Maßstab Versuche gemacht worden, Plutonium herzustellen. Man muß sich das so vorstellen, dass die Ergebnisse, die man erzielen wollte, nur unvorstellbar geringe Mengen erbracht hätten, vielleicht so Milligramm oder noch weniger. Es ging ja erst mal auch nur darum zu sehen, ob die Theorie stimmt und ob das überhaupt klappen würde. Ich hörte dann mal, dass man das vor allem in Österreich versucht hatte, dass die Physiker aber enttäuscht waren, weil es eben nicht ging, Ich weiß nicht, woran es lag, das habe ich nicht erfahren, es gab aber dazu Besprechungen. Im Sommer 1944, als sich die Uran-Geschichte schon ordentlich entwickelt hatte, sind dann entschiedene Maßnahmen vorgenommen worden, weil es dann doch Hinweise daraufgegeben hatte, dass man Plutonium herstellen könnte, wenn auch mühsam und mit sehr geringen Mengen. Es hat dazu von Himmler den Auftrag gegeben, unsere technischen Möglichkeiten zu nutzen, um die ersten Geräte dafür zu bauen. Die Konstruktionszeichnungen dafür waren aber nicht von unseren Leuten. [...]

[p. 40] It is important, however, that later, when we were engaged in the research, attempts were also made to produce plutonium, even without a reactor. All I can say is that what I know about it today I did not learn until very shortly before the end of the war, and then only a few parts of this matter, because that did not concern me in office, except for special measures that I personally had to undertake on behalf of Himmler. But I was not informed by any of the experts about that, rather I only heard hints.

[p. 41] At any rate, it was attempted to produce plutonium without having a reactor. In theory this was possible, as Himmler was told, though as good as unlikely in practice. For example, the equipment was missing. However, attempts were made to produce plutonium on the laboratory scale, that is, on a small scale. One has to imagine that the results which one wanted to achieve would have only produced inconceivably small amounts, perhaps a milligram or even less. There was only time to see whether the theory was correct and whether it would work at all. I heard then that this had been tried especially in Austria, but that the physicists were disappointed because it just was not possible, I know I did not know what it was, but there were discussions about it. In the summer of 1944, when the uranium program had already been developed properly, decisive measures were taken, because there was evidence that plutonium could be produced, albeit with difficulty and in very small quantities. It was Himmler who commissioned us to use our technical capabilities to build the first machines for it. The construction drawings for it were not from our people. [...]

Außerdem hatte die Reichspost in der Nähe eine eigene ganz geheime Forschungseinrichtung, zu der ich aber nichts weiß. Die Maschinenanlage für die Plutonium- Sache ist von österreichischen Firmen und im Protektorat hergestellt worden. Das war so, weil es ja bessere Kontakte österreichischer Wissenschaftler zu ihren eigenen Firmen gab, die arbeiteten übrigens hervorragend. [...]

[S. 41] Der Betrieb der Anlage sollte so organisiert werden, daß wir die Einrichtung stellen und auch den Bau der unterirdischen Räume. Die Techniker dort sollten sie für uns betreiben und die fachliche Aufsicht hätten Ohnesorges Leute bekommen. [...]

Nach dem Krieg habe ich dann mal gehört, wir hätten Material für eine oder zwei Plutonium-Bomben gehabt. Ich kann dazu nur sagen, dass ich das nicht glaube. Ich bin ja in dem Thema nicht drin. Wir haben nach meiner Kenntnis dazu nichts gehabt. Ob andere Gruppen irgendwo etwas erzeugt haben, weiß ich nicht, ich weiß aber, wie unglaublich schwierig das alles war. [...]

Ob von den Österreichern noch was konkret zum Plutonium gemacht worden ist, kann ich mir eigentlich nicht vorstellen, obwohl man manchmal so Gerüchte hörte.

In addition, the Reichspost had its own very secret research facility nearby, but I do not know anything about it. The equipment for the plutonium matter was manufactured by Austrian companies and in the Protectorate. This was so because Austrian scientists had better contacts to their own companies, which did excellent work by the way. [...]

[p. 41] The operation of the facility was supposed to be organized such that we provided the facility and also the construction of the underground rooms. The technicians there should operate them for us and Ohnesorge's people would provide the technical supervision. [...]

After the war I heard that we had material for one or two plutonium bombs. I can only say that I do not believe it. I am not on that topic. We had nothing to my knowledge. Whether other groups produced something anywhere, I do not know, but I know how incredibly difficult it all was. [...]

I can't imagine whether the Austrians did anything concrete about plutonium, although one sometimes heard such rumors.

[Grothmann's description certainly sounds like electronuclear breeding. It agrees well with other sources here, such as the manufacture of cyclotrons in the Czechoslovakian Protectorate and Flerov's account of what may have been an electronuclear breeding facility in Silesia. (Details on both of those only came out after Grothmann's death, so his story appears to have been an independent confirmation.) The details remembered by Grothmann are also highly consistent with the physics of electronuclear breeding, even though Grothmann was not a scientist. Note that because of the extreme secrecy of the nuclear program, even Grothmann was unsure how much plutonium was produced by the end of the war.

As shown in Appendix C (p. 3020), numerous documents demonstrate that there was extensive work throughout the war on particle accelerators, which would have been highly suitable for electronuclear breeding. Please see all of those documents in Appendix C. A few additional relevant documents are presented on the following pages.]

D.7 Production of Other Potentially Nuclear-Related Materials

[During the war, Germany produced large quantities of materials that had non-nuclear applications, yet would also have been extremely useful for a nuclear weapons program. See Table D.1.]

Material	**Nuclear applications**	**Non-nuclear appl.**	**Wartime production**
Deuterium & heavy water (p. 4027)	Producing tritium, neutrons, & fusion; neutron moderator for fission reactor	Isotope labelling of molecules	At least ∼25 production plants
Lithium (p. 4090)	Producing tritium, neutrons, fusion	Processing ceramics, glass, metals	Hundreds of tons
Beryllium (p. 4096)	Neutron production/ reflection	Metal alloys	Many tons
Boron (p. 4104)	Neutron absorber	Producing ceramics, glass, metals	Large quantities
Graphite (p. 4110)	Neutron moderator for fission reactor	Rocket rudders	Tens of thousands of tons
Fluorine (p. 4118)	Uranium hexafluoride for enrichment	Industrial production	Thousands of tons
Aluminum (p. 4126)	Reactor fuel cladding, bomb casings	Metal structures, packaging	Thousands of tons
Calcium (p. 4132)	Thorium/uranium/ plutonium purification	Metal alloys	Thousands of tons
Nickel (p. 4138)	Resists corrosion by uranium hexafluoride	Batteries, alloys	Thousands of tons
Zirconium (p. 4142)	Reactor fuel cladding	High-temperature metals, ceramics	Many tons
Cadmium (p. 4148)	Neutron absorber	Nickel-cadmium batteries	Thousands of tons

Table D.1: Materials with both nuclear and non-nuclear applications that were mass-produced in wartime Germany.

[The following documents illustrate the large-scale production of these materials. From these documents, it is not possible to determine whether or how much of the material was used for nuclear applications, but clearly the materials were readily available if some quantity of them had been requested by a high-priority nuclear program.

Some sites were producing multiple nuclear-related materials at the same location. For example, I.G. Farben's Bitterfeld facility is documented to have been producing heavy water (p. 4050), graphite (p. 4110), aluminum (p. 4128), and calcium (pp. 4133, 4136); Bitterfeld may have produced other relevant materials as well.

Intriguingly, significant quantities of many of these nuclear-related materials were also shipped to Japan, Germany's wartime ally, along with at least 560 kg of (possibly enriched) uranium and other cutting-edge military technologies—see pp. 4094 and 4858.

Any nuclear-related production programs in wartime Germany would have had access to a larger labor pool than comparable programs in the United States. The population of the greater German-speaking world was equal to or somewhat greater than that of the United States at the time (Section 10.1.1). Including the populations of countries that were allied with or occupied by Germany, the total population of German-controlled territory was far larger than that of the United States.

Likewise, the gross domestic product (GDP, a measure of economic and industrial resources) of German-controlled territory was roughly comparable to or by some measures even greater than that of the United States (pp. 2100–2101).

Finally, the electrical power production of German-controlled Europe was fairly comparable to or even greater than that of the United States (pp. 2100–2104). Germany had access to power plants and fuel sources throughout most of Europe, and also built more during the war (e.g., pp. 3755–3759), so energy would not have been a limiting factor for nuclear-related production.]

A. Deuterium/Heavy Water

[Deuterium (D, a hydrogen isotope with one neutron, compared to normal hydrogen without any neutrons) is a great fusion fuel and can be used as a source for producing neutrons and tritium (T, a hydrogen isotope with two neutrons). In the form of deuterated or heavy water (D_2O), it is also an excellent neutron moderator for fission reactors.

According to official histories, Germany never even got a small prototype fission reactor operational before the end of the war, and only used heavy water for scientific research purposes. Moreover, according to official histories, heavy water was only produced in significant quantities at the Norsk Hydro hydrogen factory in Vemork, Norway, which was famously attacked by Allied forces and the Norwegian Resistance and forced to shut down.

In fact, documents indicate that heavy water production facilities for the German nuclear program were known or reported to be located at sites all over German-occupied Europe (see map on p. 4030):

1. Vemork, Norway (pp. 4031–4039).
2. Såheim, Norway (p. 4040).
3. Notodden, Norway (p. 4041).
4. I.G. Farben Leuna Werke, low-pressure production plant (pp. 4042–4050).
5. I.G. Farben Leuna Werke, high-pressure production plant (pp. 4042–4050).
6. I.G. Farben Bitterfeld (pp. 4050–4051) [Karlsch 2005, p. 110; Sadovsky 2011b].
7. I.G. Farben Halle (pp. 4052–4055).

8. Kiel, probably adjacent to the Deutsche Werke Kiel (pp. 4056–4061).
9. Dräger Werke, Lübeck (pp. 4062–4063).
10. Müggenberg (pp. 4064–4065).
11. Chemische Fabrik Griesheim-Elektron, Frankfurt am Main (pp. 3678–3680, 4066–4067).
12. Berlin plant (p. 4068).
13. Linde plant, Munich (p. 4068).
14. Montecatini plant, Sinigo-Merano, Italy (p. 4069).
15. Montecatini plant, Cotrone/Crotone, Italy (p. 4069).
16. I.G. Farben Auschwitz in Poland (pp. 4069, 4452).
17. Plant near the Schmiedeberg (now Kowary, Poland) uranium mine (p. 4069).
18. Plant near Breslau (now Wrocław, Poland; pp. 4070–4071).
19. Weer, near Wattens, Tyrol, in the Austrian Alps (pp. 4072–4077).
20. B9 Quarz underground complex near Roggendorf and Melk, Austria (p. 4078–4079).
21. Degussa plant at Rheinfelden, Austria (pp. 4080–4081).
22. Austrian Chemical Works plant at Weissenstein, Austria (pp. 4080–4081).
23. Siemens and Halske plant in Lehesten (pp. 3689, 3696, 4080).
24. Bayrische Stickstoffwerke in Piesteritz (pp. 4082, 4452–4453).
25. Pardubice/Wesser, Czechia (pp. 3446, 4082–4083).
26. Other possible locations (pp. 4084–4086).

The documents in this section show that Germany was producing large quantities of heavy water in a very determined fashion at numerous plants all over Europe, despite the difficulties of Allied bombing and the urgent wartime needs to produce other materials and products.

The existence of this massive, high priority, highly secretive heavy water production program strongly suggests that one or more fission reactors may have actually been operational during the war. At the very least, it seems to indicate that Germany was trying to get reactors operational as soon as possible. Germany may have also needed significant quantities of deuterium/heavy water for electronuclear breeding of fission fuel and/or for fusion fuel production.

Moreover, the fact that the files on most of those heavy water plants are still classified (e.g., pp. 4053–4055) also suggests that the German program got much further than we have been told.

While some historians have claimed that the German nuclear program was unwise to choose heavy water instead of graphite as a reactor moderator, the actual historical and scientific record suggests otherwise.

First of all, it is far from certain that the German program did exclude graphite. For example, I.G. Farben's Bitterfeld facility was mass-producing both graphite (p. 4110) and heavy water (p. 4050) as well as other nuclear-related materials (pp. 4128, 4133, 4136). Similarly, Griesheim plants were producing both graphite (pp. 4114–4116) and heavy water (pp. 4066–4067), with other nuclear-related facilities such as Degussa in the same area [Hayes 2004; Nagel 2016]. Graphite was also mass-produced at the Siemens Plania Werke in Racibórz/Ratibor, Poland (pp. 4110–4114), near a reported heavy water plant at Auschwitz (pp. 4069, 4452) and reported uranium enrichment plants at Opava and Ostrava (p. 3749).

It may well be that the German program was aware that graphite could be used as a moderator but preferred heavy water for several reasons:

- The "moderating ratio," the ratio of how strongly a moderating material slows down neutrons vs. how strongly it absorbs neutrons, is ∼25–100 times larger for heavy water than for graphite (depending on the purity of the heavy water). Since heavy water is far more effective than graphite at slowing neutrons without absorbing them, much less moderator and/or natural uranium would be required for a reactor to achieve criticality, or the reactor could be more easily loaded with other neutron-absorbing materials such as lithium for tritium production. Because of these advantages, the United States built five heavy water reactors at the Savannah River Site in the 1950s and used them to breed over 36,000 kg of plutonium during the Cold War.[12]

- Using heavy water would avoid "Wigner's disease," in which irradiated graphite swells, stores/releases large amount of energy, and creates problems in a reactor, as caused major headaches in both the United States (diagnosed by Eugene Wigner) and the Soviet Union (e.g., the January 1949 Chelyabinsk Reactor A accident that shortened Igor Kurchatov's life) [Kojevnikov 2004, p. 151; Bruce Cameron Reed 2019, pp. 260–261; Rhodes 1995, p. 277].

- Graphite is flammable and could cause or contribute to a catastrophic reactor accident, as in the 1957 Windscale reactor fire in the U.K. nuclear weapons program [Lorna Arnold 2007; Mahaffey 2014, p. 176].

- While being used as a moderator for fission reactions, heavy water will simultaneously breed tritium. Further tritium can be bred by inserting lithium into the heavy water reactor (which can spare more neutrons for that purpose than a graphite reactor could, since the moderating ratio of heavy water is much higher). For example, the five heavy water reactors at the U.S. Savannah River Site produced around 200 kg of tritium during the Cold War [Høibråten 2020]. There is evidence that the wartime German program wanted fusion fuels such as tritium for (a) neutron initiators in fission bombs, (b) fusion neutron boosting in fission bombs, and (c) fusion fuel for a megaton-level H-bomb (Section D.9).

- Using heavy water for reactors would leave all of Germany's graphite available for other urgent applications, such as electrodes, rocket exhaust steering rudders, and steel production.]

1. Vemork, Norway

Heavy water production at Vemork for the years 1934/35–1944/45 [courtesy of Gunhild Lurås, Norwegian Industrial Workers Museum archive, Vemork]

Time period	D_2O produced
1 July 1934–30 June 1935	37.44 kg
1 July 1935–30 June 1936	81.50 kg
1 July 1936–30 June 1937	89.70 kg
1 July 1937–30 June 1938	77.35 kg
1 July 1938–30 June 1939	104.92 kg
1 July 1939–30 June 1940	20.35 kg
1 July 1940–30 June 1941	287.75 kg
1 July 1941–30 June 1942	870 kg
1 July 1942–30 June 1943	1179 kg
1 July 1943–30 June 1944	487 kg
1 July 1944–30 June 1945	0 kg

[According to the Vemork production reports, the produced heavy water had a typical purity of 99.6% during this period.

According to the Vemork archives, a significant quantity of deuterium was also produced and shipped to Germany in forms other than heavy water—as deuterium gas, deuterated ammonia, etc. From the surviving records, it is unclear what the total quantities of deuterium were.

The Vemork archives show that Norwegian plants at Såheim (p. 4040) and Notodden (p. 4041) were also producing and shipping heavy water and/or deuterium to Germany. The surviving records do not indicate how much was produced and shipped by those plants.

In December 1939, Vemork received an order from I.G. Farben for 10 kg of heavy water, presumably in order to test its quality. (Up to that time, Vemork had only sold a total of 40 kg of heavy water since beginning production.)

In January 1940, Vemork then received an order from I.G. Farben for 2000 kg of heavy water.

Germany invaded Norway on 9 April 1940 and took over Vemork in early May 1940.

Paul Harteck, Hans Suess, Karl Wirtz, Kurt Diebner, and other German and Austrian scientists worked closely with Vemork to increase its heavy water production. Ongoing orders for heavy water were placed by the Heereswaffenamt (Army Ordnance Office) in Berlin-Dahlem.

Thus Germany had a strong interest in obtaining large amounts of heavy water from 1939 onward, consistent with its strong interest in obtaining large amounts of uranium from 1939 onward (see for example p. 3998).

After several attacks and acts of sabotage by the British Special Operations Executive (SOE) and the Norwegian Resistance 1942–1944, heavy but unsuccessful Allied aerial bombing in November 1943, and the threat of further Allied bombing, in 1944 the Vemork heavy water production equipment was disassembled and sent to Germany. It is unclear if or where it was reassembled and restarted.]

G-188. Paul Harteck, H. Suess, Konsul Schoepke, N. Stephansen, and J. Brun. Minutes of the Meeting at Norsk Hydro. 27 May 1942.

Brief notes on proposed catalysts, procurement of a ventilator, mixers, preheaters, coolers, steel flasks, etc. Plant again in operation since May 12 and about 60 kg D_2O now on hand.

G-262. Paul Harteck. Status of Deuterium Production. 1944.

Progress of D production in Norway and difficulties resulting from sabotage and bombing are reported for the period from 1941 to 1943 when production was discontinued. Suitability of various procedures for production of D in Germany are discussed. Procedures proposed use either distillation of equilibrium exchange ($H_2 + HDO \leftrightarrow HD + H_2O$; or $H_2S + HDO \leftrightarrow HDS + H_2O$.)

William Casey. 1988. *The Secret War Against Hitler.* Washington, DC: Regnery Gateway. p. 54.

In April 1945, the dismantled high concentration plant was found in Bavaria, together with uranium and heavy water on the brink of going critical, lacking about 700 liters of additional heavy water. The Germans were never able to get out of Norway much more than half the heavy water they needed. Nobel prize-winner [Eugene] Wigner, one of the physicists driven out of Germany, had in 1942 told the American government that the Germans would produce a nuclear weapon in two years. If Vemork had been allowed to maintain its rate of heavy water output through 1943 and 1944, he might have been right.

[Was Casey referring to Diebner's pile that had been evacuated to Bavaria? Or the Haigerloch pile (not in Bavaria)? Or something else?]

LOCO personal to Groves for Smith from Furman signed Eisenhower E 41876.

Have in Paris approximately 4½ tons of metal in cubes 2 inches on side solidly packed in boxes weighing about 100 pounds. Lansdale has seen this material. No unusual activity according to Goudsmit but will check with Coumter as soon as possible. Not immersed in acid. Apparently no shipping difficulty. Shipping address has been given as Oak Ridge. Wire immediately confirming this, as previously requested.

1½ tons of acid approximately in 50 gallon drums is in Paris. Care necessary in handling as drums are tight but not strong. Diteshiem or Warner to accompany shipment on return to Manhattan District. Warner completing details of shipping arrangements. If you have another officer in mind to be sent from States please make him available. M insistent that metal is likely to go to Montreal. Therefore he says it might as well be shipped to him. Have told him that easiest shipping arrangements to get material off continent are being made which from here definitely means the States. M interested in receiving the 30 or more tons of acid in various concentrations being picked up in Hartz Mountains. Obtain shipping instructions on this. Lane has some details as to value, which are also contained in Smyth's ALSOS report.

IN REPLY REFER TO

21 August 1945

MEMORANDUM to: Major W. E. Kelley.

1. This will confirm telephone request made by the undersigned on 21 August 1945 for you to ship four barrels of P-9, which were represented by Samples X-1, X-2, X-3 and X-4, to Major M. J. Barnett, Morgantown Ordnance Works, Morgantown, West Virginia, Attention: Dr. J. A. Monier.

2. The P-9 contained in these four barrels is of very high concentration and every precaution should be taken to prevent any harm coming to it during shipment.

3. It is requested that armed guard, hand-to-hand receipt, express service be used in shipping the four barrels and that they be carefully checked before shipment to make sure that they are in good condition and will stand the trip without leakage.

HARRY S. TRAYNOR,
Major, Corps of Engineers.

Subject: Heavy Water.

MEMORANDUM to General Groves:
THRU Colonel Shuler and Colonel Derry.

1. The following teletype regarding the heavy water in New York has been received from Major Traynor:

"Drums X-1 through X-4 were reworked at Morgantown and yielded 3150 lbs. specification grade P-9 which was lumped in with our production to fill existing commitments. Other 35 drums in New York contain water very low in P-9 content which if completely processed would yield only about 115 lbs. pure P-9. Trail is only plant in operation for processing this material and special arrangements would be required to protect it against freezing if shipped before next spring. All presently known commitments for P-9 filled by end October 1945. Monthly production of approximately 1100 lbs starting with November 1945 is uncommitted."

2. Colonel Derry has informed Dr. Bradbury that the four drums of pure heavy water have been processed and are not available. It is recommended that the appropriate storage space be secured in New York and that the material be held until spring for processing.

Craven & Cate. 1951. *The Army Air Forces in World War II.* Vol. 3, pp. 176–7, 828.

Their shortsightedness proved painful on the 12 May [1944] mission and during the numerous attacks which followed. On this occasion, 15 combat wings involving 935 heavy bombers, escorted by Eighth and Ninth Air Force and RAF fighters, took off for what was to prove a historic operation.[169] [...] More than 800 heavies attacked, dropping 1,718 tons on the synthetic oil plants at Zwickau, Merseburg-Leuna, Brüx, Lützkendorf, Böhlen, and other cities. [...] Certainly the professed objective of the mission was attained: the German Air Force had reacted vigorously to the attacks on oil plants and had suffered severe losses. More important in the long run was the fact that all of the targets were damaged, some of them very heavily. Brüx, Böhlen, and Zeitz were knocked temporarily out of operation, and the bombing at Merseburg-Leuna happened to destroy a building in which experiments were being conducted with heavy water for Germany's atomic-bomb project.[170] It was an excellent mission, despite the heavy loss of bombers, and an auspicious opening of the Eighth Air Force campaign to deny the Germans oil.

Report of Raid on Merseburg

The attack took place 12 May 1944. Not only Merseburg but Lutzendorf (oil refinery), Zwicau (airfield), Brun (oil refinery), Zeitz (oil refinery), and Bohlen were bombed.

There were 814 bombers on this mission. The losses were 5.2%, which is high. Heavy resistance was encountered over the latter locations which are in Czechoslovakia, very light resistance was encountered over Merseburg. The greatest resistance was put up at Lutzendorf.

The IGF Leuna Plant is located at Merseburg. This is the largest IGF plant and is made up principally of ammonia and nitrogen fixation plants.

MEMO FOR THE FILES

Concerning a Visit with Respect to Heavy Water Matters

Visitors: Prof. Gerlach, KWI für Physik, Berlin
Prof. Bonhoeffer, Leipzig

Others present: Director Dr. Bütefisch, Leuna
Director Dr. Herold "
O. I. Keinke "
Dr. Orlicek (temporary) "
Dr. Elbel "

(N.B: First paragraph merely says that transferring NUCLEAR PHYSICS matters from Esau to Gerlach would make no change in the picture whatever. Heavy Water matters would be settled between Gerlach and Dr. Herold.)

The second question to claim attention was the business of finding a suitable location for the High Concentration Installation to be built "through Leuna." Provision was duly made for setting up the apparatus in WEIDA. Because the problem was solved by the PTR (German Bureau of Standards for Physical Problems) and because of difficulties subsequently arising over supplying the necessary energy, WEIDA is now no longer being considered as the site for this installation. Also the suggestion to set up the installation in the SEEBURG (coal) bunker requires no further discussion for the reason that the place available for such installation is not great enough. Combining the apparatus with that of I. G. Farben's appears to imply great danger for the Farben installation in view of the bombing in Norway with the consequent difficulty in keeping the PURPOSE OF CONSTRUCTION OF SUCH AN INSTALLATION SECRET (in this connection Dr. Elbel called attention to rumors current in Norway about the use of heavy water); so that this simple solution is not being considered. Dr. Bütefisch at the instance of O. I. Keinke suggested setting up the apparatus in the closed-down plant in WYRO,/O. S. (Upper Silesia); for, there

1. there exists a relatively high degree of security against attack,
2. danger to other production is ruled out.

Besides, there is a larger electrolytic apparatus there, so that it is certainly possible to supply electrical energy without difficulty; perhaps it may even be possible to use the RECTIFIER already there for our apparatus. He said that supplying further necessary energy should be clarified after O. I. Keinke and Dr. Elbel make a trip there. To house the apparatus, it was Buildings 18, 19 and 20 which house the electrolytic apparatus, could be used. This suggestion was accepted by all present as especially auspicious. Use of the Plechkranz* electrolysis cells is out of the question because of the high specific volume of fluidity of this apparatus.

*Plechkranz: Dr. Hertzfeld, head of the Physics Dept. of Cath. U., told me over the phone that this term is not a scientific one and that it was his guess that it is a proper name. Trans: EFR

SECRET

SECRET

Concerning a Visit with Respect to Heavy Water Matters - Leuna Werke 28 Feb 44
(Cont'd.)..................

The third point discussed was the matter of prerequisite products for the High Concentration installation. First of all, the WYROW High Concentration apparatus would be fed with the pre-concentrates from NORSK HYDRO, WERK VEMOR and SAAHEIM. The concentrates are at present being drawn off in Norway and then sent to I. G. (N.B: Farben, undoubtedly: Trans.) but how this is done was not further described. The concentrates then must still be distilled in Germany and analysed because NORSK HYDRO cannot at this time make the necessary density determinations. It was suggested storing the products in various dispersed warehouses of the Ammonia Works (N.B: I'm quite certain that this refers to I. G. Farben and it is also quite clear from the context: Trans.) The work being done at present is putting into operation the second small enrichment series of the High Concentration apparatus for further work on these products.

Nothing definitive can be said at the moment about the possibility of employing additional electrolytic apparatuses for furnishing pre-concentrates. As is well known, provision has been made for the immediate completion of the Sinich electrolysis installation near MERAN (N.B: in Italy: Trans.) which should be prosecuted with all dispatch.

The enrichment procedure suggested by Prof. HARTECK and Dr. SUESS, which is being tested at the present time in LEUNA, is out of the question for the duration of the war, so far as production of pre-concentrates is concerned, because of the high cost of construction. Consequently, the procedure for vacuum-water distillation procedure recommended by Prof. HARTECK was taken up by O. I. KEINKE and Dr. ORLICEK. The first rough estimate of the economic feasibility of this showed that with the same production cost of the pre-concentrates (themselves), the cost of installing such an apparatus would probably amount to only a tenth of the cost involved in the Harteck-Suess apparatus, so that construction of such an apparatus within the foreseeable future is a possibility. The possibility of such a process depends, however, on obtaining a really efficient distillation column based upon the least possible current-resistance. To this end, experiments must be promptly undertaken in Leuna, for which it is necessary to obtain a vacuum-distillation column of approximately 40 m. in height and 600 mm diameter.

Two columns mentioned above could, according to theoretical determinations, furnish up to 1/4 ton Heavy Water as a 1% solution. Dr. Orlicek still has misgivings about the possibility of operating such a column because through the change-over from H_2O and D_2O to HDO and vice-versa very many heat-tones arise in it, which must be transferred, as is the case with the heat exchange required for the rectification (N.B.: elimination through distillation-?) of D_2O. Prof. Bonhoeffer promised to determine the magnitude of these heat-tones.

Herrn Professor Dr. W. Gerlach

(1) Berlin - Dahlem
Boltzmannstraße 20

Sehr geehrter Herr Professor!

Aus einem Durchschlag Ihres Briefes vom 28.6.44 an Herrn Dr. Ambros, für dessen Zusendung ich bestens danke, ersehe ich, daß die Reinigungsanlage nunmehr endgültig nicht nach Falkenhagen kommen wird.

Unverständlich ist mir aber Ihre Bemerkung, daß nach dieser ablehnenden Entscheidung wieder eine neue Stelle gesucht werden muß. Ich war bisher der Auffassung, daß, falls Falkenhagen nicht als Ort für diese Apparatur in Betracht kommt, die ursprüngliche Absicht zur Ausführung gelangt, nämlich, sie im KWI für Physik unterzubringen. Hat sich an dieser Sachlage etwas geändert, was mir vielleicht nicht zur Kenntnis gelangt ist? Für eine Benachrichtigung darüber wäre ich Ihnen sehr dankbar; ebenso für einen Bescheid, wie weit die ganze Angelegenheit überhaupt gediehen ist. Wir haben uns ja damals auf Ihr Drängen bereit erklärt, die Erstellung der Anlage zu übernehmen, mußten aber zur Bedingung machen, uns auf ein Jahr eine Anzahl Schlosser durch Rückholung aus der Wehrmacht zur Verfügung zu stellen. Die Namen derselben sind Ihnen seinerzeit mitgeteilt worden.

Ich habe auch bereits meinen Mitarbeiter, Herrn Dr. Barkow, kürzlich beauftragt, seine längere dienstliche Anwesenheit in Berlin gelegentlich dazu zu benutzen, Herrn Dr. Diebner aufzusuchen und sich nach dem Stand der Angelegenheit zu erkundigen. Ich möchte nicht versäumen, Sie von diesem Schritt zu unterrichten.

In der Hoffnung, daß Sie inzwischen längst wieder wohlauf sind, grüßt Sie vielmals

Ihr ergebener

P. Herold

3 May 1945

SUBJECT: (1) Interrogation of Dr. Herold, Director of Research (25 April) and Dr. Arnold Elbel of the Ammoniakwerk Merseburg, Leuna-Werke (26 April)
(2) Visit to the Physico-Chemical Institute and the Physical Institute, University of Leipzig (26 April)

SUBJECT: I:

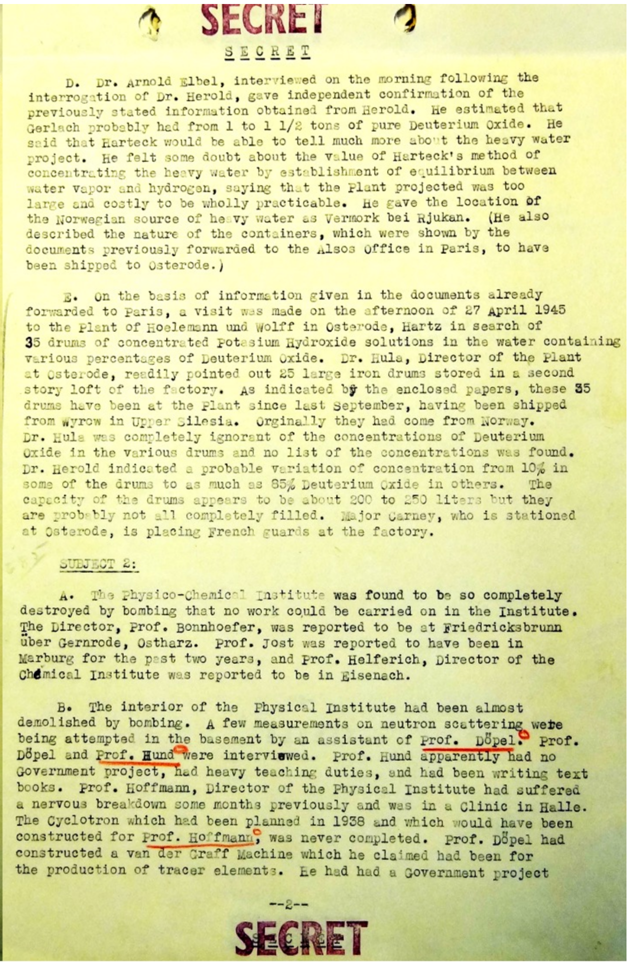
A. Dr. Herold was questioned on the basis of documents relating to a project for the concentration of heavy water by means of electrolysis followed by a process involving the repeated establishment of equilibrium between hydrogen and water vapor in successive steps, as described in the documents previously forwarded to the Alsos office in Paris.

B. It was originally planned to obtain a 1% solution of Deuterium Oxide by means of electrolysis carried out at the Montecatini-Elektrolysewerken, Merano, Italy. The two plants involved are located at Marlengo in the outskirts of Merano, and at Sinico, three or four kilometers from Merano. It was originally estimated that the Plant operated in connection with the Nitrogen plant could produce 100 tons per year of 1% Deuterium Oxide solution. It was found that loss by evaporation would probably cut the production at least in half. Moreover, transportation difficulties were serious. Therefore in February or March 1945, Montecatini was instructed to abandon the work. The two leading men apparently involved in the Montecatini work were Director Orsoni and Prof. Argentieri. The sources of heavy electric current available at the Bitterfeld Plant of the Ammoniakwerk and possibly Norwegian sources, would probably have provided a substitute for the Montecatini production. This point was not clarified by the two men interrogated. The concentration of the dilute heavy water would have been carried out at Leuna but the bombing of the plant prevented all work beyond a preliminary experimental setup.

C. Gerlach desired an annual production of 10 tons of Deuterium Oxide from the Leuna plant but Herold felt that 2 or 3 tons would have been all that they could produce. It is to be noted in the report dated 21 December 1944 and enclosed herewith together with additional material pertaining to heavy water production, that concentration of the material was contemplated in a Monastery in Stadtilm. Herold estimated that Gerlach probably had about one ton of pure Deuterium Oxide at the present time.

- 1 -

SECRET



SECRET

S E C R E T

D. Dr. Arnold Elbel, interviewed on the morning following the interrogation of Dr. Herold, gave independent confirmation of the previously stated information obtained from Herold. He estimated that Gerlach probably had from 1 to 1 1/2 tons of pure Deuterium Oxide. He said that Harteck would be able to tell much more about the heavy water project. He felt some doubt about the value of Harteck's method of concentrating the heavy water by establishment of equilibrium between water vapor and hydrogen, saying that the Plant projected was too large and costly to be wholly practicable. He gave the location of the Norwegian source of heavy water as Vermork bei Rjukan. (He also described the nature of the containers, which were shown by the documents previously forwarded to the Alsos Office in Paris, to have been shipped to Osterode.)

E. On the basis of information given in the documents already forwarded to Paris, a visit was made on the afternoon of 27 April 1945 to the Plant of Hoelemann und Wolff in Osterode, Hartz in search of 35 drums of concentrated Potassium Hydroxide solutions in the water containing various percentages of Deuterium Oxide. Dr. Hula, Director of the Plant at Osterode, readily pointed out 25 large iron drums stored in a second story loft of the factory. As indicated by the enclosed papers, these 35 drums have been at the Plant since last September, having been shipped from Wyrow in Upper Silesia. Orginally they had come from Norway. Dr. Hula was completely ignorant of the concentrations of Deuterium Oxide in the various drums and no list of the concentrations was found. Dr. Herold indicated a probable variation of concentration from 10% in some of the drums to as much as 85% Deuterium Oxide in others. The capacity of the drums appears to be about 200 to 250 liters but they are probably not all completely filled. Major Carney, who is stationed at Osterode, is placing French guards at the factory.

SUBJECT 2:

A. The Physico-Chemical Institute was found to be so completely destroyed by bombing that no work could be carried on in the Institute. The Director, Prof. Bonnhoefer, was reported to be at Friedricksbrunn über Gernrode, Ostharz. Prof. Jost was reported to have been in Marburg for the past two years, and Prof. Helferich, Director of the Chemical Institute was reported to be in Eisenach.

B. The interior of the Physical Institute had been almost demolished by bombing. A few measurements on neutron scattering were being attempted in the basement by an assistant of Prof. Döpel. Prof. Döpel and Prof. Hund were interviewed. Prof. Hund apparently had no Government project, had heavy teaching duties, and had been writing text books. Prof. Hoffmann, Director of the Physical Institute had suffered a nervous breakdown some months previously and was in a Clinic in Halle. The Cyclotron which had been planned in 1938 and which would have been constructed for Prof. Hoffmann, was never completed. Prof. Döpel had constructed a van der Graff Machine which he claimed had been for the production of tracer elements. He had had a Government project

--2--

SECRET

S E C R E T

which he claimed was for fundamental research and not for war purposes. His attitude was hostile and no great importance can be attached to his claims. However the apparatus was destroyed by bombing soon after its completion and the few fragments of it left visible provided confirmation of this portion of Prof. Döpel's statement. It was further claimed that the Cyclotron had been projected simply for the purpose of fundamental research.

C. The interrogation of the Physicists was carried out in collaboration with Maj. Warren and Maj. Williams, R.E.M.E. of the CIOS who had arrived at the Institute just before Lt. Kunisch and the writer for the purpose of questioning Hund about nuclear physics.

Pentagon Bldg.,
Washington, D. C.

Dear Malcolm:

I got the following information, which is probably not new. Could you let me know how correct it is?

The Russians have removed the principal installations from the German Leuna Werke:

the synthetic ammonia plant, 750 tons/day, to Gorki near Moscow;
the synthetic oil plant, 250 tons/day, to Donetz;
the heavy water plant to the Waikal Lake, S. E. Siberia.

Russian Radar research uses a wavelength of 8 milimeters.

How are your plans for the summer shaping up? I had a good time at the Washington meeting.

Best greetings to everyone, in the office and at home.

Yours,

S. A. Goudsmit

Dr. Samuel A. Goudsmit
Department of Physics
Northwestern University
Evanston, Illinois

Dear Sam:

I have your letter of the 19th, and on checking our files I find that it apparently represents new information. We know, of course, that the Leuna Werkes have been evacuated to Russia but did not know where. I have not, however, checked with Eurasian Branch.

I presume that the Waikal Lake that you mentioned is actually Baikal Lake.

Curiously enough it is just reported in the Russian press that a certain V.K. Arkadev has been working with millimeter radio waves but aside from reporting "great success" nothing specific is given. Eight millimeters is getting right down in to the water vapor absorption bands. We know of course that the Russians have at least 40 of our 10 centimeter radars.

My plans for the summer are still waiting on the Military Liaison Committee which has taken some action on my request, but has not yet told me just what the action is. If their action is negative I will then take steps to use the consulting "racket." I saw Bacher at a cocktail party after you had left and he seemed to think the consulting technique would be a good one. I take it you had talked to him. Greetings from all of us.

Yours,

Malcolm

Figure D.495: Samuel Goudsmit to Malcolm Henderson. 19 May 1947 [NARA RG GOUDS, Entry UD-7420, Box 3, Folder "Historian's Office Inventory Control Job Goudsmit Box 4 Folder 4"]. "The Russians have removed the principal installations from the German Leuna Werke: ...the heavy water plant."

6. I.G. Farben Bitterfeld

A. S. Sadovsky. 2011b. Heavy Water. History of One Priority. Part 2. https://www.academia.edu/39286335/Heavy_water_History_of_one_priority_Part_2_031e

Somewhat earlier 4 September [1945] it was formulated the decree of the State Defense Committee 9967ss, which ordered to him:

> “c) That the research and test works on making product 180 [heavy water] by electrolytic separation, isotopic exchange, and distillation methods be organized in GSNII-42, at the Moscow Electrolysis Factory, and in the Karpov Physical-Chemical Institute. That for this purpose be used the installations found at the German chemical plants in Leuna Werke and Bitterfeld. <...>
>
> 4. It shall be the responsibility of the Narcomkhimprom [eng: People’s Commissar for the Chemical Industry] (Cde. Pervukhin) and USSR NKO [eng: People’s Commissariat of Defense] (Cde. Khrulev) to provide evacuation from Germany <...> and transportation to Narcomkhimprom facilities <...> of the following equipment:
>
> a) distillation tower and the pilot-scale electrolyzer from the Bitterfeld plant within the period from 10 September till 20 September 1945;
>
> b) small pilot plant from Leuna Werke factory within the period from 10 September till 20 September 1945;
>
> c) big pilot plant from Leuna Werke factory within the period from 10 September till 20 September 1945;
>
> Cde. Pervukhin is to send to the place one of his deputies to exercise control over dismantling of the specified equipment, its repair if necessary, ensure its complete package and oversee its entrainment at factories as well as at the Lvov storage terminal.”

Figure D.496: There was a heavy water production plant at I.G. Farben Bitterfeld during the war [Karlsch 2005, p. 110; Sadovsky 2011b]. (This is a later photograph showing part of the Bitterfeld chemical production complex.)

7. I.G. Farben Halle

7 June 1946. Recruitment of German Scientists; Heavy Water Production at Halle. Strategic Services Unit, Top Secret report [NARA RG 319, Entry NM3-85M, Box 51, Folders 926136–926139].

[See pp. 4053–4054.]

U.S. intelligence card catalog [NARA RG 319, Entry A1-84E, Box 124].

[See p. 4055.

U.S. intelligence cover pages and card catalog entries show that there was a heavy water production plant at Halle, but documents about the plant are still classified and unavailable to the public. Why?

Halle is close to Leuna/Merseburg. It is possible that the referenced Halle heavy water plant was the same as one of the Leuna Werke heavy water plants, but most likely it was a separate plant. That entire region was covered with chemical plants.]

8. Kiel

Charles Chamberlain. Reveal Allied Capture of Nazi Atom Factory. *Chicago Daily Tribune.* 9 August 1945 p. 4. http://archives.chicagotribune.com/1945/08/09/page/4/article/reveal-allied-capture-of-nazi-atom-factory/

KIEL, Germany, Aug. 8 (AP)—The largest heavy water plant in Germany, where Nazi scientists were working feverishly to perfect an atomic bomb, was captured almost intact by the allies three months ago in a heavily wooded section four miles from Kiel.

Cobwebs of plastic pipes connected eight huge vats holding thousands of gallons of plain water for processing into heavy water.

I stumbled onto the factory two weeks after it was taken over by American and British technicians. Altho they gave me freedom to roam around the grounds, I was called on the carpet the next day for entering without authority from high officials and was required to pledge not to reveal what I had seen until it was released. Altho the race to perfect the bomb was led by American and British experts, the Germans had made great strides and were catching up. The war against Germany ended just in time.

Charles Chamberlain. Allies Beat Nazis By Narrow Margin in Atomic Race. *Harrisburg Telegraph.* 9 August 1945 p. 6.
https://www.newspapers.com/article/harrisburg-telegraph/1961441/

KIEL, Germany, Aug. 9, (AP)—A race against time was won by the Allies by a narrow margin three months ago when the largest heavy water plant in Germany, where Nazi scientists labored furiously to perfect an atomic bomb, was captured intact.

It may now be disclosed that the Allies were so concerned over possible German progress with the bomb that they planned a bold mass parachute attack on Kiel as early as last March to take the experimental station, just outside this base.

The plan was dropped only after the successful Allied crossing of the Rhine, this correspondent learned.

The Kiel plant, captured almost intact three months ago and turned over to British and American specialists, was buried in a camouflaged concrete vault on a wooded hillside and contained eight vats for the manufacture of "D-2O," or heavy water—used in one of the possible processes for producing atomic bombs.

Cobwebs of connecting plastic pipes and files recording the experiments were destroyed by sabotage before the Allies arrived.

The extent of the Nazis' atomic discoveries remains a top secret. But they were making great strides and were catching up. The European war ended just in time.

Among the secret weapons in production at the factory were acoustics torpedoes driven by "ingolene," a fuel described by some sources as 800 times as powerful as high octane gasoline.

[See also:

Charles Chamberlain. Germans' Bomb Plant Located: Nazis Worked Hard on Atomic Device. *San Bernardino Sun.* 12 August 1945 p. 3. https://cdnc.ucr.edu/cgi-bin/cdnc?a=d&d=SBS19450812.1.3

Charles Chamberlain. Atom Race Won By Extremely Narrow Margin. *Ogden Standard Examiner.* 13 August 1945 p. 9. https://newspaperarchive.com/ogden-standard-examiner-aug-13-1945-p-9/

According to Chamberlain, "the largest heavy water plant in Germany" was located approximately four miles from central Kiel, was part of a larger factory that also produced torpedoes, and was hidden in a large concrete bunker buried in an adjacent "heavily wooded hillside." See pp. 4059–4061 for the likely location. Can any remains of this heavy water plant be found now?

As Chamberlain stated, many World War II German torpedoes were powered by "Ingolene," or concentrated hydrogen peroxide. Concentrated hydrogen peroxide was also used as propellant for some rockets and was indeed quite potent, though not far more powerful than gasoline. Chamberlain appears to have heard incorrect information on that point.

Chamberlain specifically remarked that the heavy water plant used a large amount of plastic pipe. While plastic pipe is very common now, it was relatively new and much less common at that time (see p. 643). It would have been used to avoid problems with corrosion and to keep the heavy water as pure as possible.

Chamberlain mentioned that the heavy water plant was partially damaged and its files destroyed or removed by Germans before Allied forces reached the plant.

Chamberlain also reported (based on what he saw and what he heard from Allied forces at the Kiel heavy water plant) that "Nazi scientists were working feverishly to perfect an atomic bomb" and that "The extent of the Nazis' atomic discoveries remains a top secret. But they were making great strides." Chamberlain made it clear that his description of the advanced state of the German nuclear program came directly from Allied investigators, not just his own opinions: "the Allies were so concerned over possible German progress with the bomb that they planned a bold mass parachute attack on Kiel as early as last March to take the experimental station."

The sequence of events behind Chamberlain's reports appears to be:

1. Chamberlain said that he "stumbled onto the factory two weeks after it was taken over by American and British technicians," so he probably discovered it in early or mid-May 1945.

2. Chamberlain was promptly reprimanded by Allied officials for even visiting the heavy water plant—he "was called on the carpet the next day for entering without authority from high officials." That censorship explains why Chamberlain did not publish any articles about the heavy water plan in May 1945.

3. In Allied countries, nuclear-related news articles were commonly censored during the war, up until the public announcement of the Hiroshima bombing. After widespread media reports about Hiroshima and the unveiling of the U.S. nuclear program, Chamberlain presumably thought he could finally report what he had learned in May 1945 regarding the German nuclear program. That explains why his first articles on this topic appeared in August 1945.

4. While it had become permissible to reveal (some) information about the U.S. nuclear program, apparently most details about the former German nuclear program were still closely guarded and publicly denied. Since Chamberlain's reports of this otherwise secret Kiel heavy water production facility and his description of the advanced state of the German nuclear program somehow slipped through censorship and got published in August 1945, he was likely reprimanded for a second and final time by government censors and/or his own newspaper employers. He does not seem to have ever mentioned the Kiel heavy water plant again.

5. In fact, when Chamberlain published an article about the Vemork heavy water plant in February 1946 (p. 4058), he made no mention of the Kiel heavy water plant that he had seen with his own eyes, even though it would have been relevant to the article. He also downplayed the state of the German nuclear program that he himself had reported only six months earlier was quite advanced.

6. The existence of the Kiel heavy water plant and Allied plans to attack it in March 1945 because the German nuclear program was so advanced appear to be historical facts that Allied governments buried in 1945 and that remain buried to this day.]

Charles Chamberlain. Germans Failed to Split Atom: Experiments With Heavy Water Futile. *Council Bluffs Nonpareil* (Council Bluffs, Iowa). 9 February 1946 p. 1. https://www.newspapers.com/article/the-daily-nonpareil/1957966/

MINDEN Germany, (AP)—German experiments with heavy water in attempts to split the atom during the war were unsatisfactory Prof. Otto Hahn, Germany's Nobel prize winning atomic scientist said Saturday.

'In itself heavy water is not an effective radio-active substance, but is used as an auxiliary for the splitting of uranium atoms,' he explained. 'We expected to need heavy water, but it was not so. Americans have proved that this can be done more simply and effectively by using carbon.'

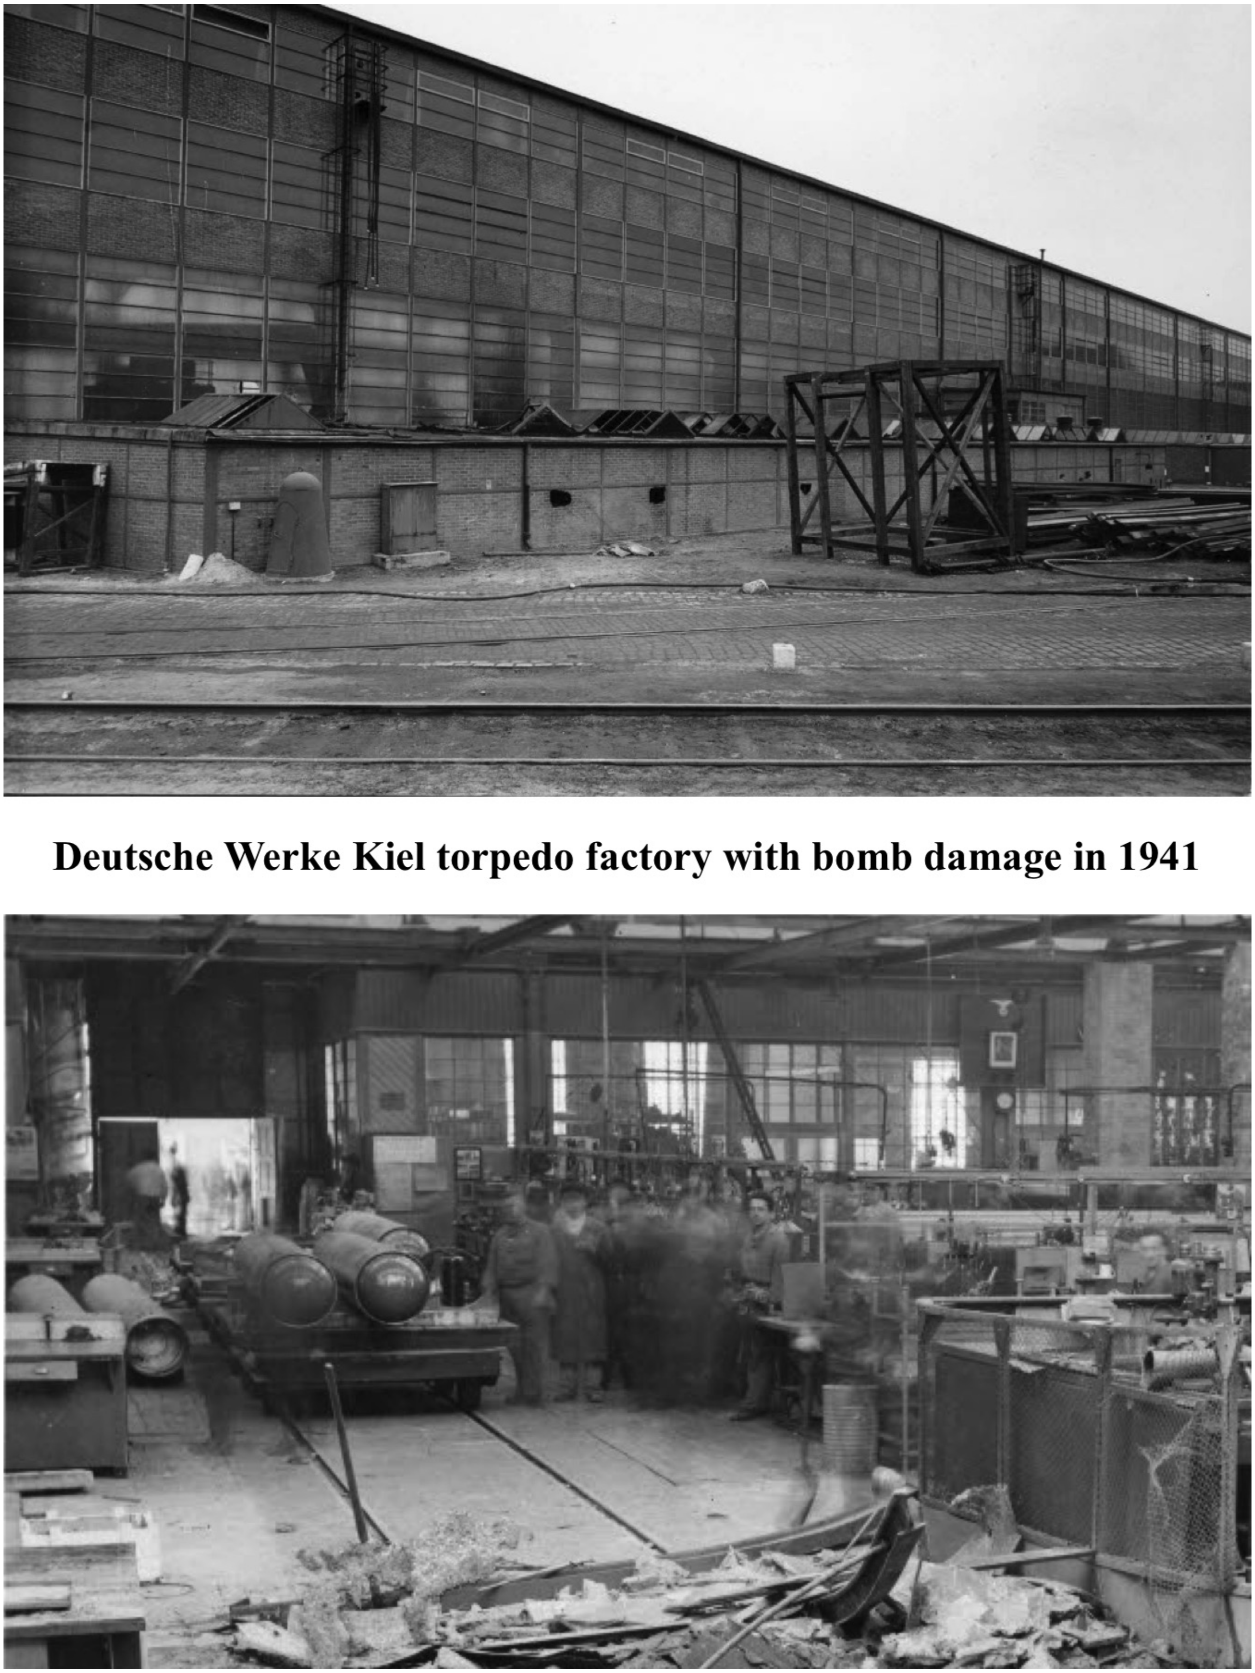
Heavy water plants were built by the Nazis in Norway for atomic bomb research work. British and Norwegian commandos in a highly successful raid blew them up.

(Heavy water has a specific gravity greater than ordinary water. Its hydrogen content is of atomic weight two, rather than atomic weight one).

Another atom scientist in the British occupation zone of Germany—Prof. Paul Harteck of the Kaiser Wilhelm institute of physics in Berlin—said that the light rays thrown out during the enormous explosion of an atomic bomb added greatly to the destructive force.

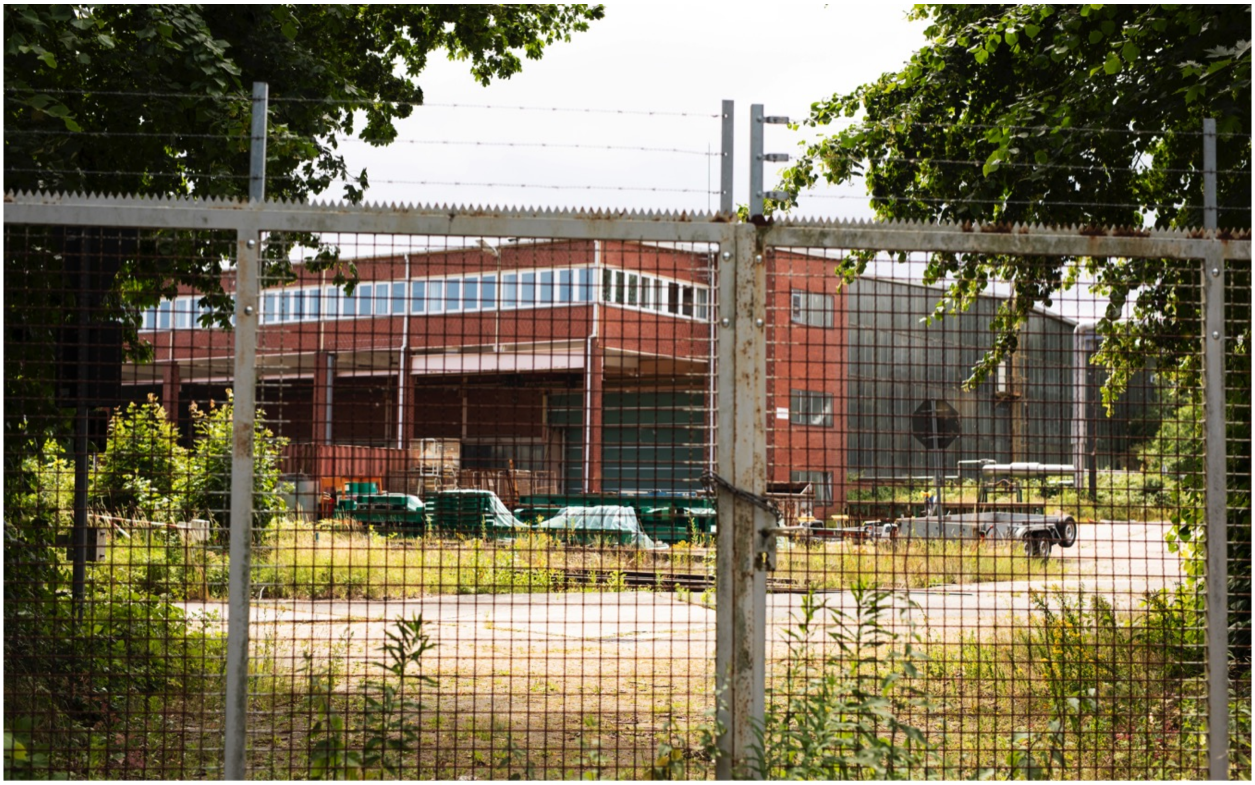
'The splitting of the atom causes a temperature of more than 10,000,000 degrees and aerial allure which destroy everything,' Harteck said.

This frees an amount of light which is beyond the visible spectrum. Only a few people know that the reflection of beams of light on solid bodies also exerts a mechanical pressure. This pressure is so small where our normal light is concerned that it is not noticed. The amount of light freed by an atomic bomb is so great it destroys walls.



Deutsche Werke Kiel torpedo factory with bomb damage in 1941

Figure D.500: The Deutsche Werke Kiel torpedo factory (shown here with bomb damage in 1941) was approximately four miles north of central Kiel, and is likely the location that Charles Chamberlain described.



Site of the former Deutsche Werke Kiel now.
The round concrete bunker was built during the war.

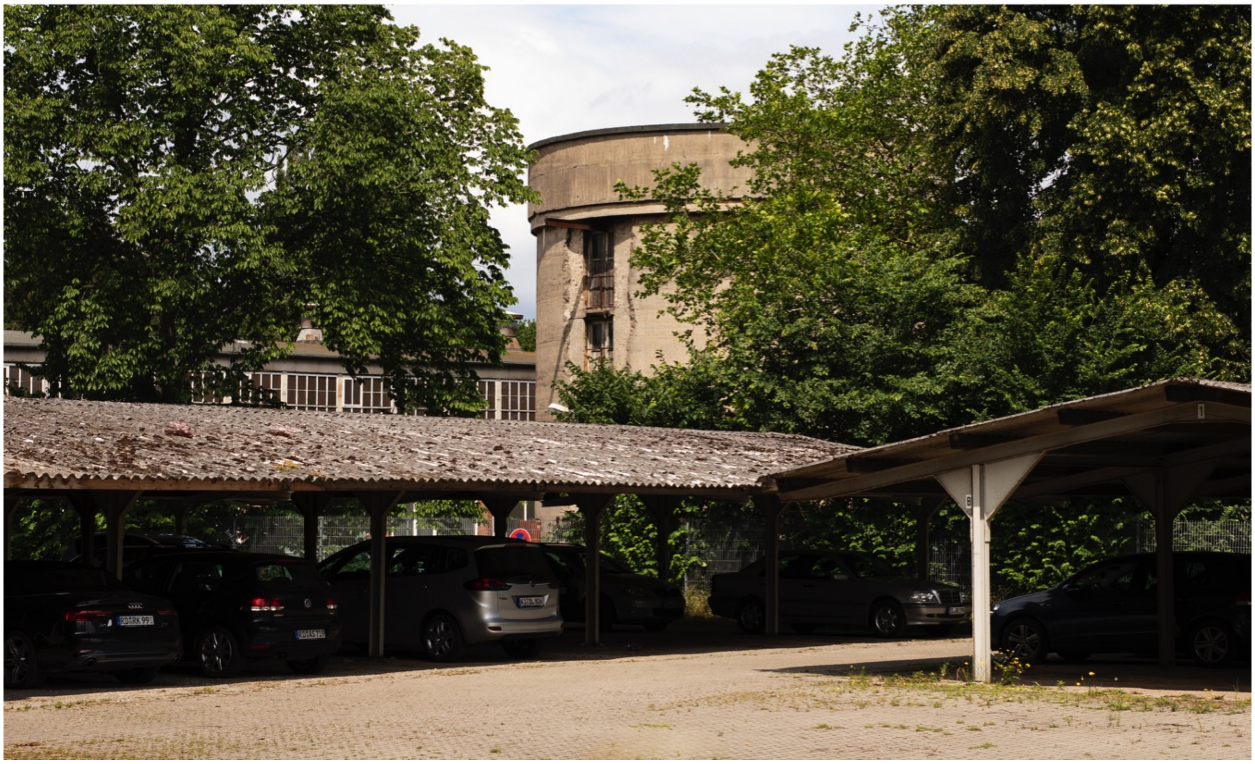


Figure D.501: Site of the former Deutsche Werke Kiel now. The round concrete bunker (lower photo) was built during the war. Other bunkers are known to have been built, but have been demolished or paved over.

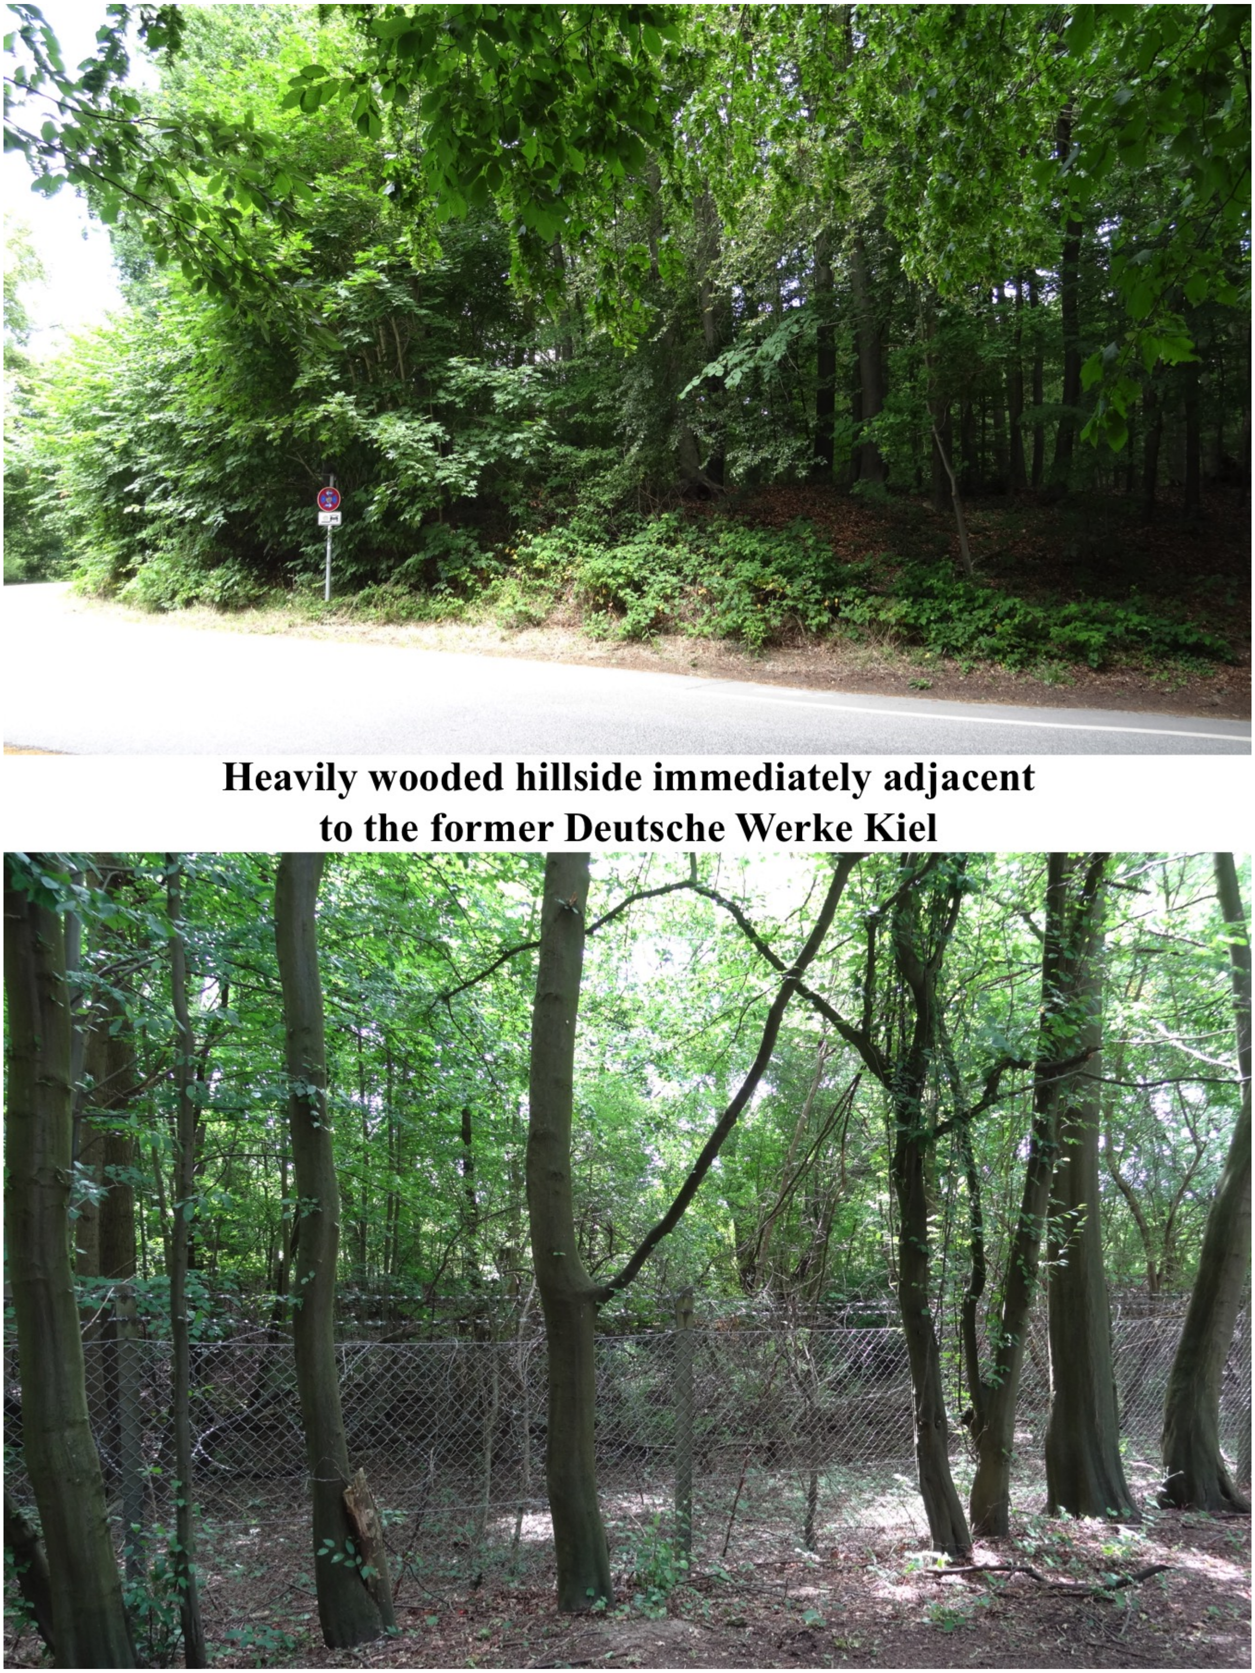

Heavily wooded hillside immediately adjacent
to the former Deutsche Werke Kiel

Figure D.502: There is a heavily wooded hillside immediately adjacent to the former Deutsche Werke Kiel, exactly as Charles Chamberlain described. Are the remains of the heavy water bunker in this area?

Shas.

23 February 1945

Subject: Status of Enemy Separation Projects.

MEMORANDUM to Major F. J. Smith from Dr. K. Cohen.

Centrifuges

Scientific leaders are P. Harteck now in Freiburg and H. Martin last reported in Kiel. Manufacturer of centrifuge is Anschutz, Kiel. Dr. Beyerle of this firm is probably responsible. Location of principal installations: Freiburg (Hinterzarten?) and Kiel. ~~General:~~ Progress: March 20, 1943, Martin at Heidelberg urged the construction of centrifuges which presumably were not yet authorized. ~~Progress:~~ Freiburg installation probably began construction about August 1943. By May 1944 there was an interesting installation. Kiel installation was completed but no tests made (according to Werner Kuhn) in July 1944. This machine reaches a peripheral velocity of 3 x 10^4 cm/sec. which is respectable. Main technical problem is said to be heat generated by this speed. This is really a minor problem and indicates lack of experience in centrifugation by Germans.

Conclusion: No installation larger than pilot plant.

Thermal Diffusion in Gases

Fleischmann reported negative results on experiments with 13 meter tubes at Berlin conference early in 1941. Expected separation was 2.-3 fold, none obtained.

Heavy Water Production

About the only enemy activity at all comparable in scale to ours. Harteck appears to be leading this work. Methods considered in 1941 meeting were electrolysis, chemical exchange with platinum catalysts, distillation of water and low temperature distillation of liquid hydrogen. 1942 conference goes over same questions. Former administration building of
Chemische Fabrik Griesheim-Elektron, Frankfurt am Main

Figure D.505: Former administration building of Chemische Fabrik Griesheim-Elektron, Frankfurt am Main. Griesheim-Elektron reportedly produced large quantities of heavy water during the war. See also pp. 3678–3680. The Griesheim plant appears to have been occupied and tightly controlled by the U.S. military for nearly a year and a half after the war. See for example https://de.wikipedia.org/wiki/Chemische_Fabrik_Griesheim-Elektron and sources cited therein.

12. Berlin and 13. Munich

Mark Walker. 1989. *German National Socialism and the Quest for Nuclear Power, 1939–1949.* Cambridge, UK: Cambridge University Press. p. 145:

Between the electrolysis unit at the Kaiser Wilhelm Institute for Physics and the planned Clusius-Linde plant, large-scale electrolysis was superfluous—something that Harteck had been arguing since 1940. On the other hand, Linde needed one and a half years before full operation could be expected. In late July of 1944 Allied air raids severely damaged the Linde plant in Munich.

G-105. Linde Ice Machine Company. 1941. *Process for Producing Heavy Hydrogen and/or Heavy Water.*

Ordinary hydrogen is cooled, liquified, and continuously rectified. Since HD has a lower vapor pressure than H_2 such an isotope separation is possible. The hydrogen is thus enriched 5%. Catalytic process to split H_2 and D_2. The resulting mixture of $H_2 + HD + D_2$ can be further rectified or it can be oxidized to $H_2O + HDO + D_2O$, and pure D can then be obtained by the usual electrolytic process. Special arrangement for cooling the hydrogen by boiling liquid nitrogen. Diagram showing how rectification can be continuous. Method for removal of impurities.

[See also G-261.]

Klaus and Ann M. Hentschel. 1996. *Physics and National Socialism: An Anthology of Primary Sources.* Basel: Birkhäuser. p. 151:

[I]n 1944 the Linde Company was destroyed in an air raid, partly because it was involved in the production of heavy water (deuterium) for the *Uranverein*. Cf. *75 Jahre Carl v. Linde Gesellschaft für Eismaschinen*, Frankfurt: Brönner, 1954, pp. 123–125, and Walker [1989]a, pp. 144f.

14. Sinigo-Merano and 15. Cotrone, Italy

Per F. Dahl. 1999. *Heavy Water and the Wartime Race for Nuclear Energy.* Philadelphia: Institute of Physics. p. 211:

The only other potential source of heavy water in occupied Europe appeared to be two Montecatini electrolysis plants in Italy—one near Merano and one at Cotrone, with a combined power consumption of 68000 kW, or half that of Vemork. Harteck thought it possible to use the Italian plants for an enrichment to around 1%, whereupon the material could be shipped to Germany for further processing at I G Farben's Leuna works [13-11]. Both Esau and Harteck had personally inspected the Merano plant during the winter 1942–1943, but Esau, for one, was not enthusiastic about the Italian option. [...] At any rate, a Merano-Leuna arrangement was still a fall-back solution, in case of further troubles in Norway.

16. Auschwitz

U.S. Embassy, Warsaw. 12 August 1947. Report No. R-107-47, MIS-390731. Subject: Plants producing heavy water. [NARA RG 319, Entry 85A, Box 2534, Folder 390731–390740]

1. It is believed that no plants designed specially for the production of heavy water exist in Poland. It is reliably reported that the Germans built one such plant near OSWIECIM (Auschwitz) but that it was destroyed or moved out by the SOVIETS in 1945.

[It was "reliably reported" that the Germans had built a heavy water production plant in Poland during the war, and that it was removed by the Soviets.

See p. 4452 for more information.]

17. Heavy water plant near the Schmiedeberg (now Kowary, Poland) uranium mine

[See Witkowski 2013, p. 224.]

18. Breslau/Wrocław

Siegfried Knappe and Ted Brusaw. 1992. *Soldat: Reflections of a German Soldier 1936–1949.* New York: Orion.

[pp. ix-x:] The amount of detail in this narrative is possible because Siegfried Knappe kept a diary from his midteens until he went into Russian captivity on May 2, 1945. Additionally, he smuggled many photographs of his war years from his mother's home in East Germany when he tricked the East Germans into allowing him to go to West Germany upon his release from Russian captivity in December 1949. During approximately 450 hours of interviews, we used these photographs to help trigger his memory as we covered every episode of his war years many times.

Siegfried also had General Weidling's account of the 56th Panzer Korps' part in the fighting from the Oder River to Berlin and the defense of Berlin, which Weidling wrote for the Russians immediately after surrendering. And when Siegfried was released from Russian captivity in December 1949, one of his first acts was to write his own account of the same period and of his Russian captivity as well. Finally, Siegfried had a day-by-day report of his artillery battery's participation in the invasion of France in May 1940, written by his battery commander.

A writer could hardly ask for a more thoroughly documented subject.

Ted Brusaw
Dayton, Ohio
September 1991

[pp. 265–268:] Hitler had declared Breslau a fortress city, which meant that it was to be defended to the last man, even if it was surrounded and totally isolated. The army corps staff in Breslau was the home unit staff for the area, which meant that it was a peacetime staff, and that was why Schörner had wanted officers with extensive combat experience to get the place ready for siege.

The fortress corps staff in Breslau was about seventy people. Because Breslau was the capital of Silesia and had been declared a fortress, the responsibility of the Army Korps Area VIII General Command staff was broader than that of a normal military staff. [...]

I took over the duties of operations officer on January 31. [...]

Schörner had been right: the place was a military mess. All the staff people were handicapped or old, and they had no idea how to fight or how to defend a big city. Defense lines had to be designated, ditches had to be dug, preparations of all kinds had to be made. Wounded coming in from the front had to be accommodated. A factory for making heavy water for atomic experiments had been abandoned east of Breslau, and we had to plan and conduct a counterattack to destroy it and keep its secrets from falling into the hands of the Russians. We were constantly occupied with issuing instructions to civil defense units, decreasing staff personnel, issuing ammunition and supplies, providing weapons, enforcing Schörner's order that no man able to fight was to leave Breslau, keeping refugees supplied and moving, finding engines for hospital trains, keeping utilities operating, preventing looting, preparing landing strips in the city in preparation for the siege—all in addition to normal staff functions like the daily military report to Schörner. [...]

Together with Generalmajor von Ahlfen and his staff, we got things into shape so that Schörner was finally satisfied. On about February 10, the Russian offensive across the Oder River began south of Breslau, near Grottkau, and in the northwest near Steinau. In front of the fortress itself, fairly insignificant combat activity continued at first, but our 609th Division soon became involved in heavy fighting and was pushed back almost to the southern suburbs of Breslau.

On February 11, the 7th Infantry Division, which had successfully completed the operation to retake and destroy the heavy-water plant at Dyhernfurth across the Oder River, sent their vehicles and baggage train into Breslau and pushed south through an enemy that was advancing toward Breslau from the west to form a new front in the area south of Kant. On February 12, two Soviet forces closed the ring around Breslau at Domslau. With that, Breslau had become a fortress under siege.

[Breslau (now Wrocław, Poland) was besieged by the Soviet army beginning in February 1945 but did not surrender until the end of the war. As operations officer for the Breslau-area military staff, in charge of directing and reporting the actions of the German military in that area, Knappe would have been extremely well informed about the topics he discussed. As his interviewer/coauthor Brusaw noted, Knappe's recollections were reviewed thoroughly and were supported by detailed documentation from that time period.

Knappe twice mentioned a heavy water plant in the Breslau area, first saying it was "east of Breslau" and then saying it was at Dyhernfurth (now Brzeg Dolny), which is northwest of Breslau. Perhaps he was referring to two different plants, but it sounds as if he meant the same plant. A heavy water plant would need a plentiful source of water (to find the relatively rare deuterium), so a heavy water plant in the Breslau area would almost certainly be located on the Oder river, which comes from the southeast of Breslau, runs through the city of Breslau, and then flows to the northwest of Breslau. Based on the path of the river, perhaps the most straightforward explanation is that Knappe meant to say the heavy water plant was just east of Dyhernfurth, not Breslau.

It is possible that what Knappe thought was a heavy water plant was actually the relatively well known I.G. Farben/Anorgana Dyhernfurth plant for producing tabun nerve agent. That plant was indeed abandoned yet later sanitized by German forces in a manner similar to what Knappe described.[13] However, there are a number of reasons to think that Knappe's references to a heavy water plant were correct:

- Knappe described the facility as a heavy water plant at least twice (perhaps more times in his interviews with Brusaw when they "covered every episode of his war years many times") and very specifically added that its heavy water was used "for atomic experiments." In his position in the German military, Knappe certainly would have known what chemical weapons were and would have understood the difference.
- There were other reports of heavy water plants in Poland, including a plant near the Schmiedeberg (now Kowary) uranium mine [Witkowski 2013, p. 224] and a plant that was part of or near the I.G. Farben Auschwitz complex (pp. 4069, 4452).
- Uranium gas centrifuges were being produced at a factory in Breslau (p. 4522).
- There were reports of other nuclear facilities in Silesia (pp. 4504–4510), fission reactors in Königsberg (pp. 3928–3933), and a fission bomb test in Poland (Section D.11).
- Multiple weapons plants were often built in close proximity, so locating a heavy water plant near the Dyhernfurth tabun plant (and just upstream of it to the east, to avoid tabun-related contaminants) would be consistent with that German practice. That would also explain why Hitler made defending the Breslau area such a high priority, and why the German military protected Breslau to the end of the war: it was a strategic location for producing both nuclear and chemical (and perhaps other) weapons of mass destruction.]

19. Weer, Austria

Ferdinand Cap. 23 November 1950. Gutachten [courtesy of Silke Fengler].

Über Einladung von Herrn Oberst GOUSSOT, Innsbruck, hatte ich die Möglichkeit, am 21.XI.50 die Schwere-Wasser-Gewinnungs-Versuchsanlage des Herrn Werd in Wehr [sic: Weer] bei Wattens in Tirol zu besichtigen. Das Prinzip der Anlage besteht in Folgendem: An schwerem Wasser angereichertes Wasser wird den drei (später neun) Zellen der Apparatur zugeführt. In jeder Zelle befindet sich ein Diaphragme, eine Kathode und eine Anode. (Spannung pro Zelle 3 Volt, Gesamtstrom 60 A) Als Elektrolyt dient verdünnt Natronlauge. Die durch die Elektrolyse freigesetzten Gase Wasserstoff und Sauerstoff werden an Paladiumoberflächen katalytisch verbrannt; das entstehende Wasser, das an schwerem Wasser ärmer ist als das in der jeweiligen Zelle elektrolysierte Wasser, wird in die vorhergehende Zelle geleitet; von der ersten Zelle wird es in die Vorkonzentrieranlage geleitet.

Das in jeder Zelle zurückbleibende an schwerem Wasser reichere Wasser wird in die nächstfolgende Zelle überdestilliert—ein einfaches Einleiten ist nicht möglich, da sonst die Konzentration des Elektrolyten stark steigen würde. In weit beim Destillationsprozess gewöhnliches Wasser und schweres Wasser gemeinsam übergehen oder ob hierbei eine kleine (der Apparaturanlage also rückläufige) Trennung eintritt, ist dem Unterzeichneten nicht bekannt und müsste aus Spezialabhandlungen geklärt werden. Sollte eine Verschlechterung der Trennwirksamkeit eintreten so wäre es immerhin wohl möglich durch einen anderen Prozess des überleitens diesen Verlust auszugleichen.

At the invitation of Colonel Colonel GOUSSOT, Innsbruck, I had the opportunity to visit Mr. Werd's heavy water extraction test facility in Wehr [sic: Weer] near Wattens in Tyrol on 21 November 1950. The principle of the plant consists in the following: Water enriched with heavy water is supplied to the three (later nine) cells of the apparatus. Each cell contains a diaphragm, a cathode and an anode. (Voltage per cell 3 volts, total current 60 A) Sodium hydroxide solution diluted serves as electrolyte. The gases hydrogen and oxygen released by the electrolysis are catalytically burned on palladium surfaces; the resulting water, which is poorer in heavy water than the water electrolysed in the respective cell, is led into the preceding cell; from the first cell it is led into the pre-concentration plant.

The water that remains in each cell and is richer in heavy water is distilled into the next cell–a simple discharge is not possible, as otherwise the concentration of the electrolyte would increase sharply. The undersigned does not know whether the distillation process involves the combined use of water and heavy water or whether this results in a small separation (i.e. a retrograde separation of the equipment). Should a deterioration of the separation efficiency occur, it would at least be possible to compensate this loss by another process of transfer.

Der Grundgedanke der Apparatur von Herrn W. ist physikalisch vollkommen einwandfrei. Ob jedoch auf dieser Basis eine Grossproduktion aufgebaut werden kann, wagt der Unterzeichnete nicht zu entscheiden; Entwicklungsarbeiten durchzuführen ist jedoch nicht anzuraten, da diesbezüglich sowohl in Deutschland und Norwegen, als auch in den USA ausgedehnte Untersuchungen bereits vorgenommen wurden. Die Frage nach dem Aufbau einer Grossproduktion kann daher nur nach genauem Studium der einschlägigen Literatur (etwa Monographie von Urey, AEC Reports, FIAT Reports etc.) beantwortet werden. Die von Herrn W. angegebenen Schätzungen über den Strombedarf (rund 1000 kWh für ein Gramm schweres Wasser von 96 % Reinheit) könnten an sich richtig sein, sind aber mit grösster Vorsicht aufzunehmen. Eine Überprüfung ist ohne spezieller Angaben über den Trennfaktor der Elektrolyse nicht möglich.

Jedenfalls müsste ein Vergleich der Wirksamkeit mit den Methoden der NORSK HYDRO, RJUKAN, Norwegen, angestellt werden; auch soll noch auf eine neue, hier noch nicht genügend bekannt gewordene amerikanische chemische Methode (Löslichkeitsmethode) hingewiesen werden, die allem Anschein noch möglicherweise eine grössere Ausbeute verspricht, also die Elektrolysenverfahren.

The basic idea of Mr. W.'s apparatus is physically perfect. However, the undersigned does not dare to decide whether a large-scale production can be built on this basis; however, it is not advisable to carry out development work, as extensive investigations have already been carried out in this respect in Germany and Norway, as well as in the USA. The question of setting up a large-scale production can therefore only be answered after a detailed study of the relevant literature (e.g. monograph by Urey, AEC Reports, FIAT Reports etc.). The estimates given by Mr. W. of the electricity requirement (about 1000 kWh for a gram of heavy water of 96 % purity) could be correct in themselves, but must be taken with the greatest caution. A check is not possible without special information about the separation factor of the electrolysis.

In any case, a comparison of the effectiveness with the methods of NORSK HYDRO, RJUKAN, Norway, would have to be made; also, a new American chemical method (solubility method), which has not yet become sufficiently known here, should be pointed out, which to all appearances still possibly promises a higher yield, i.e. the electrolysis methods.

[See also the interview with Ferdinand Cap on pp. 4076–4077. This heavy water plant in the Austrian Alps was apparently quite large and fully operational during the war. It was likely built by or at least for the SS.

This facility was apparently only discovered by outsiders in 1950. It does not seem to be mentioned in any other known documents. Can more information be located in any archives around the world?

If there is so little surviving historical record of this large heavy water production plant, what other wartime heavy water plants (or other nuclear-related facilities) may have existed yet remain unknown today?]

24.XI. 50

Doz Dr.F.Cap

Monsieur le Colonel GOUSSOT
Neues Landhaus Innsbruck

Mon Colonel,

J'ai l'honneur de vous transmettre ci-joint l'exposé que vous avez demandé. Le Professeur Schrödinger M-a chargé de dresser l'exposé - il regrette de ne pas pouvoir signer comme il né s' est pas occupé beaucoup des problèmes en question étant pure théoreticien.

Figure D.507: Ferdinand Cap. 23 November 1950. Gutachten [courtesy of Silke Fengler].

Rainer Karlsch. Interview with Ferdinand Cap. 5 February 2009 [courtesy of Rainer Karlsch].

Karlsch: Mich interessiert, wer diese Anlage gebaut hat. Sie erwähnten damals einen Herrn Werdt (W.). Er kann doch unmöglich allein eine solche Anlage Gebaut haben. Wer waren seine Auftraggeber? Natürlich ist es denkbar, dass die SS die Anlage im Zillertal in Auftrag gegeben hat. Gibt es dafür Belege?

Cap: Wer die Anlage gebaut hat, weiss ich nicht, glaube Norsk Hydro. Herr W. war nur Werksleiter und hat mich und Schroedinger geführt.

Karlsch: Prof. Oberkofler schreibt in seiner Studie "Ferdinand Cap und Otto Hittmair. Aus den Pionierjahren der Innsbrucker Theoretischen Physik", Innsbruck 2006, auf S. 27f.: "Auf dringliche Anforderung von Seiten der französischen Besatzungsmacht besichtigte Schrödinger in Begleitung von Cap im November 1950 die von der SS wie in Norwegen auch im Zillertal gebaute Anlage zur Gewinnung von Schwerem Wasser durch Elektrolyse." Mir ist nicht bekannt, dass die SS in Norwegen eine Schwerwasseranlage gebaut hat. Die dortigen Elektrolysezellen der Norsk Hydro (Anteilseigner war die IG Farbenindustrie AG) wurde nach den Entwürfen von Prof. Paul Harteck (Hamburg) und seiner Mitarbeiter 1942 erweitert und im August 1944 demontiert und ins Reichsgebiet geschafft. Mit dem Betrieb der Schwerwasseranlage in Norwegen hatte die SS meines Wissens nichts zu schaffen.

Cap: Harteck und WIRTZ sind mir bekannt. ICH HABE NIE BEHAUPTET DASS DIE SS DIE ANLAGE GEBAUT HAT.

Karlsch: Oder ist noch eine andere Anlage gemeint? Es gab ja nicht nur das Werk in Rjukan, sondern auch noch Anlagen in Saaheim und Nodotten, die sich aber ebenfalls in Regie der Hydro befanden.

Karlsch: I am interested in who built this plant. You mentioned a Mr. Werdt (W.) at that time. He couldn't have built such a plant on his own. Who were his clients? Of course it is conceivable that the SS commissioned the plant in the Zillertal. Is there any evidence of this?

Cap: I don't know who built the plant, Norsk Hydro I believe. Mr. W. was just a plant manager and led me and Schroedinger.

Karlsch: Prof. Oberkofler writes in his study "Ferdinand Cap and Otto Hittmair. From the pioneering years of Innsbruck's Theoretical Physics," Innsbruck 2006, on p. 27f: "On urgent request of the French occupying power Schrödinger, accompanied by Cap, visited in November 1950 the plant for the production of heavy water by electrolysis built by the SS in the Zillertal as in Norway." I do not know that the SS built a heavy water plant in Norway. The electrolysis cells of Norsk Hydro there (the shareholder was IG Farbenindustrie AG) were expanded in 1942 according to the designs of Prof. Paul Harteck (Hamburg) and his employees and dismantled in August 1944 and transported to the territory of the Reich. To my knowledge, the SS had nothing to do with the operation of the heavy water plant in Norway.

Cap: I know Harteck and WIRTZ. I NEVER CLAIMED SS BUILT THE PLANT.

Karlsch: Or is there another plant meant? There was not only the plant in Rjukan, but also plants in Saaheim and Nodotten, which were also directed by Hydro.

Cap: Nein, nur Zillertal mir bekannt.	Cap: No, I only know Zillertal.
[...]	[...]
Karlsch: Die Norsk Hydro scheidet als Bauherr oder Betreiber m.E. aus. Weder in den Unterlagen der Norsk, noch in den Erinnerungen ihrer leitenden Mitarbeiter und auch nicht in den Papieren der IG Farben, damals Hauptaktionär bei der Norsk, findet sich ein Hinweis darauf. Es bleibt also unklar, wer die Auftraggeber für die Anlage waren.	Karlsch: Norsk Hydro is no longer the owner or operator in my opinion. Neither in the documents of Norsk, nor in the memories of its leading employees, nor in the papers of IG Farben, then the main shareholder of Norsk, is there any indication of this. It therefore remains unclear who the contractors for the plant were.
Cap: Leider, offenbar. Ich wäre laut H. W. der Meinung gewesen NORSK HYDRO.	Cap: Unfortunately, apparently. I would have thought, according to Mr. W., NORSK HYDRO.
Karlsch: Können Sie sich daran erinnern, wo genau die Anlage stand?	Karlsch: Can you remember exactly where the plant was located?
Cap: Ziemlich ganz am Ende des Zillertales, nahe einem Gletscher.	Cap: Quite at the end of the Zillertal, near a glacier.
Karlsch: Welche Ausmaße hatten die Elektrolysezellen ungefähr?	Karlsch: What were the approximate dimensions of the electrolysis cells?
Cap: Hunderte Zellen, verschiedene Groesse, kleinere wie Waschbecken, mittlere wie Badewanne.	Cap: Hundreds of cells, different sizes, the smaller like a sink, the medium like a bathtub.
Karlsch: War Herr Werdt Ingenieur oder Physiker?	Karlsch: Was Mr. Werdt an engineer or a physicist?
Cap: Ich würde sagen H. Werdt war Gewerbeschultechniker. Sicher nicht Akademiker.	Cap: I would say Mr. Werdt was a vocational school technician. Certainly not an academic.
Karlsch: Stand er in Verbindung mit der Physiker-Gruppe des Physikalisch-Chemischen Instituts der Universität Innsbruck, die 1944 nach Wattens zur Firma Swarovsky verlegt wurde?	Karlsch: Did he stand in contact with the physicist group of the Physical-Chemical Institute of the University of Innsbruck, which was transferred to Swarovsky in Wattens in 1944?
Cap: Meinen Sie Frau Prof Erika Cremer, die im Krieg beim Berliner “URANVEREIN” war?	Cap: Do you mean Prof. Erika Cremer, who was in the Berlin “URANVEREIN” during the war?

21. Degussa plant, Rheinfelden, Austria, and
22. Austrian Chemical Works plant, Weissenstein, Austria

R. W. Kirkman. 28 January 1944. Subject: Carl William Tucker [NARA RG 77, Entry UD-22A, Box 171, Folder 32.7003-1 GERMANY: US Wartime Positive Int. (July 42–June 44)]

[...] 2. According to Major Furman, the substance of the conversation referred to was to the effect that Degussa was producing heavy water at two plants located at Rheinfelden and Weissenstein on the Drau River, Austria. Subject was said to have told Anderson that the chemist in charge of research being conducted on heavy water at Weissenstein was a Dr. Baum, now associated with F. W. Burke & Co., London, England.

23. Siemens and Halske plant in Lehesten

Monthly Intelligence Summary. February 1945. [NARA RG 77, Entry UD-22A, Box 168, Folder 202.3-1 LONDON OFFICE: Combined Intell Rpts.]

An OSS report states that possible manufacture of long range projectiles is being carried on in a semi-underground installation about 1.5 K.M. north of Lehesten in Germany. T A [Tube Alloy, nuclear] interest in the report arises from the fact that Siemens and Halske are said to be in charge of the plant, and a reference to the breaking down of water by electrolysis at this site. Aerial coverage has been requested.

28 January 1944

C/c destroyed 7/21/48

MEMORANDUM FOR THE OFFICER IN CHARGE.

Subject: Carl William Tucker.

1. By teletype letter-message dated 26 January 1944, Major Robert Furman of the Washington Liaison Office, requested this office to interview Carl William Tucker with respect to a conversation had by Subject with Ervin O. Anderson of the Department of Justice.

2. According to Major Furman, the substance of the conversation referred to was to the effect that Degussa was producing heavy water at two plants located at Rheinfelden and Weissenstein on the Drau River, Austria. Subject was said to have told Anderson that the chemist in charge of research being conducted on heavy water at Weissenstein was a Dr. Baum, now associated with F. W. Burke & Co., London, England.

3. On 27 January 1944, this officer interviewed Subject in an attempt to ascertain the source of Subject's knowledge and to obtain all facts possessed by Subject concerning the heavy water research before referred to. Subject was interviewed in his office in the du Pont Building, Wilmington, Delaware. The following is a result of that interview.

4. Subject stated that some time in the year 1926, Roessler and Hasslacher Chemical Company, Niagara Falls, New York, (now owned by and a part of du Pont), contemplated the installation of equipment for the production of hydrogen-peroxide. In order to effect proper installation of this equipment, Roessler and Hasslacher (hereinafter referred to as R & H) contracted with the Austrian Chemical Company at Weissenstein for the services of Dr. Baum, to supervise the installation of the equipment at Niagara Falls.

5. Dr. Baum came over to the United States some time during the year 1926 and supervised the installation of the hydrogen-peroxide equipment at R & H. It was Subject's recollection that Baum brought with him an assistant who acted more or less in the capacity of a foreman. The name of this assistant, Subject could not recall.

SECRET

SECRET

Subject: Carl William Tucker. 28 January 1944.

6. Subject was first employed by R & H in August of 1927 in a research capacity. Subsequently Subject became associated with Dr. Rykenboer in the production of hydrogen-peroxide. This was in the period of 1929-1931.

7. It was Subject's recollection that Dr. Baum had come back to the United States in 1928 or 29 and had visited the R & H plant at Niagara Falls.

8. In 1932 Subject visited Europe on a business trip and spent about two weeks at the Austrian Chemical Works plant at Weissenstein. During that visit, which was in the normal course of business, Subject again met Dr. Baum. At this time there was no discussion of research being conducted on heavy water.

9. In 1934 Dr. Baum again visited the United States and spent some time at the R & H plant. It was during this visit that Dr. Baum made mention of the fact that the Austrian Chemical Works was conducting research experiments with heavy water at its plant at Weissenstein. Subject believes that mention of this research by Dr. Baum arose during normal course of conversation between friendly acquaintances in the field of research. Subject considered the matter entirely normal in view of the relationship between the production of heavy water and hydrogen-peroxide. Subject recalls that Dr. Rykenboer was present at the time and possibly one or two other men associated with R & H were also present. Subject is uncertain as to the exact date of the incident but believes that it was about the time when announcement was made of Dr. Urey's experimentation with heavy water. Subject stated that he thought Baum had exhibited a picture of the equipment being used at Weissenstein and he believes that this picture may still be in the records of the plant at Niagara Falls. Subject also believes that there may be additional records of Dr. Baum's visit and the matters discussed at such times, in the plant records at Niagara Falls.

10. In 1935 Subject again visited Europe, in particular the Weissenstein plant. Subject stated that the purpose of this visit was the discussion of methods for the production of hydrogen-peroxide. At the time of this visit Subject did not see any of the equipment at Weissenstein which may have been used for the production of heavy water, nor was any reference to research on

SECRET

Subject: Carl William Tucker. 28 January 1944.

heavy water made by anyone concerned. Subject stated his belief to be that no assumption of any sort could be made as a result of Dr. Baum's silence - that is, Subject did not believe that it could be assumed that Baum's experimentation with heavy water had reached such a stage where he would not discuss it. Subject stated that it might just as well be assumed that Dr. Baum's silence concerning heavy water indicated that experimentation had ceased.

11. Subject stated that he thought that Dr. Baum may have returned again to this country in 1937 but he was not sure.

12. After the Anschluss, Dr. Baum managed to get out of Europe into England, where he became associated with F. W. Burke & Co. of London. Subject stated that he knew this to be so because of more or less personal correspondence between Dr. Baum and Dr. Rykenboer and between Dr. Baum and a Mr. Kutz, the Assistant General Manager of the Electrochemical Department of du Pont. Subject said that it was only natural for men engaged in the same fields of research to be familiar with each other's comings and goings.

13. During the course of the interview, Subject referred to conferences that had taken place between the Department of Justice and Subject. Upon questioning, Subject said that the purpose of these conferences was to give information which he possessed concerning location, size, production capacity, products produced, and sources of power of the various plants throughout Germany and its satellite States, with which Subject had become familiar during his European visits. Subject stated That Dr. Rykenboer had also given information of similar nature to the Department of Justice, as had Dr. L. M. White, Technical Director of the Electrochemical Department of du Pont. Subject said that correspondence along similar lines had passed between him and Mr. Ervin O. Anderson of the Department of Justice.

14. Subject said that he did not recall mentioning the heavy water plant at Weissenstein to Mr. Anderson. He believes that the reference may have been made by either Dr. Rykenboer or Dr. White. Subject is quite definite in stating that to his knowledge, no experiments on heavy water had been conducted at the Rheinfelden plant. So far as Subject knew, the Rheinfelden plant was owned by Degussa, whereas the Weissenstein plant was owned by the Austrian Chemical Works. Subject said, however, that Degussa may have had an interest in the Austrian Chemical Works. Subject stated that his recollection as to exact dates and names was not absolutely accurate. He offered to have Dr. Sterling Temple, Research Director of the plant

Subject: Carl William Tucker. 28 January 1944

at Niagara Falls, make a search of the records in an attempt to obtain more accurate information and any additional information that there might be. It was suggested to Subject that he not do this until he had heard further from this office. Subject was also cautioned against dissemination of information concerning the matter discussed.

Biography: Subject was born on 1 March, 1900, at Jamaica, Iowa, of American parents. He attended High School at Raton, New Mexico and later attended State University of Iowa from 1919-1924. He was graduated from the University with a B. S. degree in 1923, obtaining his M. S. in 1924. During 1924-1927, Subject attended Cornell University where he obtained a PHD in Physical Chemistry. Subject was employed by R & H in August, 1927, and remained with the company during its transition from R & H to the R & H Chemical Department of du Pont, and finally the Electrochemical Department of du Pont. Subject's position is that of Manager of Hydrogen-Peroxide Sales. Subject reads and speaks German and reads French.

Agent's Notes: Subject's manner of telling his story to this officer and Subject's attempts to fix dates and names and to fit together the various bits of information indicate that this was a matter which Subject had almost entirely forgotten about until the time of the interview. Subject may have mentioned the heavy water experimentation being conducted at Weissenstein in his talks with Mr. Anderson of the Department of Justice. Subject himself says that this was possible but he doubts it. At one point during the interview, Subject used substantially the following words: "Heavy water? I never thought of that." The reference is obvious. Every attempt was made, therefore, to minimize the importance of heavy water experimentation and every effort was made to conceal any possible interest the War Department might have in such experimentation. It is felt that Dr. Tucker is entirely loyal, discreet and cooperative.

Plans for Atomic and Chemical Research.

The following information comes from a reliable and well placed source in Czechoslovakia:

1. Work on the technical aspects of atomic research in Czechoslovakia probably will be assigned to the Association for Chemical and Foundry Industries. This organization, which is nationalized, is to become the policy-making and administrative center for the entire chemical industry.

2. Dr. Martinek, general manager of the Association, will become national administrator of the Czechoslovak chemical industry.

3. Plans are now under discussion to build a research and testing laboratory for explosives at Semin (M79), near Pardubice (Pardubitz). A chemical plant is already located there.

SUBJECT: Czech Plans for Atomic and Chemical Research.

TO: Colonel W. R. Shuler, Room 4181, New War Department Building, Washington, D. C.

1. In terms of actual progress within Czechoslovakia to date, the attached SSU Report (Number L-1308) should be interpreted almost exclusively as applying to the chemical industry. Systematic and large-scale work on atomic research exists only on paper, and even there in the most sketchy form.

2. It is definitely known that the Czechs are doing considerable work in the conventional field of new explosives. Laboratories are actively working on this subject, and proving grounds are in operation. One of our principal contacts in Prague, Jaroslav Heyrovsky, is now on a full-time basis with the Government laboratory.

3. All information to date shows that although this research is being pursued energetically, it is limited to the conventional and not the atomic field of explosives.

IN REPLY REFER TO EIDM T-1

SECRET

9 December 1943

TO: Brigadier General L. R. Groves
P. O. Box 2160
Washington, D. C.

1. Reference is made to your letter of 13 November requesting a report on any information which can be obtained at this location relative to the position of the enemy in the field of the project work. Following is a report of information obtained in casual conversations with Dr. H. C. Urey, Dr. M. Kilpatrick and Dr. R.H.Crist.

2. In a conversation on 5 December, Dr. Kilpatrick mentioned that he, in company with Dr. R. M. Burns of the Bell Telephone Laboratories, while on a recent hike with the Green Mountain Club, had met a Norwegian girl whose brother is, or was, employed in the Rjukan power plant in Norway. She had recently received uncensored mail from her brother in Norway, which stated that the #4 unit of the plant had been sabotaged, and that the Germans were rebuilding this unit as rapidly as possible. The girl stated also that she has in her possession photographs of this area, but that she does not want to give them up, since if this plant were bombed, it is likely that her family would be killed in the action. The plant evidently is situated in a narrow valley and the workers at the plant live in the immediate vicinity. Since this information was brought out in casual conversation, Dr. Kilpatrick did not write down the name of the girl. This can be obtained if necessary, through Dr. Burns and the Green Mountain Club. The girl is at present living in New York. Dr. Kilpatrick emphasized that his conversation was quite casual and that probably even Dr. Burns was not aware that he was trying to get information about the Rjukan plant.

3. In discussing the possible status of German work on the heavy water pile, it was stated that Dr. Urey saw the Norwegian scientist, L. Tronstad, in London about October or November of 1941. It was reported then that the Germans were taking heavy water from Norwegian sources, and it appears likely that they may have performed the critical experiments on cross-section some time before it was done in America. In this connection, Dr. C. P.Wigner of Chicago mentioned to Dr. Urey that he has had reports of heavy water plants now in production in Germany.

The interest of the SS in nuclear physics is obvious from a letter sent to Harteck as late as the 2nd of April, 1945. This letter is written by an SS Gruppenführer and Generalleutnant der Waffen SS. It comes from the Technical Bureau VIII FEP (probably research development patents) of the SS Führungshauptamt.

The text of the letter is to the effect that the General, whose name is illegible (probably starting with Sp) has ordered SS Standartenoberjunker H. Clasen to accelerate his work on the production of heavy water. For this reason, he asked Harteck, the leader of the heavy water group, to take him into his institute because this work could not easily be continued at the SS institute.

The original address in Berlin is blocked out of the letterhead. The new address is not given, but the mail address is Trebbin Krs. Teltow. [...]

P.S. 22 May 1945—I have today found out that the above mentioned General's name is Schwab.

Samuel A. Goudsmit. 15 June 1945. SUBJECT: Importance Attached to Harteck's Heavy Water Method. [NARA RG 77, Entry UD-22A, Box 166, Folder 32.22-1 GERMANY—Research—TA—(1943–June 1946)]. [See document photo on p. 4089.]

1. The enclosed letters came from the files of the Reichsforschungsrat. They are recent and again show the importance which the Germans placed upon the TA project.

2. First of all, there is a letter from Gerlach to Colonel Geist of the Speer Ministry. The letter is dated December 16, 1944. Here he tells about Harteck's new way of producing heavy water and that they expect to get three tons a year, the cost of the installation to be about 1,300,000 marks. The personnel consists of one engineer, three technicians and twelve laborers, and the price of the ultimate product is estimated at 20 pfennigs a gram. He requests Geist to give permission for proceeding with the production preparation at the highest priority A copy of this letter was sent by Dr. Graue, an administrator in the RFR, to the SS-Standartenführer Sievers, the SS representative in the RFR. An interesting passage is marked in the original of the covering letter. A rough translation is as follows:

> "With this (new procedure) we shall increase further the advantage which we have over the Americans. According to Professor Gerlach, the work in Germany has progressed so far that one may already count upon the possibility of practical results in the near future. You are aware that this would pave the way for a revolution in the whole field of technology and economy. Even if one disregards the possibility of an eventual war application, the support of this work is, nevertheless, absolutely essential."

3. Sievers, in turn, sent a copy of Gerlach's letter to Dr. Ing. Kammler (who was a Lt. General of the Waffen-SS in charge of armaments). In this letter, he literally copied the marked passage of Graue's letter and proposed that the work be done in a cave near Helmstedt because there was slave labor there already.

B. Lithium

[Lithium was used for processing ceramics, glass, and metals, but it would also have been extremely useful for producing tritium, neutrons, and/or fusion reactions. The following documents demonstrate large-scale production of lithium, as well as shipment of a large amount of lithium to Japan (along with other nuclear-related materials).

For documentation about wartime German separation of lithium isotopes, for which the only significant applications would be nuclear-related, see p. 4344.]

FIAT 295. *Lithium Extraction and Uses.* p. 9.

[...] Metallgesellschaft produced in 1942:

11637	kilograms	Lithium	from Lithium Mica
1702	”	”	Amblygonite in form of

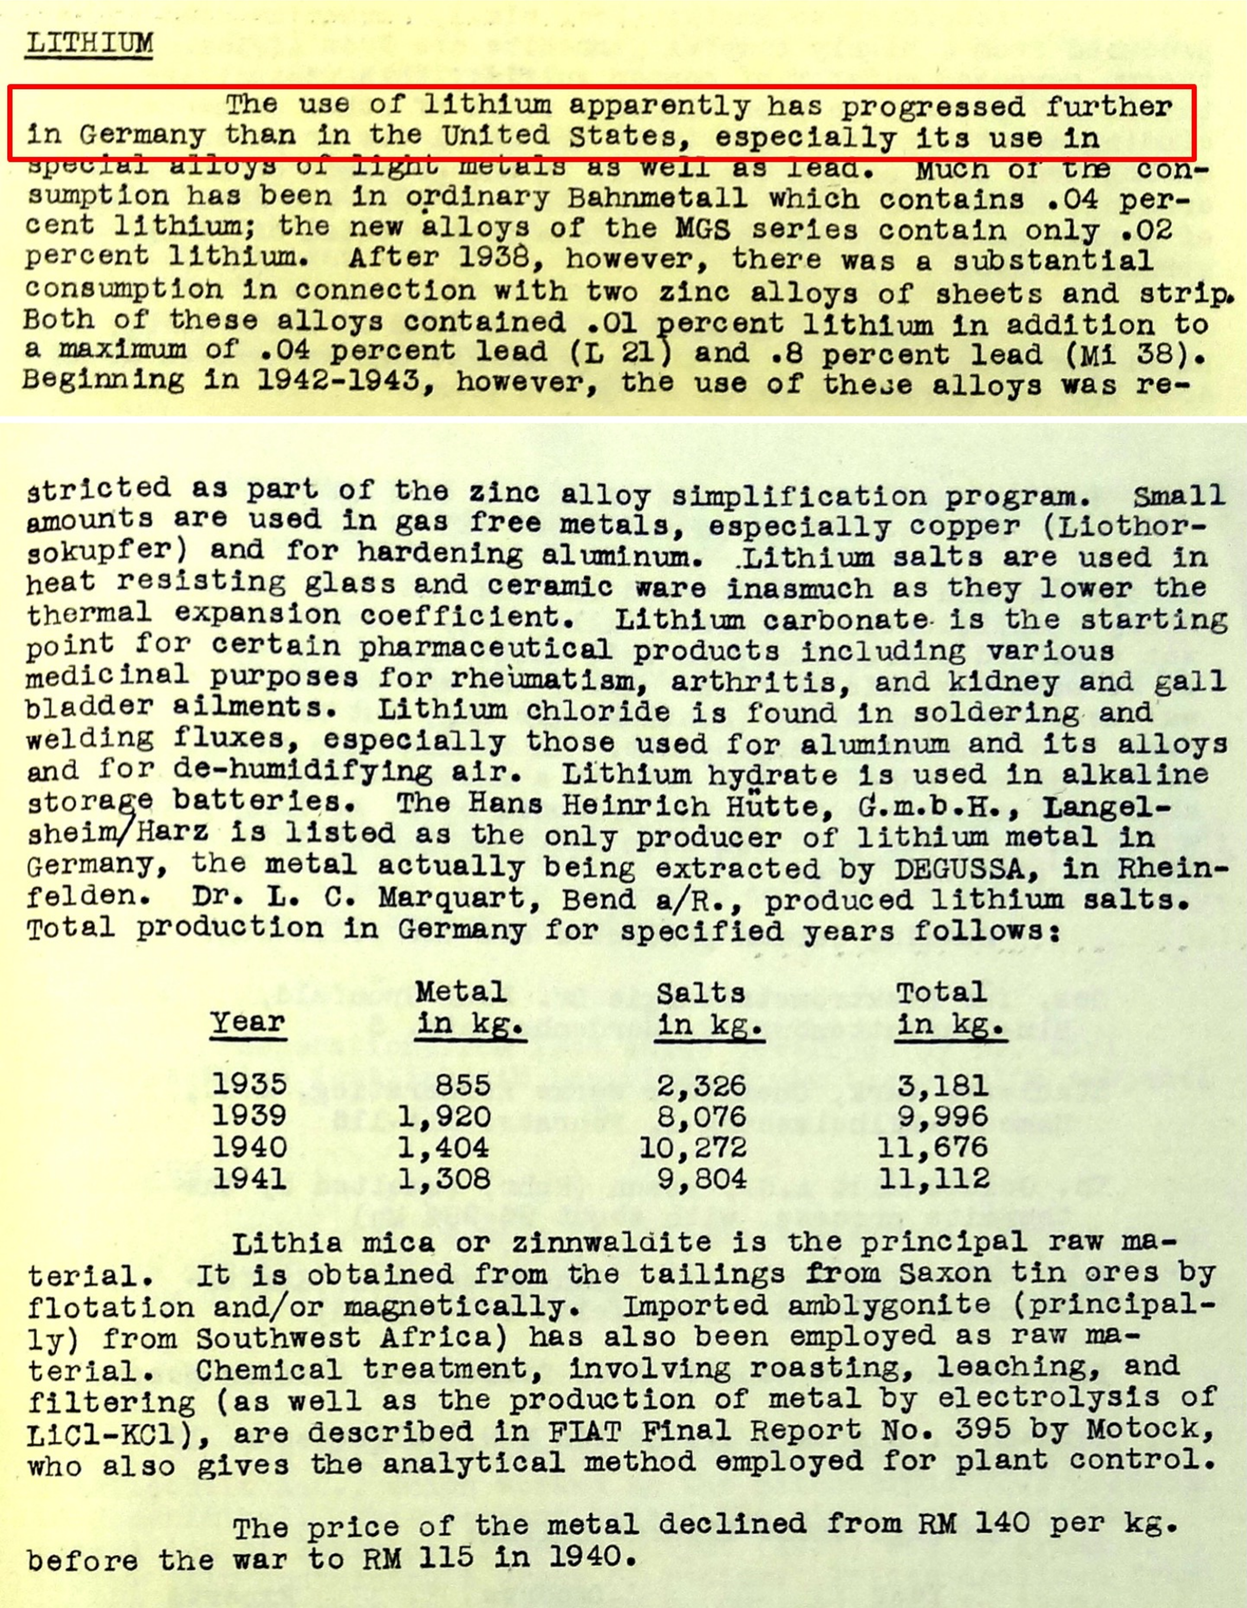
FIAT 750. *Rare and Minor Metals*, pp. 8-9



LITHIUM

The use of lithium apparently has progressed further in Germany than in the United States, especially its use in special alloys of light metals as well as lead. Much of the consumption has been in ordinary Bahnmetall which contains .04 percent lithium; the new alloys of the MGS series contain only .02 percent lithium. After 1938, however, there was a substantial consumption in connection with two zinc alloys of sheets and strip. Both of these alloys contained .01 percent lithium in addition to a maximum of .04 percent lead (L 21) and .8 percent lead (Mi 38). Beginning in 1942-1943, however, the use of these alloys was restricted as part of the zinc alloy simplification program. Small amounts are used in gas free metals, especially copper (Liothorsokupfer) and for hardening aluminum. Lithium salts are used in heat resisting glass and ceramic ware inasmuch as they lower the thermal expansion coefficient. Lithium carbonate is the starting point for certain pharmaceutical products including various medicinal purposes for rheumatism, arthritis, and kidney and gall bladder ailments. Lithium chloride is found in soldering and welding fluxes, especially those used for aluminum and its alloys and for de-humidifying air. Lithium hydrate is used in alkaline storage batteries. The Hans Heinrich Hütte, G.m.b.H., Langelsheim/Harz is listed as the only producer of lithium metal in Germany, the metal actually being extracted by DEGUSSA, in Rheinfelden. Dr. L. C. Marquart, Bend a/R., produced lithium salts. Total production in Germany for specified years follows:

Year	Metal in kg.	Salts in kg.	Total in kg.
1935	855	2,326	3,181
1939	1,920	8,076	9,996
1940	1,404	10,272	11,676
1941	1,308	9,804	11,112

Lithia mica or zinnwaldite is the principal raw material. It is obtained from the tailings from Saxon tin ores by flotation and/or magnetically. Imported amblygonite (principally) from Southwest Africa) has also been employed as raw material. Chemical treatment, involving roasting, leaching, and filtering (as well as the production of metal by electrolysis of LiCl-KCl), are described in FIAT Final Report No. 395 by Motock, who also gives the analytical method employed for plant control.

The price of the metal declined from RM 140 per kg. before the war to RM 115 in 1940.

Tokyo to Berlin ULTRA message 1443. 16 January 1945. [**Published in Henshall 2000, p. 57. What is the archival source of this document???**]

NAVAL SECTION
JNA 20 C/S 114/1/2/3
TOO 161920 January 1945
From: TOKYO
Action: BERLIN

ULTRA/ZIP/SJA/1443
MEW/535

Action: BWG [Chief Technical Superintendent].
From: CJR [Naval Technical Directorate].

Your secret telegram No. 848 [SJA/1358: enquires what cargo is to be shipped in submarines proceeding to the Far East].

It is desired to obtain the following material urgently by means of the German transport submarines proceeding to Japan.

2. For Department No. 3: [This line is typed differently than the rest, and there is some blank space here. Was information deleted here, and if so by whom?]

1) Diamond dies (diameter between 0.02 and 0.08 mm., as large a quantity as possible of all kinds).

2) Metallic zirconium (500 kg of a standard of 99.5 per cent or over).

3) Metallic lithium, 500 kg.

4) Neon gas (as much as possible).

5) Insulating material for ultra high frequencies, 10 kg of each kind.

6) 2,000 or more [HASPEKERNE, ? clamp cores].

[Clamp cores/nuclear, or nuclear/core clamps?]

3. For Department No. 5:

1) As many BOSCH fuel pumps models 10 and 6 as possible.

2) 1 polarizing microscope.

3) 10 cam shaft grinders.

4) 10 MAAG gear wheel grinders.

[Were there other related messages? Since zirconium and lithium seem like materials for nuclear work, are the other materials for "Department No. 3" also related to nuclear work? What exactly were the "HASPEKERNE" [Henshall 2000, pp. 56–58]?]

For more information on wartime lithium production and applications, see:

C. Beryllium

[Beryllium was used for producing certain metal alloys, but it also could have been quite useful as a neutron reflector and multiplier in a fission reactor, electronuclear breeding system, or fission bomb. The following documents illustrate that wartime production of beryllium was sophisticated and on a large scale.]

John E. Vance to Francis J. Smith. 17 July 1945. [NARA RG 77, Entry UD-22A, Box 163, Folder Australia]

1. Major Kelley stated that Madison Square Area had been called upon to furnish increased quantities of beryllium metal. The single source of beryllium metal at this time is the Brush Beryllium Company of Cleveland, Ohio, whose facilities are to be enlarged. However, to assist in meeting the requirements, Major Kelley suggested that it would be extremely valuable if it were possible to acquire beryllium metal discovered in Germany.

2. To be useful to use, the metal should be massive, i.e., should be in pieces rather than in flakes and should contain more than 90% beryllium; it would probably not be advisable to place other specifications on the metal.

H. S. Lowenhaupt to Francis J. Smith. 19 July 1945. [NARA RG 77, Entry UD-22A, Box 163, Folder Australia]

A cable to Major F. J. Smith, 17 May states that considerable beryllium was found in Germany by the AT Group. Whereabouts of this metal is not known at present.

A bill from the files (from Deutsche Gold und Silber Scheideanstalt Vormals Roessler, Degussa, Frankfort am Main, 7 May 1943 to the Heereswaffenamt, Berlin) is for 100 plates made of beryllium or 27.848 kg. at 140.20 marks per kg.

I suggest this firm be contacted by our people to see if they can still supply metallic beryllium, either through purchase, or as plunder.

[See document photos on p. 4097. The U.S. nuclear weapons program needed more beryllium than was being produced in the United States. Postwar U.S. investigators discovered that highly suitable beryllium had been made in large quantities in Germany—and had been shipped to Erich Schumann's Army Ordnance Office (Heereswaffenamt) during the war. The investigators also discovered that "considerable" additional quantities of beryllium had been produced and had disappeared into even more mysterious projects: "Whereabouts of this metal is not known at present."]

Office Memorandum • UNITED STATES GOVERNMENT

TO :Major F.J. Smith DATE:19 July 1945

FROM :H.S. Lowenhaupt

SUBJECT:Beryllium, re Memorandum to Major F.J. Smith from Major J.E. Vance, 17 July 1945

A cable to Major F.J. Smith, 17 May states that considerable beryllium was found in Germany by the AT Group. Whereabouts of this metal is not known at present.

A bill from the files (from Deutsche Gold und Silber Scheideanstalt Vormals Roessler, Degussa, Frankfort am Main, 7 May 1943 to the Heereswaffenamt, Berlin) is for 100 plates made of beryllium or 27.848 kg. at 140.20 marks per kg.

I suggest this firm be contacted by our people to see if they can still supply metalic beryllium, either through purchase, or as plunder.

Mineral trade notes no. 429, 3 July 1945, American Embassy, Rio de Janeiro, Brazil states that at present 800 tons of beryl, the best source of beryllium, is stocked in Brazil awaiting the untangling of international price difficulties. If the ore rather than the pure metal should be desired by Major Kelley, either now or in the future, Brazil could become an important supplier.

SURVEY OF FOREIGN EXPERTS
11 West 42nd Street
New York City

#N 7317 March 18, 1944

COUNTRY: GERMANY

SUBJECT: Austrian, 49, until 1938 representative of various firms in Austria, among them Heraeus Vacuum Schmelze in Hanau. He left Austria in April 1939 and arrived in the United States fron England in March 1940. Subject speaks English and German, and seems competent, reliable, and cooperative. He was interviewed in connection with an inquiry on

HERAEUS VACUUM SCHMELZE IN HANAU (as of 1938)

Contents: ECONOMIC IMPORTANCE; EQUIPMENT; EMPLOYMENT; CONSTRUCTION AND LAYOUT OF BUILDINGS; POTENTIAL SOURCE OF RAW MATERIAL.

RECEIVED MAR 25 1944

--o--

Economic Importance

The Heraeus Vacuum Schmelze manufactured nickel, chrome-nickel, berylium and aluminum-iron alloys, and vacuum molten iron and bimetal products.

Nickel and chrome-nickel alloys produced in the form of wires and bands, were supplied to electrical firms, to steel works which used them for steel hardening cases and for pyrometers for blast furnaces, and to the enameling industry. Its only important competitor in this field was the Krupp Works.

Berylium alloys, in which Heraeus Vacuum Schmelze had a monopoly, were supplied to the motor industry for valve springs, to the radio industry for contacts operating by elastic touch, and to manufacturers of special tools for explosive plants. They were used for the latter purpose because in addition to their toughness and enduring elasticity, they made no sparks when coming in physical contact with other hard objects.

#N 7317 March 18, 1944

Vacuum molten iron, in which this firm also had a monopoly, was used for electrodes for neon tubes, and because of its electric properties was also used for transformer lamelas.

Aluminum-iron wires were used for purposes similar to chrome-nickel wires. They were used most often when resistance to higher temperatures was needed, as aluminum-iron stood up under a temparature of 1300° cg., while chrome-nickel was only good up to 1200° cg. The disadvantage of aluminum-iron wire was its brittleness.

Special bimetal products were also rolled in this plant. Nickel and iron, for example, were combined to make temperature control devices for which two metals with different expansion coefficients were needed.

Equipment

The plant was equipped with special electric furnaces, with vacuum devices to extract the gases from the molten metal, and rolling and drawing mills. The furnaces and the rolling and drawing equipment were highly complicated and would be very difficult to replace if destroyed, not only from a technical point of view, but also because of scarcity of materials, such as special metals, used in their construction.

In Subject's opinion it would have been comparatively simple to transfer the entire plant from Hanau to a less exposed location, but he had never heard that this was planned or had been done.

Employment

The plant employed 1000 workers.

Construction and Layout of Buildings

The plant consisted of two or three rows of brick sheds with slate roofs.

#N 7317 March 18, 1944

Potential Source of Raw Material

Some time ago a berylium deposit was discovered in the Austrian coal mining district of Koeflach, about 30 km west of Graz by air. Test extractions were made, but commercial production had not been started up to the time of Subject's departure. As most of the berylium previously had been imported from overseas, it is possible that these deposits are now being exploited.

[Unless otherwise noted, text for G-series captured German nuclear reports cited here consists of the English-language abstracts prepared by American scientists who studied the German reports.]

G-35. Wilhelm Hanle. *Investigation of Cadmium Content of Carbon.* 1940.

Spectroscopic tests of charcoal prepared from sugar showed Cd content of about 10^{-7}, certainly less than 3×10^{-7}.

[See document photos on p. 4106.]

G-85. Wilhelm Hanle. *The Determination of Boron and Cadmium in Carbon.* 1941.

Method involves making spectroscopic analysis of C and comparing with C prepared from sugar to which a definite amount of boron nitride has been added. This is better than the usual boric acid because the vaporization of boron nitride compares more closely with that of boron carbide (the usual form of B in C) than does the more easily vaporized boric acid.

Cd content of sugar carbon about 10^{-7}, certainly less than 3×10^{-7}.

Boron content:

Sugar carbon	10^{-6}
Acheson graphite	10^{-4}
Beechwood carbon	10^{-5}
Arc lamp carbon, incandescent	10^{-4}

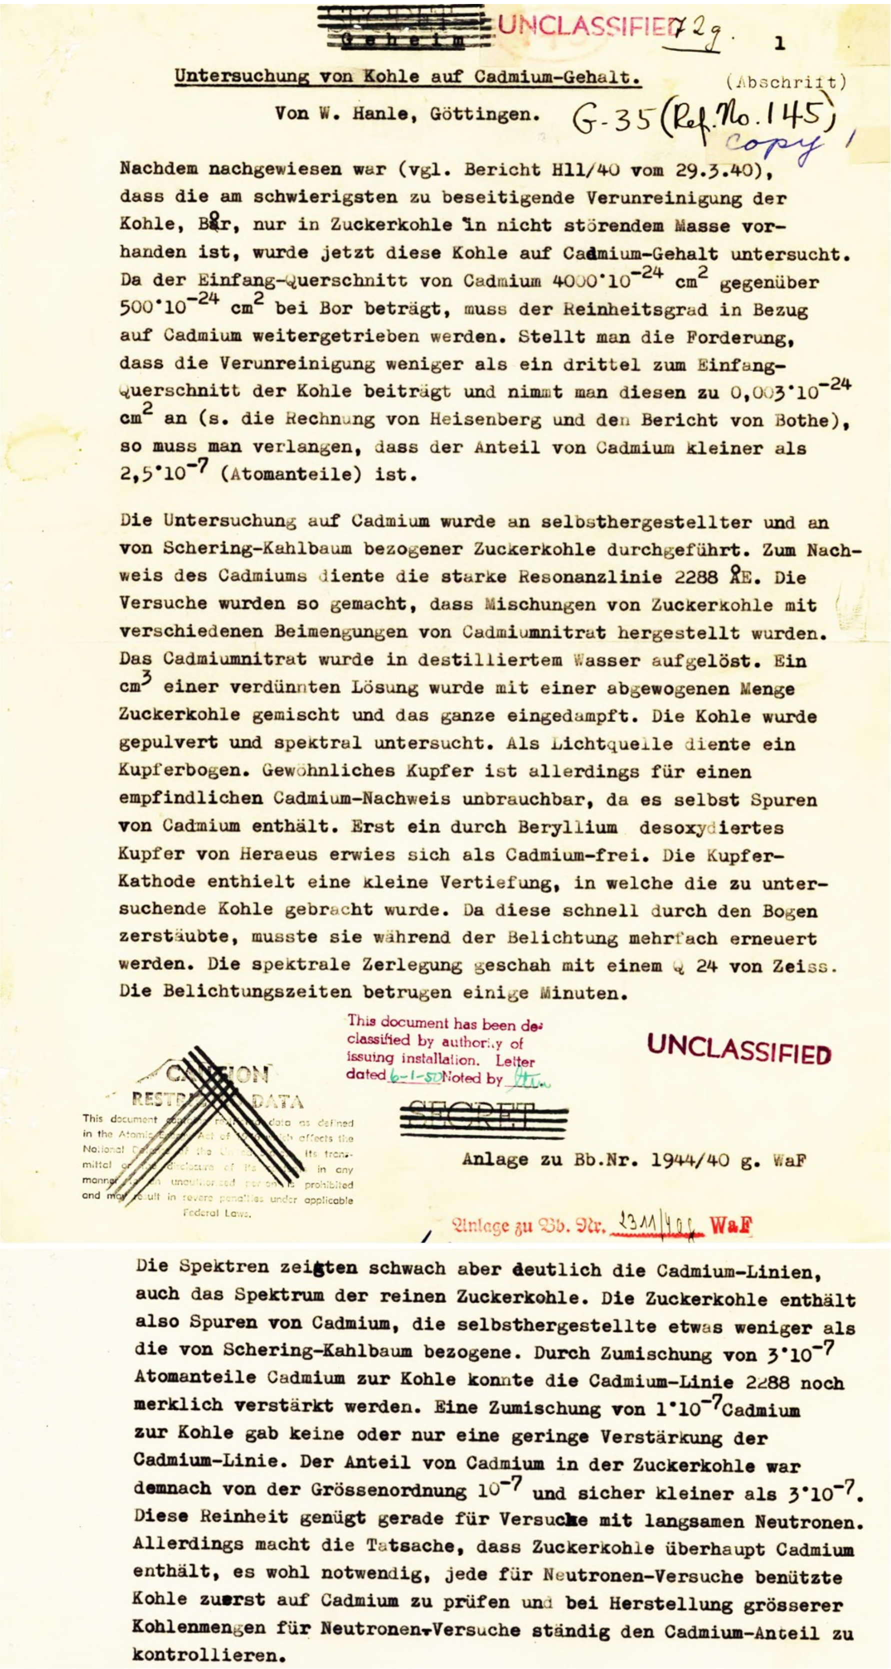
Siemens electrographite used by Bothe for his pile had a boron content between 10^{-5} and 2×10^{-6} atomic parts. The cadmium content was less than 3×10^{-7}.

[See document photos on p. 4107.]

G-153. Wilhelm Hanle. *Spectroscopic Analysis of Carbon, Aluminum, and Beryllium.* 1942.

Graphite used by Bothe, Al used by Döpel and Heisenberg, and Be oxide used by Haxel and Volz submitted for test. B content of graphite lies between 0.6 and 0.8×10^{-5} atoms of B per atom of C. Cd content of Al is less than 10^{-5} mole per mole. B content of Al is also less than 10^{-5} mole per mole. Cd content of Be oxide is less than 10^{-5} mole per mole. B content of Be oxide is less than 10^{-3} and more than 10^{-5} mole per mole.

[See document photos on pp. 4108–4109.]



~~SECRET~~
~~Geheim~~ UNCLASSIFIED 72g. 1

Untersuchung von Kohle auf Cadmium-Gehalt. (Abschrift)

Von W. Hanle, Göttingen. G-35 (Ref. No. 145) copy 1

Nachdem nachgewiesen war (vgl. Bericht H11/40 vom 29.3.40), dass die am schwierigsten zu beseitigende Verunreinigung der Kohle, Bor, nur in Zuckerkohle in nicht störendem Masse vorhanden ist, wurde jetzt diese Kohle auf Cadmium-Gehalt untersucht. Da der Einfang-Querschnitt von Cadmium $4000 \cdot 10^{-24}$ cm^2 gegenüber $500 \cdot 10^{-24}$ cm^2 bei Bor beträgt, muss der Reinheitsgrad in Bezug auf Cadmium weitergetrieben werden. Stellt man die Forderung, dass die Verunreinigung weniger als ein drittel zum Einfang-Querschnitt der Kohle beiträgt und nimmt man diesen zu $0{,}003 \cdot 10^{-24}$ cm^2 an (s. die Rechnung von Heisenberg und den Bericht von Bothe), so muss man verlangen, dass der Anteil von Cadmium kleiner als $2{,}5 \cdot 10^{-7}$ (Atomanteile) ist.

Die Untersuchung auf Cadmium wurde an selbsthergestellter und an von Schering-Kahlbaum bezogener Zuckerkohle durchgeführt. Zum Nachweis des Cadmiums diente die starke Resonanzlinie 2288 ÅE. Die Versuche wurden so gemacht, dass Mischungen von Zuckerkohle mit verschiedenen Beimengungen von Cadmiumnitrat hergestellt wurden. Das Cadmiumnitrat wurde in destilliertem Wasser aufgelöst. Ein cm^3 einer verdünnten Lösung wurde mit einer abgewogenen Menge Zuckerkohle gemischt und das ganze eingedampft. Die Kohle wurde gepulvert und spektral untersucht. Als Lichtquelle diente ein Kupferbogen. Gewöhnliches Kupfer ist allerdings für einen empfindlichen Cadmium-Nachweis unbrauchbar, da es selbst Spuren von Cadmium enthält. Erst ein durch Beryllium desoxydiertes Kupfer von Heraeus erwies sich als Cadmium-frei. Die Kupfer-Kathode enthielt eine kleine Vertiefung, in welche die zu untersuchende Kohle gebracht wurde. Da diese schnell durch den Bogen zerstäubte, musste sie während der Belichtung mehrfach erneuert werden. Die spektrale Zerlegung geschah mit einem Q 24 von Zeiss. Die Belichtungszeiten betrugen einige Minuten.

~~SECRET~~

Anlage zu Bb.Nr. 1944/40 g. WaF

Anlage zu Bb. Nr. 2311/40 g. WaF

Die Spektren zeigten schwach aber deutlich die Cadmium-Linien, auch das Spektrum der reinen Zuckerkohle. Die Zuckerkohle enthält also Spuren von Cadmium, die selbsthergestellte etwas weniger als die von Schering-Kahlbaum bezogene. Durch Zumischung von $3 \cdot 10^{-7}$ Atomanteile Cadmium zur Kohle konnte die Cadmium-Linie 2288 noch merklich verstärkt werden. Eine Zumischung von $1 \cdot 10^{-7}$ Cadmium zur Kohle gab keine oder nur eine geringe Verstärkung der Cadmium-Linie. Der Anteil von Cadmium in der Zuckerkohle war demnach von der Grössenordnung 10^{-7} und sicher kleiner als $3 \cdot 10^{-7}$. Diese Reinheit genügt gerade für Versuche mit langsamen Neutronen. Allerdings macht die Tatsache, dass Zuckerkohle überhaupt Cadmium enthält, es wohl notwendig, jede für Neutronen-Versuche benützte Kohle zuerst auf Cadmium zu prüfen und bei Herstellung grösserer Kohlenmengen für Neutronen-Versuche ständig den Cadmium-Anteil zu kontrollieren.

Über den Nachweis von Bor und Cadmium in Kohle

Wenn bei der Uran-Maschine Kohle als Bremssubstanz benutzt wird, muß darauf geachtet werden, daß der Gehalt an Bor und Cadmium wegen ihres großen Einfangquerschnittes für langsame Neutronen genügend klein ist. Die Mehrzahl der Kohlen enthält Bor in beträchtlicher Menge, wie aus der Tabelle hervorgeht. Die angegebenen Werte wurden spektroskopisch bestimmt. Nur die aus Zucker hergestellten Kohlen sind praktisch borfrei. Der Gehalt der anderen Kohlen wurde durch Vergleich mit Zuckerkohle, der eine bestimmte Menge Borsäure zugemischt war, bestimmt. Bei dieser Methode ist es allerdings möglich, daß man nur eine untere Grenze erhält. Denn im Graphit z.B. ist das Bor sicher als Borkarbid enthalten und schwer verdampfbar, während das Bor aus der mit Borsäure getränkten Zuckerkohle leichter verdampft. Die Versuche wurden so gemacht, daß fein gepulverte Kohle in die Bohrung einer Kupferelektrode gefüllt wurde. Im Lichtbogen spritzte ein Teil der Kohle heraus, und es ist möglich, daß dabei das Bor aus der Borsäure vollständig, aus dem Borkarbid jedoch nur teilweise verdampft. Tatsächlich hat Goldschmidt früher in Kohleaschen etwas größere Boranteile gefunden. Unsere Methode hat den Vorteil, daß man die Kohle nicht veraschen muß. Sie lieferte zunächst den Beweis, daß die gewöhnliche Kohle wegen des großen Boranteiles sicher unbrauchbar ist, die Zuckerkohlen jedoch weitgehend borfrei sind. Neuerdings wurde nun auch der von Herrn Bothe bei seiner Bestimmung der Neutronenabsorption in Kohle benutzte Elektrographit von Siemens untersucht. Der Borgehalt konnte vorläufig nur in zwei Grenzen eingeschlossen werden: Er ist kleiner als 10^{-5} und sicher größer als 2.10^{-6}. Die Frage ist nun, kann ein Teil der von Bothe gemessenen Neutronenabsorption durch den Borgehalt verursacht sein? Bothe hat einen Neutronenabsorptionsquerschnitt von $0,0075.10^{-24}$ cm^2 gemessen, während Heisenberg $0,003.10^{-24}$ cm^2 berechnet hat. Nehmen wir einmal an, daß die ganze Differenz von $0,004.10^{24}$cm^2 von der Absorption im Bor herrührt. Dann müßte der Boranteil 9.10^{-6} gewesen sein. Die vorläufigen Versuche geben kleiner als 10.10^{-6} und größer als 2.10^{-6}. Also ist immerhin möglich, daß die große Neutronenabsorption im Siemens-Elektrographit von der Borverunreinigung herrührt. Selbstverständlich wird man jetzt, wo es auf den genauen Boranteil ankommt, die Methode verbessern, indem man statt Boroxyd das schwerer verdampfbare Bornitrid der Kohle zumischt.

Herr Bothe hat gefunden, daß die Asche des Elektrographits etwa dreimal weniger absorbiert, als man aus der Absorption vor der Veraschung berechnet. Wenn also die Neutronenabsorption durch Bor verursacht war, dann müßte dies wenigstens bei der Veraschung teilweise verloren gegangen sein. Dies ist möglich, da es ein leicht verdampfbares Bormonoxyd gibt.

Cadmium hat noch einen 10 mal größeren Einfangsquerschnitt als Bor. Daher wurde der Cadmiumnachweis sehr empfindlich ausgearbeitet. Es wurde festgestellt, daß in der Zuckerkohle der Cadmiumanteil von der Größenordnung 10^{-7} und sicher kleiner als 3.10^{-7} ist. 10^{-7} Anteile Cadmium würden zum Absorptionsquerschnitt der Kohle einen Beitrag von $0,0004.10^{-24}$ geben, also nur etwa den 10.Teil des von Heisenberg für Kohle berechneten Querschnitts. Auch in dem von Bothe benutzten Elektrographit ist der Cadmiumanteil kleiner als 3.10^{-7}.

Hanle.

UNCLASSIFI

Spektralanalytische Untersuchungen von Kohle, Aluminium und Beryllium.

G-153

Die von Bothe benutzte Graphitkohle wurde auf Gehalt von Bor, das von Döpel und Heisenberg benutzte Aluminium und das von Haxel und Volz benutzte Berylliumoxyd auf Gehalt von Bor und Cadmium untersucht.

Wie in einem früheren Bericht und auf der ersten Tagung über P 38 erläutert, muß bei der Überprüfung, wie weit Untersuchungen mit Neutronen durch Verunreinigungen beeinflußt werden können, besonderes Augenmerk auf Spuren von Bor und Cadmium gerichtet werden.

Kohle.

Die Versuche wurden folgendermaßen durchgeführt: Die Substanz wurde pulverisiert und in eine Höhlung von etwa 2 mm Durchmesser und 2 mm Tiefe in einen Kupferstab von 5 mm Durchmesser gebracht und im Lichtbogen gegen einen dicken massiven Kupferstab verdampft. Das Kupfer enthielt selbst Spuren von Bor. Dadurch und durch den starkken Untergrund des Bogens wurde die Meßgenauigkeit beeinträchtigt. Bei den früheren Untersuchungen konnte besonders borfreies Kupfer von Heraeus benutzt werden. Leider war dieses Kupfer verbraucht und es war unmöglich, von Heraeus neues hochgereinigtes Kupfer zu erhalten, sodaß das gewöhnliche Werkstattskupfer benutzt werden mußte.

Wurde nun in die Höhlung der Kupferelektrode Graphitpulver eingeführt, so wurden die Borlinien wesentlich verstärkt. Um den Gehalt an Bor quantitativ angeben zu können, wurden Messungen mit Vergleichssubstanzen gemacht. Diese bestanden aus möglichst Borfreier Kohle, welcher Bor in bestimmtem Verhältnis zugemischt wurde.

Die Aufnahmen wurden mit einem kleinen Zeiß'schen Photometer photometriert und zwar

1. die Kohlenstofflinie 2479,
2. die beiden Borlinien 2497 und 2498,
3. der Untergrund links und rechts und in der Mitte zwischen den Borlinien.

Auf jede Aufnahme wurde eine Hansen'sche Stufenblenden-Aufnahme photographiert und mit photometriert, mit deren Hilfe

auch bei der aus Gießen gekauften Zuckerkohle. Zunächst wurde der neue Befund dadurch erklärt, daß die Göttinger Versuche zu qualitativ gemacht waren und dadurch damals der geringe Boranteil des Zuckers dem Nachweis entgangen war. In der Meinung, daß man den Boranteil auch in der Zuckerkohle als gegeben ansehen müßte, wurde zunächst versucht, den Boranteil dadurch zu bestimmen, daß man den Borgehalt durch Zusatz von weiteren Bormengen steigerte und den Borgehalt gleich dem Anteil setzte, bei welchem eine Verdoppelung der Borintensität auftrat. Dieser Boranteil in der Zuckerkohle wurde dann bei allen Versuchen berücksichtigt. Dieses Verfahren war nicht nur recht umständlich und zeitraubend, sondern auch recht ungenau, da der Borgehalt der Zuckerkohle offenbar stark schwankte, und sich deshalb auch große Schwankungen in dem damit bestimmten Borgehalt des Bothe-Graphits ergaben. Erst nach vielen Untersuchungen gelang es, einen Zucker zu finden, welcher ebenso wie der in Göttingen früher gekaufte und die früher von Merck hergestellte Zuckerkohle praktisch kein Bor enthielt. Dieser Zucker wurde von der Firma Pfeifer & Langen, Elsdorf im Rheinland, geliefert und von dieser Firma als besonders rein bezeichnet. Die hieraus hergestellte Zuckerkohle konnte nun als Vergleichssubstanz dienen.

Als Beimischung wurde bei den ersten Versuchen Borsäure, später Borkarbid und zuletzt Bornitrid benutzt. Borsäure hat den großen Vorteil, daß man die einzelnen Mischungen dadurch herstellen kann, daß man der Zuckerkohle eine wässrige Lösung des richtigen Borgehalts beimischt und das Lösungsmittel des Breies verdampft. Es hat aber den Nachteil, daß im Lichtbogen möglicherweise ein Teil des Bors sehr schnell verdampft und dadurch ganz andere Anregungsbedingungen entstehen wie bei der Anregung des Bors im Graphit, wo das Bor als Borkarbid vorhanden ist. Daher wurde versucht, Borkarbid statt Borsäure beizumischen. Das Borkarbid ist jedoch ein grobes Pulver, welches sich wegen seiner Härte nicht feiner pulverisieren und daher nicht gut gleichmäßig mit Kohlenstoff mischen ließ. Daher wurde zuletzt Bornitrid genommen, welches fein gepulvert war und sich sicher im Lichtbogen schnell mit Kohlenstoff zu Borkarbid umsetzt, sodaß man das Bor in der gleichen chemischen Bindung wie in der Graphitkohle hat.

die Schwärzungskurven gezeichnet und die unter 1, 2 und 3 genannten Schwärzungen in Intensitäten umgerechnet wurden. Hierauf wurde der Untergrund an der Stelle der Borlinien dadurch annäherungsweise bestimmt, daß ein Mittelwert aus dem Untergrund auf der einen Seite und in der Mitte zwischen den Borlinien gebildet wurde. Dieser Wert wurde von der gemessenen Borlinienintensität abgezogen. Die Intensität der Borlinien war stets gegenüber derjenigen der Kohlenstofflinie sehr schwach, da ja mit sehr kleinen Borkonzentrationen gearbeitet wurde. Daher waren entweder die Borlinien unter- oder die Kohlenstofflinien überbelichtet. Sie konnten also niemals zugleich im günstigen linearen Schwärzungsbereich liegen. Daher wurden die Borlinien normal belichtet und die dann zu starke Kohlenstoffintensität wurde durch einen Abschwächer soweit geschwächt, daß auch sie in den normalen Schwärzungsbereich kam. Zu diesem Zweck wurde der Spalt zur Hälfte durch ein dünnes Zellophan-Häutchen bedeckt, welches die Kohlenstofflinie gerade auf die richtige Intensität abschwächte. Man erhielt dann zwei Spektren untereinander, welche zu gleicher Zeit belichtet waren. Auf dem einen Spektrum lagen die Borlinien auf dem anderen Spektrum die Kohlenstofflinie im günstigen Schwärzungsbereich.

Zunächst wurde qualitativ festgestellt, daß der Borgehalt des mir von Bothe übersandten Graphits sicher größer als 10^{-6} und kleiner als 10^{-5} (Atomanteile Bor zu Atomanteilen Kohlenstoff) war. Alsdann wurden Mischungen von borfreier Kohle mit Bor im Verhältnis 1×10^{-6}, 3×10^{-6}, 4×10^{-6}, 5×10^{-6}, 6×10^{-6}, 7×10^{-6}, 8×10^{-6} und 9×10^{-6} Atomanteile Kohlenstoff zu Atomanteilen Bor hergestellt.

Als Ausgangskohle wurde Zuckerkohle benutzt. Früher (s.den früheren Bericht und die erste Tagung über P 38) war festgestellt worden, daß Zuckerkohle praktisch borfrei sei. Die Versuche wurden damals in Göttingen sowohl mit Kohle, welche aus dort käuflichem Kandiszucker hergestellt war, als auch mit von Merck bezogener Zuckerkohle ausgeführt. Die damals benutzten Proben waren unterdessen verbraucht. Leider stellte es sich bei der Fortsetzung der Untersuchungen in Gießen heraus, daß die Zuckerkohle scheinbar doch Bor in kleinen Mengen enthielt. Dies war sowohl der Fall bei der von Merck neuerdings bezogenen Kohle als

Es zeigte sich, daß die Ergebnisse sehr stark schwankten. Dies konnte verschiedene Ursachen haben:

1. Verschiedene Anregungsbedingungen in den bei der Abbildung auf den Spalt des Spektrographen benutzten Teilen des Lichtbogens. Um diese auszuschalten wurde der Bogen nicht auf den Spalt, sondern in das Objektiv des Kollimators abgebildet und der damit verbundene Intensitätsverlust in Kauf genommen.

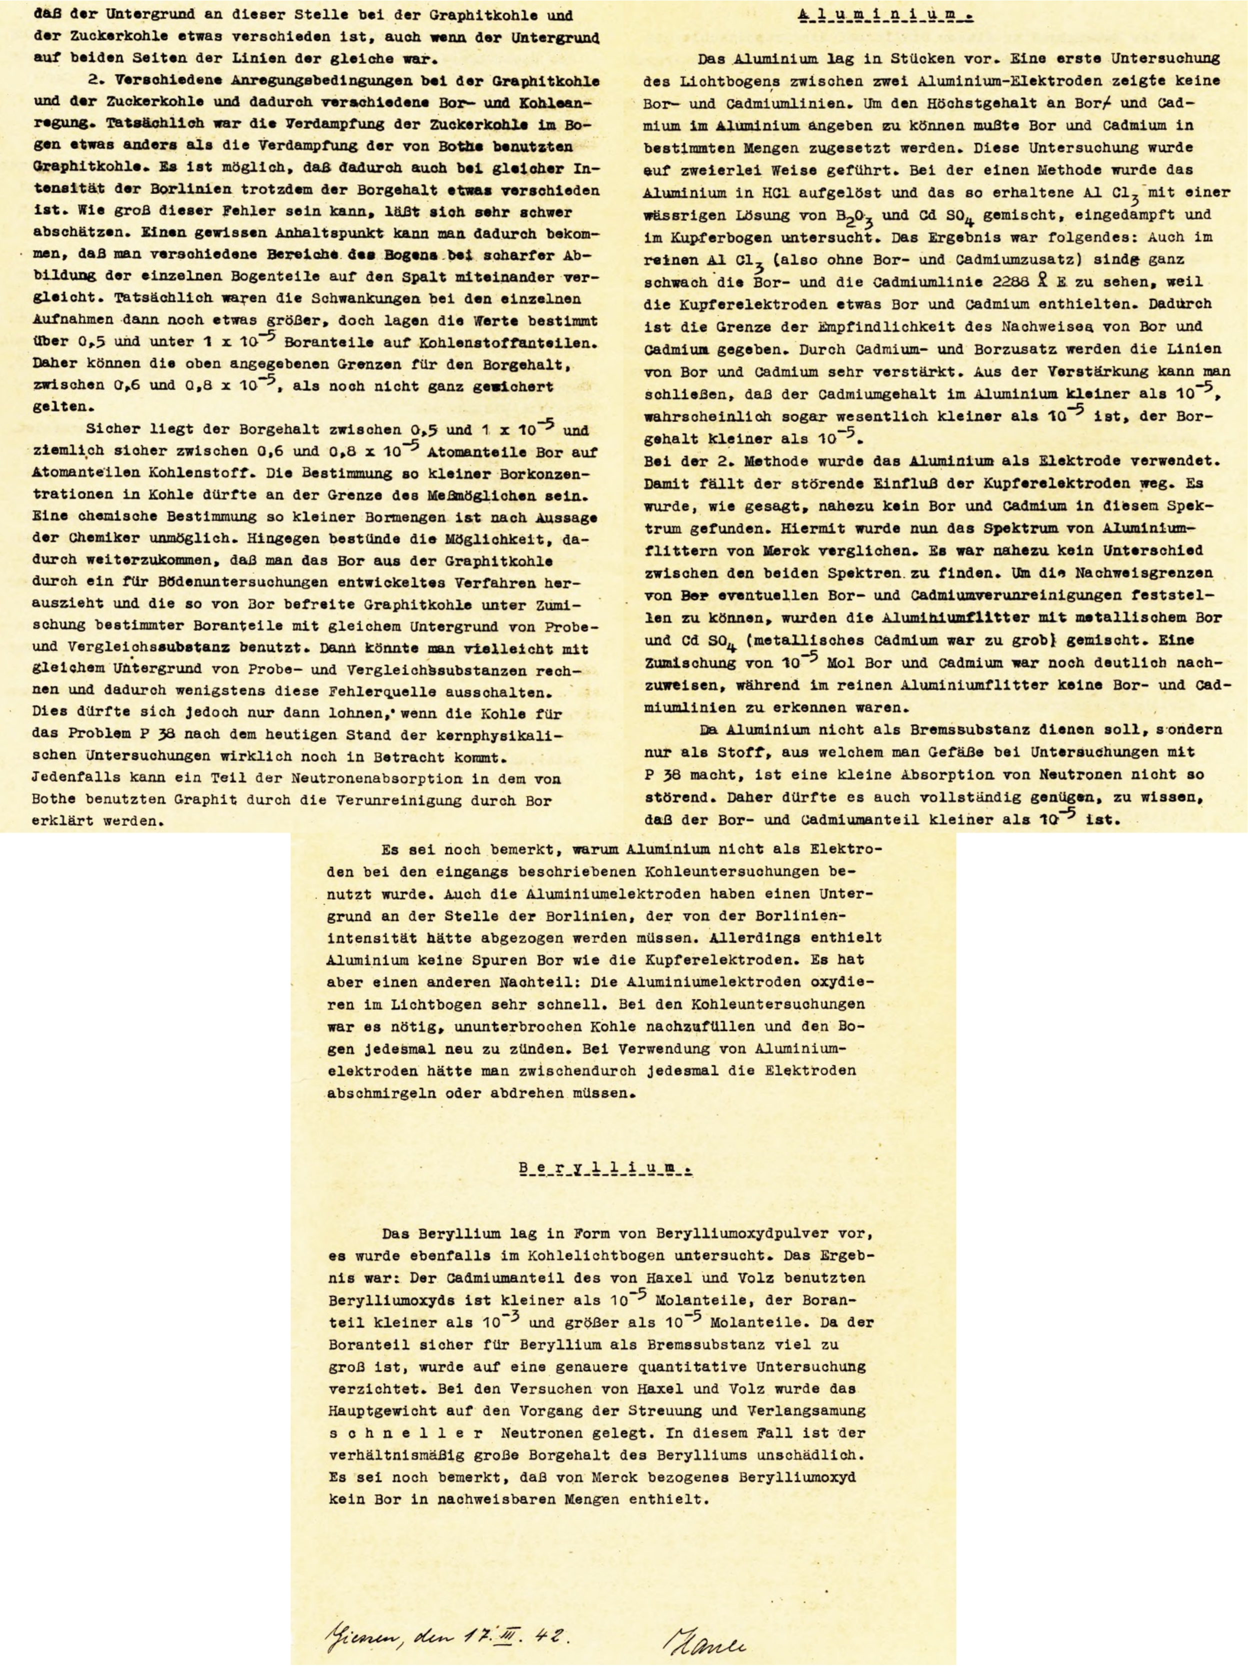
2. Verschiedener Borgehalt in den einzelnen untersuchten Proben. Dazu ist folgendes zu sagen: Den Borgehalt in den Vergleichssubstanzen ganz einheitlich zu machen, war schlechterdings unmöglich. Dafür ist auch das der Kohle zugesetzte Bornitrid nicht genügend feinkörnig. Man muß immer bedenken, daß man es mit sehr kleinen Borkonzentrationen zu tun hat. Um festzustellen, ob der Borgehalt in dem von Bothe benutzten Graphit an verschiedenen Stellen verschieden ist, haben wir verschiedene Stücke verglichen. Die Schwankungen waren dabei nicht größer als sonst. Hingegen zeigte sich ein eindeutiger Unterschied zwischen dem bei der Zersägung der Stücke abfallenden feinen Staub und dem durch Mörserung aus den kompakten Stücken gewonnenen Pulver. Der Borgehalt des Pulvers war um 10-20 % größer als der des Staubes.

Ergebnis: Das Ergebnis der Mittelbildung von etwa 10 guten Aufnahmereihen war folgendes: Der Borgehalt des Staubes ist $<$ als $0{,}7 \times 10^{-5}$ und $> 0{,}6 \times 10^{-5}$. Der Borgehalt des kompakten und dann gepulverten Materials ist $< 0{,}8 \times 10^{-5}$ und $> 0{,}6 \times 10^{-5}$.

Kritik der Untersuchungen: Zu dem Ergebnis, daß der Borgehalt $> 0{,}6 \times 10^{-6}$ und $< 0{,}8 \times 10^{-5}$ sei, ist folgendes zu sagen: Die Grenzen des angegebenen Bereichs sind durch die Schwankungen der einzelnen Messungen gegeben. Was dabei nicht berücksichtigt werden konnte, sind etwaige systematische Fehler. Als solche sind zu nennen:

1. Der Einfluß des Untergrunds. Da der Untergrund bei dem Bor enthaltenden Graphit an der Stelle der Borlinien nicht bestimmt werden konnte, wurde, wie beschrieben, auf beiden Seiten der Borlinien der Untergrund gemessen und der Mittelwert als Untergrund an der Stelle der Borlinien eingesetzt. Dies muß nicht unbedingt richtig sein. Es ist möglich, daß eine schwache Verunreinigungslinie sich an dieser Stelle befindet und

Figure D.525: Wilhelm Hanle. *Spectroscopic Analysis of Carbon, Aluminum, and Beryllium.* 1942. [G-153]



daß der Untergrund an dieser Stelle bei der Graphitkohle und der Zuckerkohle etwas verschieden ist, auch wenn der Untergrund auf beiden Seiten der Linien der gleiche war.

2. Verschiedene Anregungsbedingungen bei der Graphitkohle und der Zuckerkohle und dadurch verschiedene Bor- und Kohleanregung. Tatsächlich war die Verdampfung der Zuckerkohle im Bogen etwas anders als die Verdampfung der von Bothe benutzten Graphitkohle. Es ist möglich, daß dadurch auch bei gleicher Intensität der Borlinien trotzdem der Borgehalt etwas verschieden ist. Wie groß dieser Fehler sein kann, läßt sich sehr schwer abschätzen. Einen gewissen Anhaltspunkt kann man dadurch bekommen, daß man verschiedene Bereiche des Bogens bei scharfer Abbildung der einzelnen Bogenteile auf den Spalt miteinander vergleicht. Tatsächlich waren die Schwankungen bei den einzelnen Aufnahmen dann noch etwas größer, doch lagen die Werte bestimmt über 0,5 und unter 1×10^{-5} Boranteile auf Kohlenstoffanteilen. Daher können die oben angegebenen Grenzen für den Borgehalt, zwischen 0,6 und $0{,}8 \times 10^{-5}$, als noch nicht ganz gesichert gelten.

Sicher liegt der Borgehalt zwischen 0,5 und 1×10^{-5} und ziemlich sicher zwischen 0,6 und $0{,}8 \times 10^{-5}$ Atomanteile Bor auf Atomanteilen Kohlenstoff. Die Bestimmung so kleiner Borkonzentrationen in Kohle dürfte an der Grenze des Meßmöglichen sein. Eine chemische Bestimmung so kleiner Bormengen ist nach Aussage der Chemiker unmöglich. Hingegen bestünde die Möglichkeit, dadurch weiterzukommen, daß man das Bor aus der Graphitkohle durch ein für Bödenuntersuchungen entwickeltes Verfahren herauszieht und die so von Bor befreite Graphitkohle unter Zumischung bestimmter Boranteile mit gleichem Untergrund von Probe- und Vergleichssubstanz benutzt. Dann könnte man vielleicht mit gleichem Untergrund von Probe- und Vergleichssubstanzen rechnen und dadurch wenigstens diese Fehlerquelle ausschalten. Dies dürfte sich jedoch nur dann lohnen, wenn die Kohle für das Problem P 38 nach dem heutigen Stand der kernphysikalischen Untersuchungen wirklich noch in Betracht kommt. Jedenfalls kann ein Teil der Neutronenabsorption in dem von Bothe benutzten Graphit durch die Verunreinigung durch Bor erklärt werden.

Aluminium.

Das Aluminium lag in Stücken vor. Eine erste Untersuchung des Lichtbogens zwischen zwei Aluminium-Elektroden zeigte keine Bor- und Cadmiumlinien. Um den Höchstgehalt an Bor- und Cadmium im Aluminium angeben zu können mußte Bor und Cadmium in bestimmten Mengen zugesetzt werden. Diese Untersuchung wurde auf zweierlei Weise geführt. Bei der einen Methode wurde das Aluminium in HCl aufgelöst und das so erhaltene $Al\,Cl_3$ mit einer wässrigen Lösung von B_2O_3 und $Cd\,SO_4$ gemischt, eingedampft und im Kupferbogen untersucht. Das Ergebnis war folgendes: Auch im reinen $Al\,Cl_3$ (also ohne Bor- und Cadmiumzusatz) sind ganz schwach die Bor- und die Cadmiumlinie 2288 Å E zu sehen, weil die Kupferelektroden etwas Bor und Cadmium enthielten. Dadurch ist die Grenze der Empfindlichkeit des Nachweises von Bor und Cadmium gegeben. Durch Cadmium- und Borzusatz werden die Linien von Bor und Cadmium sehr verstärkt. Aus der Verstärkung kann man schließen, daß der Cadmiumgehalt im Aluminium kleiner als 10^{-5}, wahrscheinlich sogar wesentlich kleiner als 10^{-5} ist, der Borgehalt kleiner als 10^{-5}.
Bei der 2. Methode wurde das Aluminium als Elektrode verwendet. Damit fällt der störende Einfluß der Kupferelektroden weg. Es wurde, wie gesagt, nahezu kein Bor und Cadmium in diesem Spektrum gefunden. Hiermit wurde nun das Spektrum von Aluminiumflittern von Merck verglichen. Es war nahezu kein Unterschied zwischen den beiden Spektren zu finden. Um die Nachweisgrenzen von Ber eventuellen Bor- und Cadmiumverunreinigungen feststellen zu können, wurden die Alumihiumflitter mit metallischem Bor und $Cd\,SO_4$ (metallisches Cadmium war zu grob) gemischt. Eine Zumischung von 10^{-5} Mol Bor und Cadmium war noch deutlich nachzuweisen, während im reinen Aluminiumflitter keine Bor- und Cadmiumlinien zu erkennen waren.

Da Aluminium nicht als Bremssubstanz dienen soll, sondern nur als Stoff, aus welchem man Gefäße bei Untersuchungen mit P 38 macht, ist eine kleine Absorption von Neutronen nicht so störend. Daher dürfte es auch vollständig genügen, zu wissen, daß der Bor- und Cadmiumanteil kleiner als 10^{-5} ist.

Es sei noch bemerkt, warum Aluminium nicht als Elektroden bei den eingangs beschriebenen Kohleuntersuchungen benutzt wurde. Auch die Aluminiumelektroden haben einen Untergrund an der Stelle der Borlinien, der von der Borlinienintensität hätte abgezogen werden müssen. Allerdings enthielt Aluminium keine Spuren Bor wie die Kupferelektroden. Es hat aber einen anderen Nachteil: Die Aluminiumelektroden oxydieren im Lichtbogen sehr schnell. Bei den Kohleuntersuchungen war es nötig, ununterbrochen Kohle nachzufüllen und den Bogen jedesmal neu zu zünden. Bei Verwendung von Aluminiumelektroden hätte man zwischendurch jedesmal die Elektroden abschmirgeln oder abdrehen müssen.

Beryllium.

Das Beryllium lag in Form von Berylliumoxydpulver vor, es wurde ebenfalls im Kohlelichtbogen untersucht. Das Ergebnis war: Der Cadmiumanteil des von Haxel und Volz benutzten Berylliumoxyds ist kleiner als 10^{-5} Molanteile, der Boranteil kleiner als 10^{-3} und größer als 10^{-5} Molanteile. Da der Boranteil sicher für Beryllium als Bremssubstanz viel zu groß ist, wurde auf eine genauere quantitative Untersuchung verzichtet. Bei den Versuchen von Haxel und Volz wurde das Hauptgewicht auf den Vorgang der Streuung und Verlangsamung schneller Neutronen gelegt. In diesem Fall ist der verhältnismäßig große Borgehalt des Berylliums unschädlich. Es sei noch bemerkt, daß von Merck bezogenes Berylliumoxyd kein Bor in nachweisbaren Mengen enthielt.

E. Graphite

[High-quality graphite was widely used for high-temperature exhaust steering rudders on the A-4 (V-2) and other rockets, and was used for making electrodes, filters, and other components too. However, graphite could also have been quite useful as a neutron moderator to slow down neutrons and promote chain reactions in a fission reactor. The following documents illustrate that wartime production of graphite was widespread and sophisticated.]

Acheson Graphite Corporation to Frank Hodson. 29 July 1942. [NARA RG 77, Entry UD-22A, Box 169, Folder 32.32 Germ. Ind. TA]

Continental European Electrode Plants

Further to my letters of July 24th and 25th, I am glad to send along what information and estimates we have in regard to commercial electrode plants in Continental Europe.

Germany

Graphite

According to estimates made by our people in Europe at the end of 1939, the graphite electrode production in Germany during that year was approximately as follows:

Siemens-Planiawerke, Meitingen	8,500 tons
Conradty, Kolbermoor	2,000 ”
I. G. Farben, Bitterfeld	5,000 ”
	15,500 tons

In 1939 the German industry was already substantially on war production but a fifty percent increase over the above figure might not be unreasonable for the present time. This would bring the total to about 23,000 tons. [...]

Coal Electrodes

Our estimate of the production capacity of the three German firms is as follows:

Siemens-Planiawerke, Ratibor	50,000 tons
Conradty, Nürnberg	6,000 ”
I. G. Farben, Bitterfeld	3,500 ”
	59,500 tons

SECRET

CONFIDENTIAL

Dear Mr. Hodson:

Continental European Electrode Plants

Further to my letters of July 24th and 25th, I am glad to send along what information and estimates we have in regard to commercial electrode plants in Continental Europe.

Germany

Graphite

According to estimates made by our people in Europe at the end of 1939, the graphite electrode production in Germany during that year was approximately as follows:

Siemens-Planiawerke, Meitingen	8,500 tons
Conradty, Kolbermoor	2,000 "
I. G. Farben, Bitterfeld	5,000 "
	15,500 tons

In 1939 the German industry was already substantially on war production but a fifty percent increase over the above figure might not be unreasonable for the present time. This would bring the total to about 23,000 tons.

The largest electrode producer is Siemens-Planiawerke and their largest factory is at Ratibor, Silesia. This is their plant for the manufacture of coal electrodes and they also produce gas baked petroleum coke carbons which are graphitized at Meitingen, Bavaria. This Meitingen plant is simply a graphitizing and finishing plant and, as far as we know, is the only graphite electrode plant operated by Siemens-Planiawerke. At Lichtenberg, about ten miles from Berlin, is a large Siemens plant specializing the production of brushes, lighting and projector carbons, and finishing of miscellaneous special carbon and graphite products. Siemens' administration, Works Management,

Authority 917017

NARA RG 77, Entry UD-22A, Box 169, Folder 32.32 Germ. Incl. TA

Mr. Frank Hodson July 29th, 1942.

and Sales Departments as well as the Research Department are located at Lichtenberg.

Conradty - Nürnberg

A very large plant for the production of large coal electrodes, brushes, lighting, projector, and miscellaneous small carbon products, situated about ten miles out from Nürnberg. I do not remember the name of the small village at which the plant is located and their German catalog does not give the name. The plant covers a wide area, but for many years only a small part of the total coal electrode capacity has been used. There is equipment for milling, mixing, pressing, and baking coal electrodes in the sizes used for the production of alloys and carbide. This plant also supplies the gas baked petroleum coke blanks for their graphitizing plants at Kilbermoor in Bavaria and Affoltern in Switzerland. The brush, lighting, projector, and battery carbon equipment is considered modern and complete.

Conradty - Kilbermoor, Bavaria

This plant is located between Munich and Rosenheim and is a graphitizing and finishing plant. The baked blanks are supplied by the Nürnberg plant.

I. G. Farben (German Dye Trust), Bitterfeld

This is a complete graphite plant with milling, mixing, pressing, baking, graphitizing, and finishing equipment for graphite anodes; also possibly molding equipment and baking capacity for large coal electrodes for alloy and phosphorous furnaces operated by the I. G. group. The electrode factory is situated in the large I. G. chemical plant at Bitterfeld, on the main Halle Berlin railroad, about 50 miles S. W. of Berlin and 10 miles N. E. of Halle. In recent years this electrode plant has supplied most of the graphite anodes required by the German alkali chlorine industry, a large part of which is controlled by I. G. Farben. It has always been understood that most of the magnesium metal produced in Germany is "Elektron" metal, made by the I. G. Farben process and that all of the anodes required in this process are manufactured at Bitterfeld.

Coal Electrodes

Our estimate of the production capacity of the three German firms is as follows:

Siemens-Planiawerke, Ratibor	50,000 tons
Conradty, Nurnberg	6,000 "
I. G. Farben, Bitterfeld	3,500 "
	59,500 tons

NARA RG 77, Entry UD-22A, Box 169, Folder 32.32 Germ. Incl. TA

- 3 -

Mr. Frank Hodson July 29th, 1942.

Italy

There are three commercial electrode plants in Italy.

S. A. Elettrografite di Forno Allione, which is owned by us, is located at Forno Allione about fifty miles north of Brescia, and some six miles south of the town of Edolo. It is fairly close to the Swiss border. At the time our manager left in January, 1941, the capacity was rated at 4,800 metric tons.

Another graphite electrode factory is operated by S. A. Talco e Grafite Val Chisone at the town of Pinerolo, which is south-west of Turin. Their electrodes are made from natural graphite and we estimate their capacity at about 4,000 tons per year.

A carbon electrode plant is operated by Elettrocarboni (owned by Siemens-Planiawerke) at Ascoli Piceno, a town north east of Rome not far from the east coast. We estimate this plant to have a capacity of about 5,000 tons.

There is also a carbon plant at Narni, almost due north of Rome, which we understand is operated by Montecatini to produce anodes for their aluminum plants.

France

The graphite electrode plant in which we are interested is operated by Compagnie Industrielle Savoie-Acheson at Notre Dame-de-Briancon in the Department of Savoie. It is about four miles north-west of Moutiers. The plant has a rated capacity of about 7,000 metric tons of graphite electrodes a year.

At the same location a separate company, Societe des Electrodes de la Savoie, operates a carbon electrode plant estimated to be capable of producing 5,000 to 7,000 metric tons per year.

The latter company also has a coal carbon electrode plant at Venissieux, a town southeast of Lyons. The capacity is estimated at 5,000 to 6,000 metric tons per year.

In none of the above have we attempted to include electrode plants for the manufacture of aluminum anodes except the one at Narni, Italy. As you know, these electrode plants are generally located close to the aluminum plants.

Hoping that this information will be of some value, I am,

Yours very truly,

/s/ H.P. Martin
Vice President

FIAT 397. *Survey of the Carbon and Graphite Electrode Industry of Germany.* With two supplements. pp. 6, 11.

[...] The discussions with the SIEMENS technical organization showed the possession of the extensive empirical know-how needed for successful operation in this industry, compounded as it must be of experience and science. Thus, as respects empirical know-how, the German industry could be rated as perhaps about equal to the U.S.

As far as scientific know-how and study of the fundamentals of carbon technology are concerned, the German industry has depended very largely upon collaboration with academic researchers, mainly with Prof. ULRICH HOFFMANN. The German industry has directed its technical work more along development lines. [...]

The following tabulation shows the total German production capacity for the baked basic stock for either carbon or graphite electrodes, comparing the installed capacity near the end of the war with that now available in the U.S. Zone [of Germany]. There is no other baked electrode capacity except at some of the aluminum plants which produce their own special electrodes.

The tabulation is in terms of baked weight. The indicated tons are of 1,000 kg. = 2,200 lb.

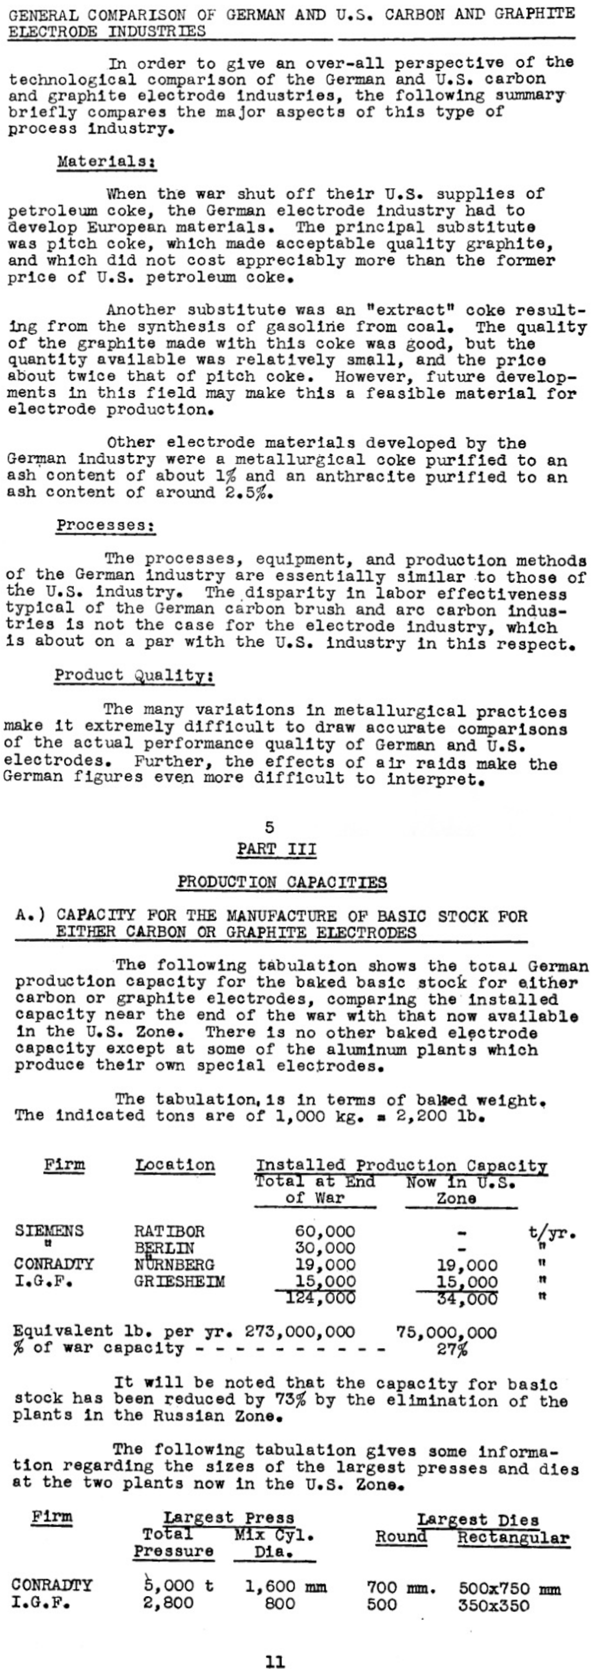
Firm	Location	Installed	Production	Capacity
		Total at End of War	Now in U.S. Zone	
SIEMENS	RATIBOR	60,000	–	t/yr.
”	BERLIN	30,000	–	”
CONRADTY	NÜRNBERG	19,000	19,000	”
I.G.F.	GRIESHEIM	15,000	15,000	”
		124,000	34,000	”

[See document photos on p. 4115.

Note that this postwar U.S. survey found that by the end of the war, the actual German annual production of graphite was even larger than what the United States had estimated during the war.

Conventional historians often claim that the German nuclear program foolishly rejected graphite as a reactor moderator, instead focusing only on heavy water. Heavy water has many advantages over graphite (p. 4029), yet there is evidence that the German nuclear program used graphite too. I.G. Farben's Bitterfeld facility was mass-producing both graphite (p. 4110) and heavy water (p. 4050) as well as other nuclear-related materials (pp. 4128, 4133, 4136). Similarly, Griesheim plants were producing both graphite (pp. 4114–4116) and heavy water (pp. 4066–4067), with other nuclear-related facilities such as Degussa in the same area [Hayes 2004; Nagel 2016]. Graphite was also mass-produced at the Siemens Plania Werke in Racibórz/Ratibor, Poland (pp. 4110–4114), near a reported heavy water plant at Auschwitz (pp. 4069, 4452) and reported uranium enrichment plants at Opava and Ostrava (p. 3749).]

FIAT 397. *Survey of the Carbon and Graphite Electrode Industry of Germany*



GENERAL COMPARISON OF GERMAN AND U.S. CARBON AND GRAPHITE ELECTRODE INDUSTRIES

In order to give an over-all perspective of the technological comparison of the German and U.S. carbon and graphite electrode industries, the following summary briefly compares the major aspects of this type of process industry.

Materials:

When the war shut off their U.S. supplies of petroleum coke, the German electrode industry had to develop European materials. The principal substitute was pitch coke, which made acceptable quality graphite, and which did not cost appreciably more than the former price of U.S. petroleum coke.

Another substitute was an "extract" coke resulting from the synthesis of gasoline from coal. The quality of the graphite made with this coke was good, but the quantity available was relatively small, and the price about twice that of pitch coke. However, future developments in this field may make this a feasible material for electrode production.

Other electrode materials developed by the German industry were a metallurgical coke purified to an ash content of about 1% and an anthracite purified to an ash content of around 2.5%.

Processes:

The processes, equipment, and production methods of the German industry are essentially similar to those of the U.S. industry. The disparity in labor effectiveness typical of the German carbon brush and arc carbon industries is not the case for the electrode industry, which is about on a par with the U.S. industry in this respect.

Product Quality:

The many variations in metallurgical practices make it extremely difficult to draw accurate comparisons of the actual performance quality of German and U.S. electrodes. Further, the effects of air raids make the German figures even more difficult to interpret.

PART III

PRODUCTION CAPACITIES

A.) CAPACITY FOR THE MANUFACTURE OF BASIC STOCK FOR EITHER CARBON OR GRAPHITE ELECTRODES

The following tabulation shows the total German production capacity for the baked basic stock for either carbon or graphite electrodes, comparing the installed capacity near the end of the war with that now available in the U.S. Zone. There is no other baked electrode capacity except at some of the aluminum plants which produce their own special electrodes.

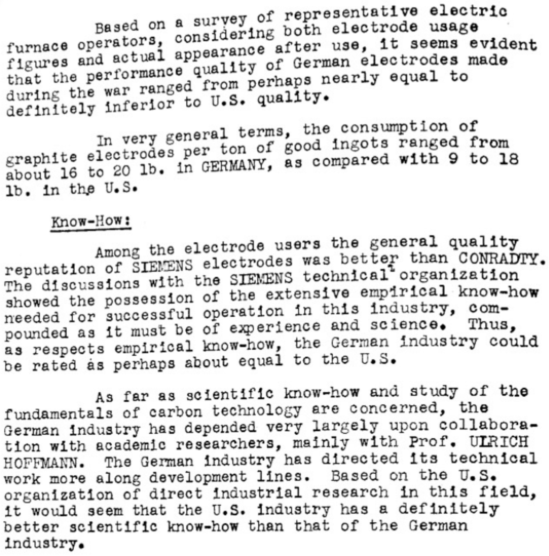
The tabulation is in terms of baked weight. The indicated tons are of 1,000 kg. = 2,200 lb.

Firm	Location	Installed Production Capacity Total at End of War	Installed Production Capacity Now in U.S. Zone	
SIEMENS	RATIBOR	60,000	-	t/yr.
"	BERLIN	30,000	-	"
CONRADTY	NÜRNBERG	19,000	19,000	"
I.G.F.	GRIESHEIM	15,000	15,000	"
		124,000	34,000	"
Equivalent lb. per yr.		273,000,000	75,000,000	
% of war capacity - - - - - - - - - -			27%	

It will be noted that the capacity for basic stock has been reduced by 73% by the elimination of the plants in the Russian Zone.

The following tabulation gives some information regarding the sizes of the largest presses and dies at the two plants now in the U.S. Zone.

Firm	Largest Press Total Pressure	Largest Press Max Cyl. Dia.	Largest Dies Round	Largest Dies Rectangular
CONRADTY	5,000 t	1,600 mm	700 mm.	500x750 mm
I.G.F.	2,800	800	500	350x350



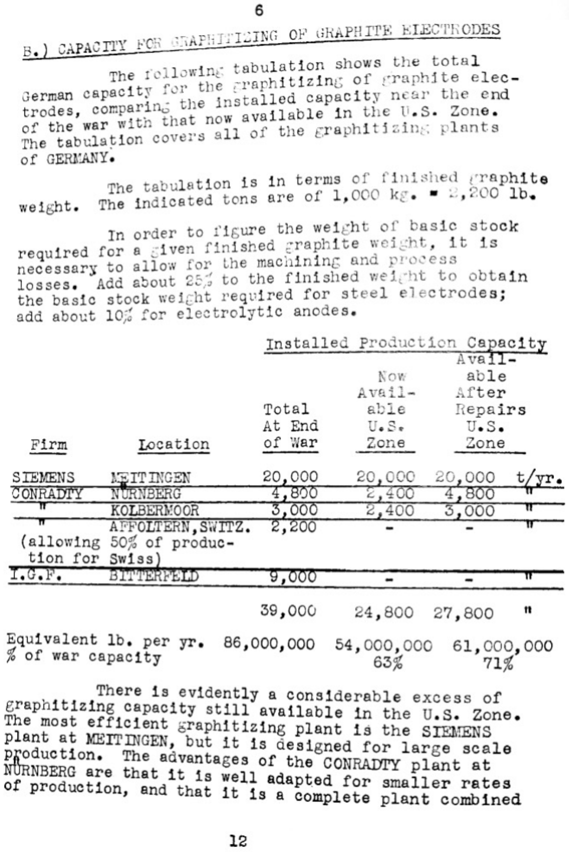
Based on a survey of representative electric furnace operators, considering both electrode usage figures and actual appearance after use, it seems evident that the performance quality of German electrodes made during the war ranged from perhaps nearly equal to definitely inferior to U.S. quality.

In very general terms, the consumption of graphite electrodes per ton of good ingots ranged from about 16 to 20 lb. in GERMANY, as compared with 9 to 18 lb. in the U.S.

Know-How:

Among the electrode users the general quality reputation of SIEMENS electrodes was better than CONRADTY. The discussions with the SIEMENS technical organization showed the possession of the extensive empirical know-how needed for successful operation in this industry, compounded as it must be of experience and science. Thus, as respects empirical know-how, the German industry could be rated as perhaps about equal to the U.S.

As far as scientific know-how and study of the fundamentals of carbon technology are concerned, the German industry has depended very largely upon collaboration with academic researchers, mainly with Prof. ULRICH HOFFMANN. The German industry has directed its technical work more along development lines. Based on the U.S. organization of direct industrial research in this field, it would seem that the U.S. industry has a definitely better scientific know-how than that of the German industry.



B.) CAPACITY FOR GRAPHITIZING OF GRAPHITE ELECTRODES

The following tabulation shows the total German capacity for the graphitizing of graphite electrodes, comparing the installed capacity near the end of the war with that now available in the U.S. Zone. The tabulation covers all of the graphitizing plants of GERMANY.

The tabulation is in terms of finished graphite weight. The indicated tons are of 1,000 kg. = 2,200 lb.

In order to figure the weight of basic stock required for a given finished graphite weight, it is necessary to allow for the machining and process losses. Add about 25% to the finished weight to obtain the basic stock weight required for steel electrodes; add about 10% for electrolytic anodes.

Firm	Location	Installed Production Capacity Total At End of War	Installed Production Capacity Now Available U.S. Zone	Installed Production Capacity Available After Repairs U.S. Zone	
SIEMENS	MEITINGEN	20,000	20,000	20,000	t/yr.
CONRADTY	NÜRNBERG	4,800	2,400	4,800	"
"	KOLBERMOOR	3,000	2,400	3,000	"
" (allowing 50% of production for Swiss)	AFFOLTERN, SWITZ.	2,200	-	-	"
I.G.F.	BITTERFELD	9,000	-	-	"
		39,000	24,800	27,800	"
Equivalent lb. per yr.		86,000,000	54,000,000	61,000,000	
% of war capacity			63%	71%	

There is evidently a considerable excess of graphitizing capacity still available in the U.S. Zone. The most efficient graphitizing plant is the SIEMENS plant at MEITINGEN, but it is designed for large scale production. The advantages of the CONRADTY plant at NÜRNBERG are that it is well adapted for smaller rates of production, and that it is a complete plant combined

F. Fluorine

[Fluorine was used for various industrial chemical production processes, but it also would have been essential for producing uranium hexafluoride for the enrichment of uranium-235. The following documents demonstrate large-scale production of fluorine.

For information on wartime German production of uranium hexafluoride for uranium enrichment, see pp. 3478–3493.]

Philip Morrison to Samuel K. Allison. 20 December 1943. Report on Enemy Physics Literature: Survey Report P. [NARA RG 77, Entry UD-22A, Box 170, Folder 32.60-1 GERMANY: Summary Reports (1944)]

The nearly unique position of fluorine in most successful separation schemes leads to an interest in the state of fluorine chemistry. (The examination of this point is the work of Dr. J. Katz of Seaborg's division.)

The general interest of German chemical industry in inorganic preparations, and probably also early preparation for chemical warfare, has put German fluorine chemistry considerably ahead of our own. In 1939 it was possible to procure fluorine gas in bombs(18) from the inorganic section of the I.G. at Leverkusen, near Frankfurt a. M. It is still not easy to do this in the United States. The number of trained inorganic chemists and even of fluorine workers in Germany was greater then than the number now available to the three projects in this country. A few of the leading men and institutions are:

H. v. Wartenberg	Göttingen
Wilhelm Klemm (Klemm has been interested in the chemistry of 93.)	Danzig-Langfuhr
Wilhelm Biltz	Hanover u. Göttingen
Eduard Zintl	Darmstadt

There is little doubt that the I.G. would be the constructor of any large-scale separation plant. Such a plant would probably be at Leverkusen, near Frankfurt. Frankfurt a. M. is the center of the German chemical industry; the Deutsche Gold- und Silber-Scheide-Anstalt A.G. is there as well. One might speculate that Bothe's and Rajewsky's groups form the physics staff—with the K.W.I. f. Physik the Y [Los Alamos] equivalent—for a Leverkusen or Frankfurt plant.

(Can the information bearing on this region be especially searched for clues?) [...]

[See document photos on p. 4121.

I.G. Farben produced large quantities of fluorine. DeGussa, Auer, Roges, and other companies produced uranium. To produce uranium hexafluoride, it would have been necessary for I.G. Farben to collaborate with those companies. When the I.G. Farben director, Dr. Halberland, was interrogated about such collaborations, he refused to provide answers, but apparently indicated that they did exist.

Notes from this interrogation were considered so important regarding Germany's nuclear program that they were placed in the files of Leslie Groves's Foreign Intelligence Unit of the U.S. Manhattan Project.]

G - Res TA

HEADQUARTERS
EUROPEAN THEATER OF OPERATIONS
UNITED STATES ARMY
Alsos Mission
APO 887

5 April 1945.

SUBJECT: Interrogation of Doctor Halberland.

1. Doctor Halberland, technical director of the lower Rhine division of the I. G. Farben Company, was located at I. G. Farben's plant at Uerdingen on the Rhine. Uerdingen is one-half mile northeast of Krefeld. He is at present undetained but is living in Uerdingen in an air raid shelter across the street from the main entrance of the I. G. Farben Company plant. He is a chemist of eighteen years experience and technical director of four large I. G. Farben Company plants, among which are the large Levurkusen plant and that at Uerdingen. He also supervised the work at the Knapsack plant. He went to the United States in 1937 where he visited the duPont Company, Bayer Company, and other companies.

2. The Uerdingen plant produces various inorganic chemicals such as sulphuric acid, sodium dichromate, hydrochloric acid, chlorine (10,000 tons per month) as well as various organic chemicals such as acetanilide, benzene, toluene, nitrobenzene and previously produced war gas (adamsite) but this production has been discontinued. When questioned further on war gas production, Dr. Halberland indicated that most of war gas production in Germany is now centered at Durenfort. The four major research centers of I. G. Farben Company are located at the plants at Levurkusen, Bitterfeld, Ludwigshafen and Höchst.

3. Dr. Halberland being scientific director of Levurkusen knows a great deal about research work done there. The key personnel at Levurkusen are: Dr. Burgenmann, director; Dr. Beyar, scientific laboratory director; Dr. Klebert, inorganic chemicals; Drs. Wink, Ludwig, Bömmer, organic chemicals; Dr. Albers, photographic materials; Dr. Conrad, rubber plant. Large quantities of fluor~~ine~~ are produced at Levurkusen as well as Germany's major production of titanium.

4. Dr. Halberland knew of no special research station operated by I. G. Farben which would have been under government supervision. When questioned about university connections, Dr. Halberland stated that research work was placed in various universities. Professor Alder of Cologne was one consultant of which Halberland knew.

5. It is believed that a great deal more information about I. G. Farben organization, etc., may be obtained from Halberland. According to him, the administrative papers and files of the Uerdingen plant are still intact and under lock and key. His secretary, Fraulein Klein, Uerdingstr. 374, Krefeld, knows of the filing system and location of all documents and has the keys to the files. Troops are billeted in the lower part of the administrative offices and the building has suffered no noticeable bomb damage. We checked with the troop commander and discovered that he had been instructed not to disturb files, etc., in the upper offices. The building overlooks the Rhine and therefore must be exploited with caution. Questioning of Dr. Halberland seemed to bring very cautious answers. Further interrogation should be carried on with some tact. Dr. Halberland is keenly interested in seeing that files are undisturbed, so that the plant may reopen with the least difficulty. In his opinion, eight days only would be required to bring the plant to 70 per cent production.

6. Dr. Halberland is convinced that Germany has lost the war and thinks it foolish for the Germans to continue fighting. He therefore might reveal more information if interrogated by the proper personnel. Halberland was questioned about I. G. Farben's relation with other companies such as DeGussa, Auer, Roges, etc., but no positive answers were obtained. When questioned about the sources of interests in rare materials, he was very vague but mentioned that rare earths come from the Black Forest region. An immediate survey of the files at Uerdingen plant seems advisable. Such a survey might provide information for further interrogation of Dr. Halberland.

BIOS 1595.
German Fluorine and Fluoride Industry

5.

Riedel de Haen System

The first system has been developed by Dr. Siemans of Riedel de Haen. This has been installed at Vereinigte Flusspatgruben where six sets of retorts were erected complete with absorption systems and redistillation equipment and a further six in process of erection. The completed factory would have been capable of producing at least 6000 tons of pure anhydrous hydrofluoric acid per year.

Since there are available 18 redistillation equipments, each capable of distilling approximately one ton of 92-95% HF in 6 hours, adequate plant was provided for repeated distillation in order to obtain a very high grade anhydrous hydrofluoric acid. It was anticipated that a purity of 99.99% HF would be obtained after redistillation.

I.G. Farben Industries System

The system developed at the I.G. Works was a relatively long rotating kiln, gas-fired, with a worm as agitator. The completed plant at Leverkusen Works is capable of producing hydrofluoric acid at 80% strength equivalent to 9,600 tons per year, of which 960 tons per year would be 98-100% without redistillation. The acid strength was guaranteed not less than 98% and contained approximately 1% as fluosulphonic acid and 0.10% silica, presumably as H_2SiF_6. Detailed analysis and methods are attached as appendix.

Oppau Works, Ludwigshafen

An unique system has been installed at the I.G.Oppau Works for the production of cryolite from low grade fluorspar. The process is cyclic and appears very efficient. The process proceeds according to the following reactions :-

1. $3\ CaF_2 + SiO_2 + 3H_2SO_4 = H_2SiF_6 + 3CaSO_4 + 2H_2O$
2. $H_2SiF_6 + 6NH_3 + 2H_2O = 6NH_4F + SiO_2$ (Solid)
3. $6NH_4F + Na_3AlO_3 = Na_3AlF_6 + 6NH_3 + 3H_2O$

6.

Fluorides

The production of fluorides from hydrofluoric acid (aqueous) and the corresponding metallic salt followed the conventional procedure. In the older plants the processes were very crude, but in the new plants, particularly at Leverkusen, sufficient plant of suitable design has been installed for the production of all the fluorides, bifluorides, fluoborates and silica fluorides.

At the Saline Ludwigshalle Works, hydrofluoric acid was purified from silica and H_2SiF_6 by the precipitation of sodium silico fluoride by sodium carbonate and the sodium silico fluoride recovered and sold for use in the manufacture of ceramics.

Fluorine and Fluorine Compounds

The production of fluorine and fluorine compounds with Cl_2 and other elements was proceeding rapidly and on a large scale when the war terminated. At Falkenhagen, Berlin, plant had been erected for the production of 720 tons fluorine per annum. When the Russian Army was approaching the Works, the entire plant was dismantled and despatched to Stulln in Bavaria, where it was hoped to re-erect on the site of the plant producing anhydrous hydrofluoric acid. There were 60 cells available, together with spares and all the electrical equipment to provide each cell with 12 volts D.C. and 2500 amps each.

Chlorine Trifluoride

The reaction vessels for the production of chlorine trifluoride were around the factory and a detailed description of the process was obtained, this, together with sketches, are included in the account of the processes.

Fluorine at Leverkusen

During discussions with Prof. Helfrich and Dr. Schmidt-Dupont at Bonn University, information was obtained indicating that I.G. at Leverkusen had produced fluorine and other fluorine compounds for general use and

7.

that in conjunction with the University at Gottingen, investigations had been conducted into the problems of fluorine production, together with those associated with metallic fluorides of the earths and rare earths. The fluorine cell at Leverkusen was of approximately the same capacity as those erected at Falkenhagen operating at 2500 amps and 11-12 volts with an output of 1 kilo per hour. By using special electrodes they had overcome the polarisation troubles which had been experienced at Falkenhagen. The electrolytes employed in the cells, however, were very different. At Falkenhagen the ratio of 1KF to 1 HF was employed together with the graphite anode. At Leverkusen 1KF to 2.5 HF was employed, utilising a petrol coke anode. The use of these different electrodes necessitated independent cell design.

SUBJECT: German Aluminum, production and fabrication; German Magnesium.

TO: Chief, Chemical Warfare Service, Washington 25, D. C.

THRU: G-2, War Department General Staff.

1. There is reported herewith information concerning the production of aluminum and fabrication of aluminum in Germany, supplied from the following two sources, both considered reliable.

a. Compagnie de Produits Chimiques et Electrométallurgiques, Alais, Froges et Camargue, Paris.

b. Dr. G. Chaudron, Faculté des Sciences, Universite de Paris, in collaboration with Dr. Hérenguel.

2. Raw materials. Most of the bauxite was imported into Germany from Hungary and Yugoslavia. The ordered stocks are in considerable quantity and are estimated to cover the needs for several years.

3. In general, all electric power is supplied by power houses with the exception of plants located on Inn, an affluent of the Danube, and on the Rhine, which are supplied by hydroelectric power.

4. Alumina Works. The total capacity is estimated at 700,000 tons a year, distributed over five principal factories as follows:

Lautawerk, situated in Saxony between Kottbus and Bautzen on the Leipzig to Breslau line, at 20 Kilometers from Ruhrand and 60 Kilometers from Horka	140,000 tons
Bergheim/Erftwerk, west of Cologne	150,000 tons
Mundenheim, near Ludwigshafen	200,000 tons
Lünen, in Westphalia, at 17 Kilometers northeast of Dortmund on Lippe	90,000 tons
Schwandorf, in Bavaria, at 42 Kilometers north of Ratisbonne	125,000 tons

SPCWH
(19 Oct 44)

Two other factories were reported but the French have no recent information on them.

A factory located on Höchst a/Mein, which belonged to I.G. Farben-Industrie, and made 5000 tons of alumina in prewar years.

A factory at Dölau which was owned by Zeschimer & Schwarz Company and was making at that time 2000 tons.

5. Aluminum Works. The total German capacity is estimated at 300,000 tons a year as follows:

Lautawerk (see above)	60,000 to 70,000 tons
Lünen (See above)	45,000 tons
Erftwerk (Grevenbroich-Rhenanie of the north, at 25 Kilometers southwest of Dusseldorf)	30,000 tons
Mattiwerk on Inn, in Bavaria	66,000 tons
Bitterfeld, near Hall	60,000 to 70,000 tons
Rheinfelden (Duchy of Baden on the Rhine, near the city of same name. Factory owned by a Swiss company of Nenhausen)	39,000 tons

Mattiwerk is the most recent. It was built in 1940, occupies an area of 150 hectares, and employs 3000 people. Its power installations must be of the order of 150,000 KW.

6. Further information on concerns which produce aluminum and half-and-half light alloys. The combined output of two companies, Dürener Metallwerke A.G. and Vereinigte Leicht Metallwerke G.m.b.H., amounted in 1943 to about 70% of the total German half-and-half light alloy production.

Information about these two concerns follows:

Dürener Metallwerke A.G., Berlin

Works: Düren (Station: Düren - North)
Waren (Mecklembourg)
Wittenau (Station: Berlin - Reinickendorf)

Figure D.535: M. B. Chittick. 19 October 1944. Subject: German Aluminum, production and fabrication; German Magnesium [NARA RG 77, Entry UD-22A, Box 165, Folder ALSOS MATERIAL].

H. Calcium

Figure D.537: Flowchart of German methods of using calcium to process uranium and thorium [BIOS 675].

Henry S. Lowenhaupt. 1996. Chasing Bitterfeld Calcium. CIA Historical Review Program. https://www.cia.gov/static/Chasing-Bitterfeld-Calcium.pdf

In December 1946 a chemical engineer from the former I. G. Farben plant at Bitterfeld in East Germany volunteered in Berlin that this plant "had started in the past few weeks producing 500 kilograms per day of metallic calcium. Boxes of the chemical are sent by truck every afternoon to Berlin, labeled to Zaporozhe on the Dnieper. Calcium is believed to be used as a slowing agent in processes connected with the production of atomic explosive."

This was the lead we in the Foreign Intelligence Section of the Manhattan District Headquarters had been waiting for. We had read the technical investigation reports from FIAT (Field Information Agency /Technical) on the production of uranium at the Auergesellschaft Plant in Berlin/Oranienburg. We also knew that Dr. Nikolaus Riehl—with his whole research team from Auergesellschaft—had met the Russians, volunteering to help them make uranium for their atomic bomb project. We knew from intercepted letters that the group was still together, writing from the cover address PO Box 1037P, Moscow. We knew Auergesellschaft during World War II had made the uranium metal for the German Uranverein—the unsuccessful German atomic bomb project—by using metallic calcium to reduce uranium oxide to uranium metal (not as "slowing agent"). We had analyzed the two-inch cubes of uranium metal from the incomplete German nuclear reactor which the Alsos Mission had found in the minuscule village of Stadtilm in Thuringia. We knew German uranium was terrible—full of oxides and voids, though it was fairly pure otherwise by non-atomic standards. The files also disgorged that in 1945 the Russians had started to dismantle and take to Russia the small calcium plant at the enormous Bitterfeld Combine, in addition to the big magnesium facility.

Cables went out immediately to the European Command in Germany via G-2 and directly to Col. Edgar P. Dean, Manhattan District representative in London, to locate and interrogate all engineers who had fled Bitterfeld to the West or were currently willing to sell information on their unloved masters. We wanted to know how much calcium was to be produced, what its specifications were, and where it was to be shipped. We wanted to know what non-atomic normal German industries used calcium, and in what quantities. We wished Col. Dean to keep our British colleagues in the Division of Atomic Energy, Ministry of Supply, informed.

At home, the Scientific Division of the Office of Special Operations in the newly-formed Central Intelligence Group was also apprised of our needs. Col. Frank A. Valente of our section was asked to take time out from his task of organizing an atomic detection system to talk to the U.S. Atomic Energy Commission in depth about the use in the U.S. program of calcium to reduce uranium salts to uranium metal. Major Randolph Archer, also of our office, was asked to talk to U.S, firms making calcium metal, and find out what it was used for and in what quantities.

As so often happens, the people involved and their experience were crucial ingredients. On the American side was the Foreign Intelligence Section of the Washington Liaison Office of the Manhattan District, then in the process of transferring as a unit to the newly formed Central Intelligence Group. It was headed by Col. L. E. Seeman, a career Corps of Engineers officer who had run the American engineering forces of the CBI theater during World War II and would go on to become major general. The section was staffed with a few career Corps of Engineers personnel, several officers and civilians trained in science, and the remainder trained in investigative procedures in the Counter Intelligence Corps.

The orientation toward engineering on the part of our management led directly to a pragmatic approach—do what works, and get on with the job. The engineering orientation also led materially toward the estimative method of technical evaluation. Engineering officers are accustomed to laying out engineering tasks to find out how long they will take at a minimum—and then to evaluate likely slippage. They think in quantitative terms—man days, truckloads, cubic yards. The scientific side of the section, Col. Valente, Mr. Charles Campbell, Mr. Donald Quigley, and I learned gradually to ferret out the crucial technical facts, the bottlenecks as it were, that could be used in these engineering-type evaluations.

A remnant of the wartime cooperation in the atomic field was the direct liaison at that time with the Intelligence Section of the British Division of Atomic Energy of the Ministry of Supply. Col. Dean, Assistant Military Attaché, was our representative in London. This cooperation was normalized gradually into more regular country-to-country liaison channels after our section was deployed to the newly formed CIG early in 1947. The Atomic Energy Act of 1946, which restricted much atomic data to "cleared" U.S. personnel, also tended to perpetuate differences between the U.S. and UK intelligence efforts already in being in 1946 because of the "nationalistic" policies on the parts of both General Leslie R. Groves, Manhattan District Commander, and Sir John Anderson, head of the UK atomic effort.

The British office was staffed with technical personnel, much as our own was. Mr. David Gattiker, their liaison to our section, had been a chemical engineer with Imperial Chemicals Incorporated before World War II. Mr. Kenneth Townley, one of the London members, was a geologist by profession with some experience in uranium prospecting. Its leader, Commander Eric Welsh, however, was also a career member of MI-6. Commander Welsh had masterminded the sabotage of Norsk Hydro in Norway in 1943 to prevent the Germans from getting heavy water and completing an operating reactor at Stadtilm. In 1940 he had been instrumental in smuggling the great nuclear physicist Niels Bohr out of occupied Denmark. And in the thirties he had been a chemist at Bitterfeld.

Returning to the calcium problem, by mid-January 1947 the Bitterfeld activity was definitely confirmed, and indeed amplified: Russian requirements were for 30 tons of metallic calcium per month, and distillation was needed to achieve adequate purity. A number of former Bitterfeld engineers were soon interviewed, especially by Major Paul O. Langguth working for Col. Dean in London. As we learned more, some were even re-interviewed. I remember, for instance, flying to Wright Patterson Airbase in late 1947 to talk once again to a Bitterfeld metallurgist whom Langguth had previously interrogated, and who had in the interim come to the U.S. as a member of the Air Force's Operation PAPERCLIP. [...]

[During the war, German industry produced calcium and used it to purify uranium and thorium (pp. 4134–4135). After the war, German industry continued to produce calcium for nuclear purposes—for the Soviet Union, as shown by the above document.]

I. Nickel

[Nickel was used for nickel-cadmium batteries and certain alloys. Yet because nickel is much more resistant than other metals to corrosion by uranium hexafluoride (used in uranium enrichment), it would have been invaluable in a nuclear program. The following documents demonstrate large-scale production of nickel.]

For information on wartime nickel production and applications, see for example:

J. Zirconium

[Zirconium was used for high-temperature metals and ceramics in non-nuclear applications, but its high temperature resistance and other properties also would have made it ideal as a fuel cladding material in fission reactors.]

FIAT 750. *Rare and Minor Metals.* p. 16. [See document photos on p. 4143.]

[...] The element is imported principally in the form of zircon mixed with monazite. In 1936 the production of metallic zirconium was 2,000 kg. and the pre-war price (1938) was RM 35 per kg. There are three producers of the metal:

Deutsche Gold- und Silver-Scheideanstalt[...]

I.G. Farbenindustrie A.G.[...]

I. D. Riedel—E. de Haen A.G.[...]

These documents also demonstrate commercial production and use of zirconium:

> BIOS 276. *Telefunken Gesellschaft für Drahtlose Telegraphie m.b.h., Berlin; Special Materials for Radio Valves.* [Zirconium for radio valves, treatment of.]
>
> BIOS 896. *The Manufacture of Zirconium-Potassium Fluoride, Zirconium Oxide and Zirconium Oxychloride.*

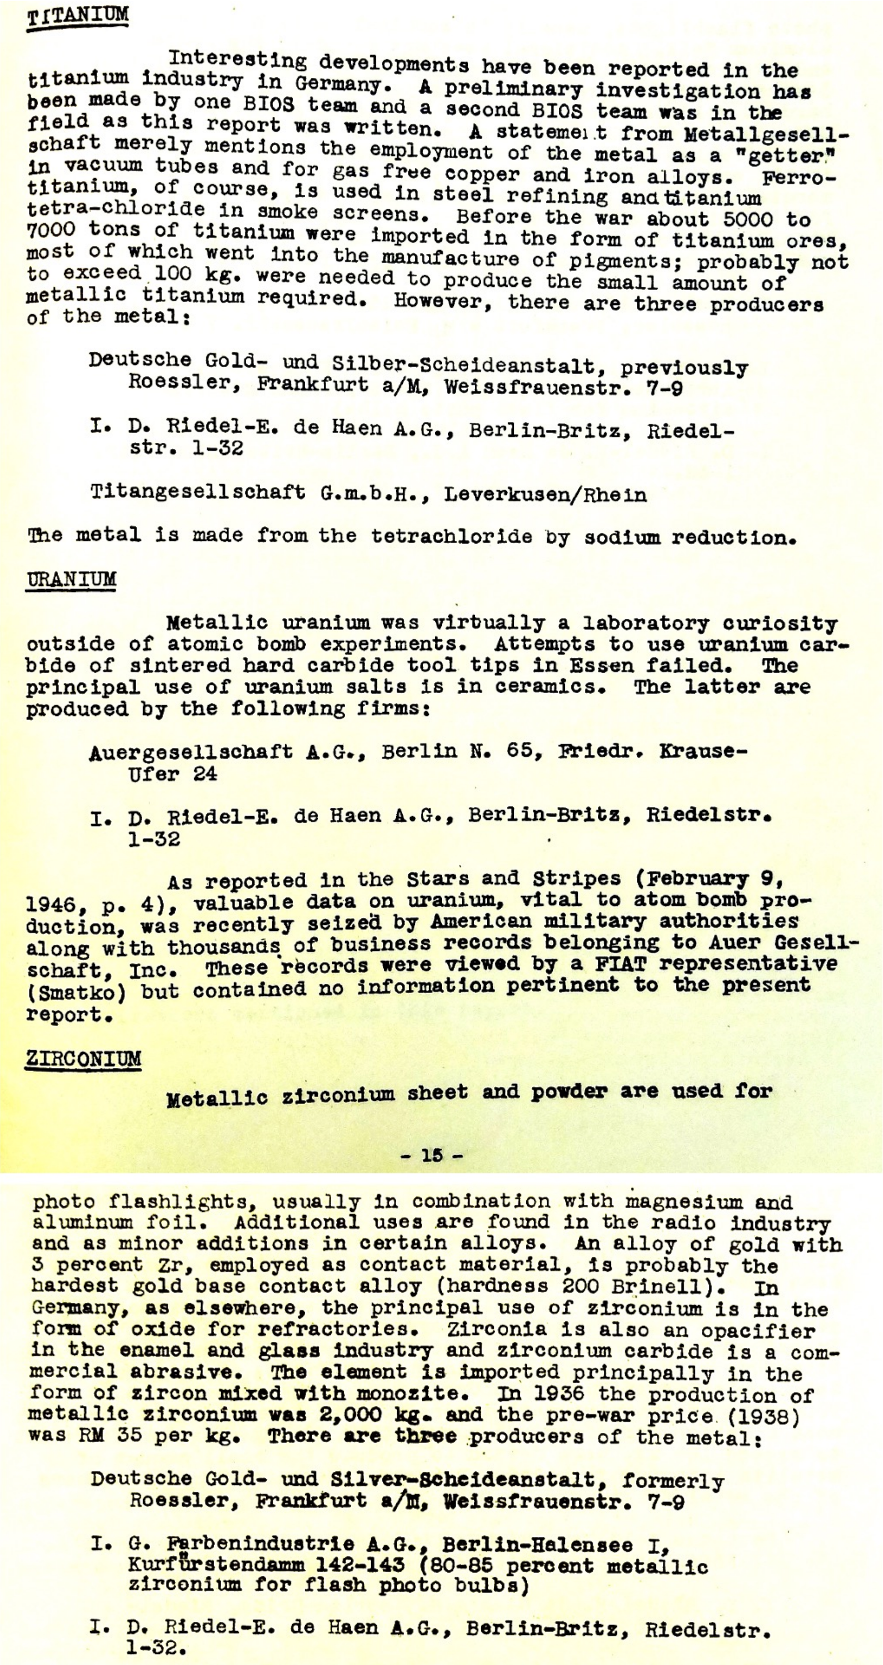
> FIAT 1048. *The Production of Zirconium Oxide.*

[For documentation of the shipment of zirconium to Japan, along with other apparently nuclear-related materials, see p. 4094. This evidence suggests that at least some of the zirconium produced in Germany during the war was intended for nuclear applications.]

FIAT 750. *Rare and Minor Metals*



TITANIUM

Interesting developments have been reported in the titanium industry in Germany. A preliminary investigation has been made by one BIOS team and a second BIOS team was in the field as this report was written. A statement from Metallgesellschaft merely mentions the employment of the metal as a "getter" in vacuum tubes and for gas free copper and iron alloys. Ferro-titanium, of course, is used in steel refining and titanium tetra-chloride in smoke screens. Before the war about 5000 to 7000 tons of titanium were imported in the form of titanium ores, most of which went into the manufacture of pigments; probably not to exceed 100 kg. were needed to produce the small amount of metallic titanium required. However, there are three producers of the metal:

Deutsche Gold- und Silber-Scheideanstalt, previously Roessler, Frankfurt a/M, Weissfrauenstr. 7-9

I. D. Riedel-E. de Haen A.G., Berlin-Britz, Riedelstr. 1-32

Titangesellschaft G.m.b.H., Leverkusen/Rhein

The metal is made from the tetrachloride by sodium reduction.

URANIUM

Metallic uranium was virtually a laboratory curiosity outside of atomic bomb experiments. Attempts to use uranium carbide of sintered hard carbide tool tips in Essen failed. The principal use of uranium salts is in ceramics. The latter are produced by the following firms:

Auergesellschaft A.G., Berlin N. 65, Friedr. Krause-Ufer 24

I. D. Riedel-E. de Haen A.G., Berlin-Britz, Riedelstr. 1-32

As reported in the Stars and Stripes (February 9, 1946, p. 4), valuable data on uranium, vital to atom bomb production, was recently seized by American military authorities along with thousands of business records belonging to Auer Gesellschaft, Inc. These records were viewed by a FIAT representative (Smatko) but contained no information pertinent to the present report.

ZIRCONIUM

Metallic zirconium sheet and powder are used for photo flashlights, usually in combination with magnesium and aluminum foil. Additional uses are found in the radio industry and as minor additions in certain alloys. An alloy of gold with 3 percent Zr, employed as contact material, is probably the hardest gold base contact alloy (hardness 200 Brinell). In Germany, as elsewhere, the principal use of zirconium is in the form of oxide for refractories. Zirconia is also an opacifier in the enamel and glass industry and zirconium carbide is a commercial abrasive. The element is imported principally in the form of zircon mixed with monozite. In 1936 the production of metallic zirconium was 2,000 kg. and the pre-war price (1938) was RM 35 per kg. There are three producers of the metal:

Deutsche Gold- und Silver-Scheideanstalt, formerly Roessler, Frankfurt a/M, Weissfrauenstr. 7-9

I. G. Farbenindustrie A.G., Berlin-Halensee I, Kurfürstendamm 142-143 (80-85 percent metallic zirconium for flash photo bulbs)

I. D. Riedel-E. de Haen A.G., Berlin-Britz, Riedelstr. 1-32.

Frederic A. C. Wardenburg and Samuel A. Goudsmit. 18 November 1944 [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-1 GERMANY: Personnel (Mar 43–Dec 44)].

In our investigations of the Soc. de. Terres Rares (STR) in Paris we uncovered the following information, as reported in part before: [...]

Dr. Jansen worked with Ford in Cologne until the end of 1942. He was then hired by Auer and sent to Paris in January 1943. He returned to Germany only for occasional visits. [...]

After reporting to Dr. Ihwe, he was sent back to Saarbrucken to start a search for a lost railroad car loaded with zirconium and other products of the STR. [...]

According to Jansen, Dr. Ihwe is about 50 years old. He studied at Darmstadt and has been with Auer probably five or six years. He is very ambitious, a "Streber." Dr. Ihwe is in complete charge of the department of Rare Earths of the Auer Company. This department has all its facilities at Oranienburg. He is in charge of research as well as applications and some commercial matters. [...]

Jansen had only a very superficial knowledge of the materials produced by STR. He asked Ihwe what it was used for, but received the answer that it was secret. [...]

Jansen said that the Germans removed the electro-magnetic separator and classifier from the STR plant at Serquigny.

[See photos of the first two pages of this document on p. 4145.

The same Auer Oranienburg plant that spent the war acquiring and processing uranium for secret programs was also acquiring railroad cars worth of zirconium for secret programs, and its officials were eager to make sure that no zirconium went to waste. This evidence suggests that some if not all of the zirconium was intended for nuclear applications.]

ALSOS Mission

18 November 1944

SUBJECT: Dr. Jansen, Auer representative in Paris.
Information about Dr. Ihwe of Auer.
Information about Hechingen, Württ.

* * * * * * * * * *

In our investigations of the Soc. d. Terres Rares (STR) in Paris we uncovered the following information, as reported in part before:

Dr. Ihwe of Auer was officially put in charge of the STR. He is the chemist who was connected with the removal of stocks from Belgium for Auer. Dr. Ihwe travelled much and visited Paris only at regular intervals.

Dr. Jansen, an insignificant law graduate, was the representative of Ihwe at the Paris office of the STR.

Jansen's confidential secretary was a Miss Ilse Hermanns.

Very few papers were left behind at the office of the STR. Among those was a listing of registered mail sent by Dr. Jansen. Almost all of this mail was addressed to Auer. However, the last letter was addressed to Miss Ilse Hermanns at Eupen.

As we are especially interested in the movements of Dr. Ihwe, while in occupied territory, we considered it advisable to attempt to locate Miss Hermanns, on the chance that she might still be at Eupen, which is now in American hands.

As inquiries through channels failed, Lt. Colonel Pash and Pfc Leonard went to Eupen and succeeded in finding Miss Hermanns. Thanks to Colonel Pash's alertness he discovered that Dr. Jansen himself was there too. Informing us by telephone of his discovery it was decided that he bring Dr. Jansen to Paris for questioning. Colonel Pash also discovered several papers belonging to Dr. Jansen and Miss Hermanns.

Among the papers were documents and letters indicating that both Dr. Jansen and Miss Hermanns had visited Dr. Ihwe at Oranienburg early in September.

It was also revealed that Dr. Jansen's mother lived in Hechingen Württ. and that Jansen visited her for three days before going to Berlin.

Subject: Dr. Ihwe, Jansen, Hechingen. (cont'd) 18 Nov 1944

Dr. Jansen worked with Ford in Cologne until the end of 1942. He then was hired by Auer and sent to Paris in January 1943. He returned to Germany only for occasional visits. In the spring of 1943 he visited his mother at Hechingen. He left paris, after some difficulties with the German authorities, in August 1944 and returned to Berlin stopping over at Hechingen again.

After reporting to Dr. Ihwe, he was sent back to Saarbrucken to start a search for a lost railroad car loaded with Zirconium and other products of the STR. He used this occasion to visit Miss Hermanns at Eupen, where the front overtook him and he was cut off.

Interrogation of Dr. Jansen about Dr. Ihwe and Auer:

According to Jansen, Dr. Ihwe is about 50 years old. He studied at Darmstadt and has been with Auer probably five or six years. He is very ambitious, a "Streber". Dr. Ihwe is in complete charge of the department of Rare Earths of the Auer Company. This department has all its facilities at Oranienburg. He is in charge of research as well as applications and some commercial matters. Ihwe complained that lately administrative duties distracted him too much from his technical work. He told Jansen, who doesn't know any chemistry at all, that Rare Earths chemistry is a very difficult highly specialized subject, that very few chemists know anything about it, that Ihwe never was trained for it and had to acquire all this knowledge after joining Auer.

Jansen had only a very superficial knowledge of the materials were produced by STR. He asked Ihwe what it was used for, but received the answer that it was secret. Jansen heard that it was used for search light carbons and colored lenses. The zirtonium oxychloride was used for waterproofing uniforms. Mesothorium was used for luminous dials. According to Gregory it was probably exported again to Switzerland in exchange for watches or similar instruments or for foreign exchange. The STR produced a few grams for them during the occupations. We also found documents indicating some shady black market deals in Mesothorium.

Jansen said that the Germans removed the electro-magnetic separator and classifier from the STR plant at Serquigny. ~~Answered that it was a secret and that he couldn't tell Jansen what it was for.~~ ~~Jansen gathered from hear say that it was used for search light carbons and for colored lenses. The Zirconium oxychloride is used for waterproofing uniforms.~~

Dr. Ihwe visited Paris about every six weeks. He traveled much, also to Southern France, looking for material. Jansen knew no details about his movements. He believed that Ihwe was looking for monazite, which had not reached its destination, STR, when France was occupied. Jansen told about a shipment of monazite which was destined for France but which was diverted by the French so as not to fall into German

NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-1 GERMANY: Personnel (Mar 43-Dec 44)

Figure D.541: Frederic A. C. Wardenburg and Samuel A. Goudsmit. 18 November 1944 [NARA RG 77, Entry UD-22A, Box 167, Folder 32.12-1 GERMANY: Personnel (Mar 43–Dec 44)]. "After reporting to Dr. Ihwe, he was sent back to Saarbrucken to start a search for a lost railroad car loaded with zirconium and other products of the STR."

[Further evidence of German zirconium production for nuclear purposes comes from a postwar shipwreck, as shown on p. 4147.

The SS *Flying Enterprise*, a commercial U.S. cargo ship, left Hamburg on 21 December 1951 with a variety of cargo headed for the United States. While passing near the southern coast of England, the ship was badly damaged in a storm on 25 December 1951. Despite extensive efforts by other ships to prevent the *Flying Enterprise* from sinking, it finally went down on 10 January 1952. (Everyone onboard was saved except for one person.)

In later interviews, the captain of the *Flying Enterprise*, Kurt Carlsen, stated that among the cargo was five tons of German-produced zirconium, left over from the wartime German nuclear program and destined to be used as cladding for the uranium fuel rods in the first U.S. nuclear submarine, USS *Nautilus*. Carlsen also stated that Navy divers salvaged the zirconium from the underwater wreck of his ship and took the zirconium back to the United States, causing a six-month delay in the launch of the Nautilus (finally launched in 1954).

This information confirms that some of the German zirconium that was being produced during the war was specifically intended for nuclear applications. It is not clear if those applications included submarine reactors, breeder reactors for producing plutonium, or other purposes. It is also not clear how far such nuclear work progressed in Germany during the war.

Any U.S. government documents on this shipment of zirconium or its origins in the wartime German nuclear program appear to remain classified and unavailable. This incident seems to confirm that the U.S. government has a much deeper knowledge of the wartime German nuclear program than it has admitted publicly, and that that knowledge shows the German nuclear program to have been more advanced than has been publicly stated.]

Bjarne Bekker. 2013. *Flying Enterprise & Kurt Carlsen.* Svendborg, Denmark: Bekker. p. 141. http://flying-enterprise.øavisen.dk

The reactor on "Nautilus" needed zirconium from "Flying Enterprise"

Kurt Carlsen spoke of it as if it were a story about onshore shooting in the Faroe Islands, water skiing on the lakes at Silkeborg or landing a sports plane on the beach on the west coast on a visit to his in-laws in Tane near Blavand. Quietly and matter-of-factly he sat in his retirement in Woodbridge and explained the cargo of zirconium. That the American military and secret service had found the material in West Germany. That Hitler was to use it in his nuclear program and that it was now to be used in the reactor of the first nuclear submarine "Nautilus".

"The launch was delayed six months, because divers had to enter the "Flying Enterprise" and retrieve the five tons of zirconium. Several idiotic reporters at the time wrote that my cargo was nuclear bombs. That was so wrong. My cargo was a material which encapsulates radioactivity".

571
NAUTILUS

Figure D.542: The SS *Flying Enterprise* sank on 10 January 1952 while carrying cargo from Hamburg to the United States. Its captain, Kurt Carlsen, later told interviewers such as Bjarne Bekker that the cargo included five tons of zirconium, left over from the wartime German nuclear program, which was salvaged from his sunken ship and used in the first U.S. nuclear submarine, USS *Nautilus*.

K. Cadmium

[Cadmium was used for nickel-cadmium batteries and soldering, but it also could have been extremely useful as a neutron absorber.

The following documents illustrate the production and applications of cadmium, as well as methods for electroplating thin layers of materials such as cadmium onto aluminum (which could be useful for nuclear applications).

German capabilities to electroplate cadmium on aluminum are potentially quite relevant for creating a neutron-absorbing cadmium layer on a spherical aluminum pusher as in the German fission implosion bomb described in March 1945—see p. 4486.

For a description of how cadmium was mined on a large scale with specific knowledge of its utility in atomic bombs, see p. 4255.]

[p. 27:] 3 CADMIUM—Supply and Consumption

SOURCES OF INFORMATION

The information on supply was obtained from the same sources as that on the supply of zinc, viz; the Reichsstelle Eisen und Metalle and the Metallgesellschaft. The production figures obtained from the former were said to be actual figures and not estimates; but it is thought that the export and import figures from the latter are estimates only.

TOTAL SUPPLY

The following table, in metric tons, shows German and Austrian production and includes that from Upper Silesia from September, 1939, from the following Smelters—Giesche (Kattowitz), Hohenlohe and Schlesag:

	1938	1939	1940	1941	1942	1943	1944
PRODUCTION	437	477	531	608	484	496	404
Imports	100	253	86	1	72	10	7
TOTAL SUPPLY	537	730	617	609	556	506	411
less exports	50	47	62	37	128	108	29
NET SUPPLY	487	683	555	572	428	398	382

[p. 28:] CONSUMPTION

No figures on consumption for various purposes could be obtained, but the team was informed that the main uses before the war were alkaline accumulators for mining lamps, cadmium pigments, cadmium plating instead of nickel for bearing alloys.

During the war the main uses were in accumulators [nickel-cadmium batteries] for the Forces—submarines, etc. and in cadmium alloy solders used as a substitute for tin-lead solders. [...] Other uses were severely curtailed, cadmium pigments being used only for military requirements.

[See document photos on p. 4151.]

Total:	80,000	95,000	110,000	120,000	100,000	84,000	75,000

3 CADMIUM - Supply and Consumption

SOURCES OF INFORMATION

The information on supply was obtained from the same sources as that on the supply of zinc, viz; the Reichsstelle Eisen und Metalle and the Metallgesellschaft. The production figures obtained from the former were said to be actual figures and not estimates; but it is thought that the export and import figures from the latter are estimates only.

TOTAL SUPPLY

The following table, in metric tons, shows German and Austrian production and includes that from Upper Silesia from September, 1939, from the following Smelters - Giesche (Kattowitz), Hohenlohe and Schlesag:

	1938	1939	1940	1941	1942	1943	1944
PRODUCTION	437	477	531	608	484	496	404
Imports	100	253	86	1	72	10	7
TOTAL SUPPLY	537	730	617	609	556	506	411
less exports	50	47	62	37	128	108	29
NET SUPPLY	487	683	555	572	428	398	382

INDIVIDUAL SMELTER PRODUCTION

It will be observed from the above table that production rose rapidly in 1940 & 1941, but then fell again to the 1938-39 level. The following table shows that the rise was due to the incorporation of the Upper Silesian Smelters in the Reich. The fall from 1942 onwards was due to the decline in the production of Giesche (Magdeburg) together with the decline and eventual extinction of Marquart for reasons unknown to the team. The Giesche (Magdeburg) smelter is believed to have been severely damaged in air raids.

3

27

	1938	1939	1940	1941	1942	1943	1944
Berzelius	44	48	37	54	44	64	62
Giesche (Mag.)	261	240	250	240	178	200	140
Marquart	132	113	9	88	22	-	-
Unterharzer	-	-	-	-	8	12	7
	437	401	296	382	252	276	209
Giesche (Katt.)		58	149	141	159	153	129
Hohenlohe		11	60	62	43	47	40
Schlesag		7	26	23	30	20	26
	437	477	531	608	484	496	404

In the case of the last 3 smelters, the figures for 1939 represent production subsequent to their incorporation in the Reich. The following table shows their production in January - August, 1939, before their incorporation:-

Giesche (Katt.)	102
Hohenlohe	15
Schlesag	28
	145

CONSUMPTION

No figures on consumption for various purposes could be obtained, but the team was informed that the main uses before the war were alkaline accumulators for mining lamps, cadmium pigments, cadmium plating instead of nickel for bearing alloys.

During the war the main uses were in accumulators for the Forces - submarines, etc. and in cadmium alloy solders used as a substitute for tin-lead solders. At first a solder containing 85% cadmium was used, but this was replaced later by one containing only some 17% cadmium. Other uses were severely curtailed, cadmium pigments being used only for military requirements.

BIOS 1615. ***The German Metal Finishing Industry.***

[p. 5:] Cadmium Plating

This is employed to a limited extent and the solutions are analogous to the higher current density type used in this country. [...]

[p. 8:] Plating on Aluminium and its Alloys

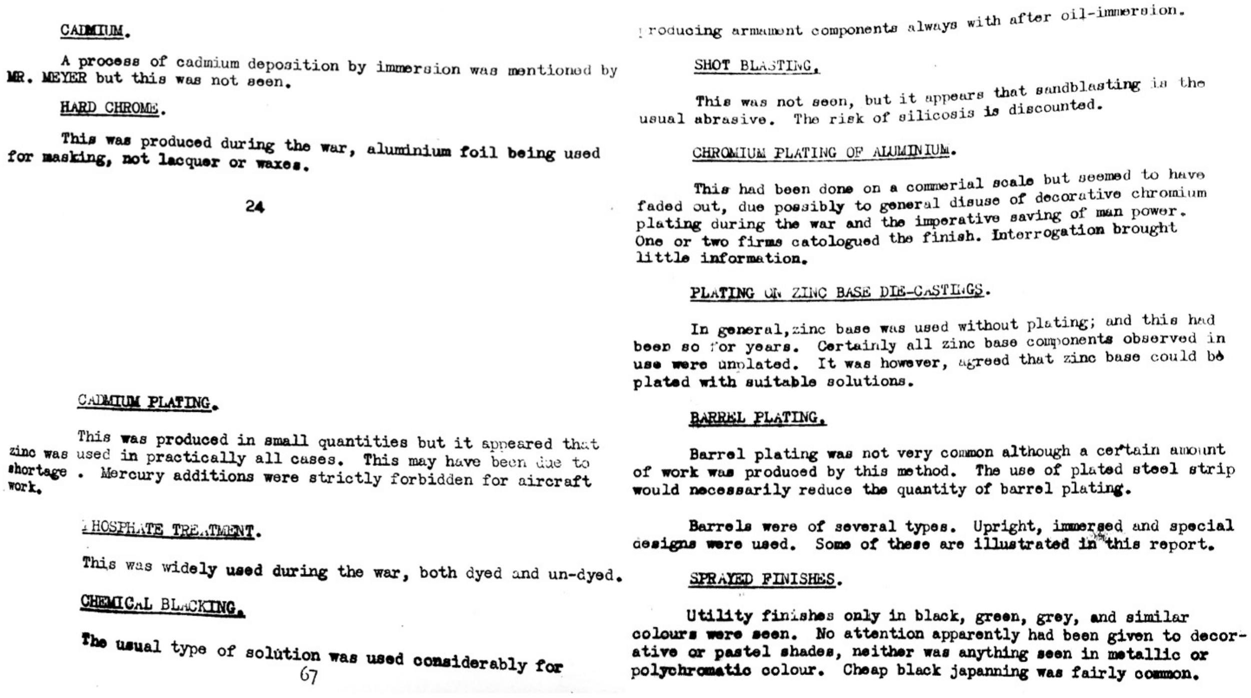
Although aluminium is widely used in Germany, no actual samples of nickel plus chromium plated aluminium were seen. Samples of lead plated battery lugs were encountered at Robert Bosch, Stuttgart and direct chromium plated aluminium at Blasberg's, Sollingen. Numerous references are made to the plating of aluminium and its alloys, however, and the most popular treatment for plating on this metal appears to be a primary application of a zincate dip followed by either a copper or brass deposit and then final plating.

[See document photos on p. 4153.]

For more technology for electroplating on aluminum, see:

BIOS 429. *German Electroplating Industry.*

BIOS 1009. *A Survey of German Electro-Plating Methods*



CADMIUM.

A process of cadmium deposition by immersion was mentioned by MR. MEYER but this was not seen.

HARD CHROME.

This was produced during the war, aluminium foil being used for masking, not lacquer or waxes.

24

CADMIUM PLATING.

This was produced in small quantities but it appeared that zinc was used in practically all cases. This may have been due to shortage . Mercury additions were strictly forbidden for aircraft work.

PHOSPHATE TREATMENT.

This was widely used during the war, both dyed and un-dyed.

CHEMICAL BLACKING.

The usual type of solution was used considerably for producing armament components always with after oil-immersion.

67

SHOT BLASTING.

This was not seen, but it appears that sandblasting is the usual abrasive. The risk of silicosis is discounted.

CHROMIUM PLATING OF ALUMINIUM.

This had been done on a commerial scale but seemed to have faded out, due possibly to general disuse of decorative chromium plating during the war and the imperative saving of man power. One or two firms catologued the finish. Interrogation brought little information.

PLATING ON ZINC BASE DIE-CASTINGS.

In general, zinc base was used without plating; and this had been so for years. Certainly all zinc base components observed in use were unplated. It was however, agreed that zinc base could be plated with suitable solutions.

BARREL PLATING.

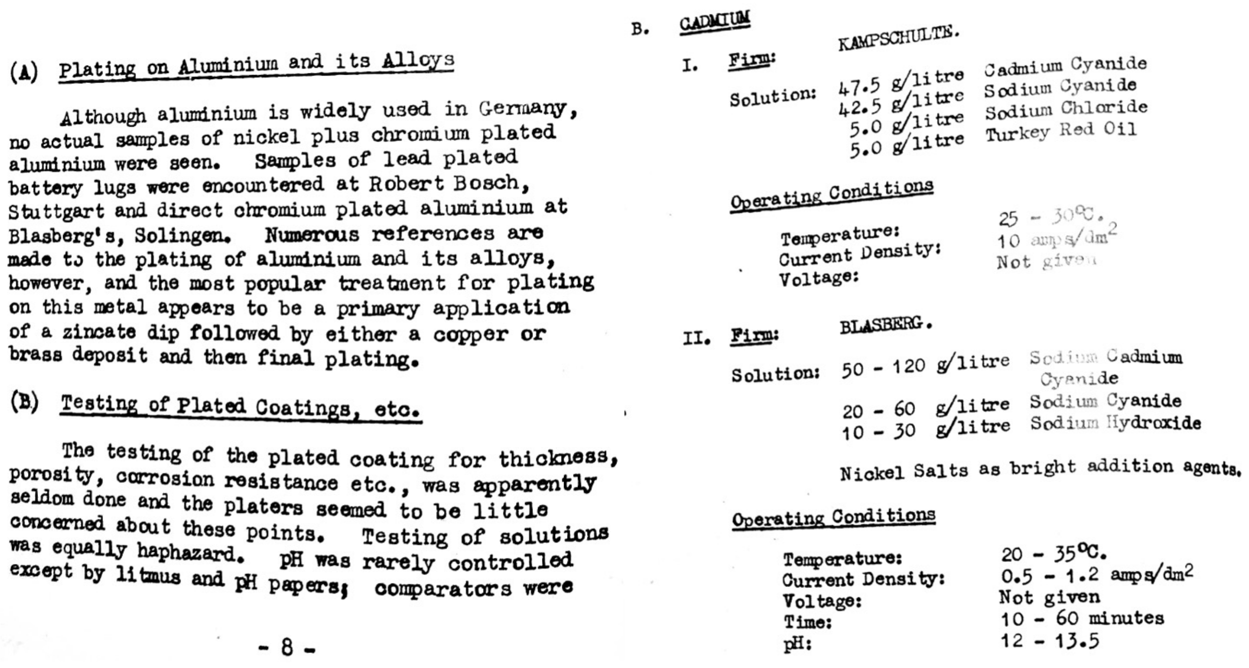
Barrel plating was not very common although a certain amount of work was produced by this method. The use of plated steel strip would necessarily reduce the quantity of barrel plating.

Barrels were of several types. Upright, immersed and special designs were used. Some of these are illustrated in this report.

SPRAYED FINISHES.

Utility finishes only in black, green, grey, and similar colours were seen. No attention apparently had been given to decorative or pastel shades, neither was anything seen in metallic or polychromatic colour. Cheap black japanning was fairly common.

BIOS 1615. *The German Metal Finishing Industry*



(A) Plating on Aluminium and its Alloys

Although aluminium is widely used in Germany, no actual samples of nickel plus chromium plated aluminium were seen. Samples of lead plated battery lugs were encountered at Robert Bosch, Stuttgart and direct chromium plated aluminium at Blasberg's, Solingen. Numerous references are made to the plating of aluminium and its alloys, however, and the most popular treatment for plating on this metal appears to be a primary application of a zincate dip followed by either a copper or brass deposit and then final plating.

(B) Testing of Plated Coatings, etc.

The testing of the plated coating for thickness, porosity, corrosion resistance etc., was apparently seldom done and the platers seemed to be little concerned about these points. Testing of solutions was equally haphazard. pH was rarely controlled except by litmus and pH papers; comparators were

D.8 Fission Bomb Design

[The following documents demonstrate that the German nuclear program had sophisticated implosion bomb designs that would be highly suitable for either a fission implosion bomb or a fusion-boosted fission implosion bomb, and moreover that the German program carried out serious experimental work on implosion bombs from an early date. The most important design details are summarized in Table D.2.

Adolf Busemann (German, 1901–1986), Rolf Engel (German, 1912–1993), Gottfried Guderley (German, 1910–1997), Walter Hantzsche (German, 19??–19??), Rudi Schall (German, 1913–2002), Hubert Schardin (German, 1902–1965), Erich Schumann (German, 1898–1985), Walter Trinks (German, 1910–1995), Hilmar Wendt (German, 1913–19??), and many others worked in teams that developed and demonstrated implosion bomb designs:

- H. Rausch von Traubenberg and other scientists in the German-speaking world began using neutron reflectors around their nuclear reaction experiments no later than 1936 (pp. 4158–4159).

- Herbert Wagner and other scientists at the Henschel aircraft company proposed nuclear weapons at the beginning of the war and apparently worked to develop them during the war (pp. 4160–4166).

- No later than 1940, the German mathematicians Walter Hantzsche and Hilmar Wendt predicted the pressure, density, and temperature in spherical and cylindrical implosion bomb configurations, mathematical solutions that are still used today (pp. 4166–4169).

- No later than 1942, Gottfried Guderley, a hydrodynamics expert working for the German military, performed very similar calculations for spherical and cylindrical implosions (pp. 4170–4171).

- 1943 U.S. intelligence reports stated that "several factories and hundreds of workers" just south of Hamburg were producing an unusual material that was a new type of explosive, that was so energetic that one kilogram of the new material would have a blast radius of several kilometers, and that would be placed into bombs of a highly unusual spherical design (pp. 4172–4182, 4406).

- Manfred von Ardenne worked throughout the war to produce fission bombs each containing a few kilograms of uranium-235 (pp. 3561–3617, 4180, 4183–4184). After the war he played a key role in the Soviet nuclear weapons program.

- Based on several inside sources, on 22 October 1944 the *New York Times* reported that Germany was developing an atomic bomb that simultaneously used high-voltage electricity (i.e., a high-voltage fusion neutron initiator) and the detonation of surrounding conventional explosives (i.e., implosion) to release large amounts of energy from fission fuel ("the force of the disintegrating atoms"). See p. 4185.

- In November 1944, *Time* magazine published an intelligence report that Germany was developing an atomic bomb with a spherical implosion design to cause uranium fuel to fission in an explosive reaction (p. 4185).

- A 23 March 1945 letter from General Ivan Ilyichev to Joseph Stalin reported that Germany had built and successfully tested an atomic bomb, and described it in considerable detail as a 2-ton, 1.3-meter-diameter spherical implosion bomb with multiple concentric layers and a uranium-235 core (p. 4485).

- Erich Schumann, the German Army Ordnance Office's head physicist, along with others on his staff, worked throughout the war designing and testing ever more sophisticated bombs that used an outer shell of conventional explosives to implode an inner core of various materials, including nuclear fuels (pp. 4187–4255). (Schumann was also Wernher von Braun's Ph.D. thesis advisor for the development of rockets, as well as a key figure in Germany's biological warfare program and several other advanced research programs. Yet Goudsmit testified to the U.S. Senate that Schumann was mainly interested in "the physics of piano strings.")

- In November 1945, the German economist Erwin Respondek wrote that Erich Schumann had been involved in the development of an atomic bomb that used uranium fuel and a neutron initiator (and apparently Schumann's expertise, conventional explosives for spherical implosion) (p. 4194).

- The implosion expert Walter Trinks worked closely with Schumann during the war. Trinks was imprisoned by the U.S. Army from June 1945 to June 1946, and he informed them that "At the end of the war I was occupied with experiments for... the initiation of atomic bombs" (pp. 4257–4259).

- A Top Secret U.S. cable from March 1946 stated that a "capable young engineer" in Poland knew that atomic bomb casings included a layer of cadmium, which was true for the implosion bomb designs described by both Ilyichev and Schumann (p. 4255).

- A 1946 U.S intelligence report (which was not declassified until 2006) stated that at the end of the war, General Hans Kammler's deputy Erich "Purucker was driving a large civilian car which contained many of the plans on the atom bomb. This car plus material fell into the hands of the Russians" (p. 4914).

- A U.S. intelligence card catalog shows that there were postwar reports giving details of the German atomic bomb plans, but those reports are still classified and unavailable to the public (pp. 5074–5074).

- After the war, Kurt Diebner discussed spherical implosion bomb designs, specifically showing a spherical core of fission fuel with a center of fusion fuel (pp. 4260–4267).

- German witnesses described secretive and mysterious work that had been conducted during the war to produce and test nesting aluminum spheres that apparently matched the description of those in the implosion bomb designs (p. 4270).

- Hubert Schardin led a Luftwaffe research group that also appears to have been developing fission implosion bombs during the war, and he aided the French nuclear weapons program after the war (pp. 4190, 4268–4269). [See also Krehl 2009, pp. 1160–1162; Nagel 2012, p. 149 ff.]

- In 2000–2002 interviews, Heinrich Himmler's chief adjutant, Werner Grothmann, mentioned the development of an atomic bomb that "would have possessed a spherical shape with a diameter of over one meter. It was very heavy, even though the bomb body itself was supposed to be out of aluminum. It was said, if one reduces the weight, the yield is not as high" (pp. 4271–4273).

- Werner Grothmann (pp. 4271–4273) and Erich Schumann and Walter Trinks (pp. 4187–4255) stated that there were actually several different versions of the implosion bomb design for different geometries (spherical vs. cylindrical), sizes, and fuels.

- German scientists also appear to have been aware of the gun-type fission bomb design [Karlsch and Walker 2005; Thirring 1946]. However, any development seems to have been focused on the implosion design, since it requires much less fission fuel and has a much higher efficiency than the gun design.

For sources describing weapon designs with a significant amount of fusion fuel as well as fission fuel, see Section D.9.]

Table D.2: Details about fission implosion bomb design from primary sources.

H. Rausch von Traubenberg and H. Adam. 1937. Über die Rückstreuung von Neutronen und die Herstellung von Räumen mit erhöhter Neutronenkonzentration. *Zeitschrift für Physik* 104:442–447.

Wir beabsichtigen, unsere Versuche mit schwerem Wasser als bremsender Substanz fortzusetzen, da bei diesem eine geringere Absorption von Neutronen (Tritonenbildung) zu erwarten ist.

Zum Schluß haben wir noch Versuche über die Richtungsverteilung der an Eisen gestreuten Neutronen angestellt. Zu diesem Zwecke wurde ein Eisenstab von 3x3 cm als "Reflektor" benutzt und die Aktivierung des Rhodiumzylinders in verschiedenen Orientierungen zum Eisenstab ermittelt. Jedoch konnte die Frage bei der Schwäche unserer Neutronenquelle trotz langer Meßreihen noch nicht eindeutig beantwortet werden und wir beabsichtigen daher, das Problem der Richtungsverteilung mit stärkeren Neutronenquellen erneut in Angriff zu nehmen.

Zusammenfassung. In der vorliegenden Untersuchung wurden die Resultate von Mitchell und Mitarbeitern über die starke Rückstreuung langsamer Neutronen an Eisen und Blei bestätigt. Es gelang in geschlossenen Hohlräumen (bis zu 9 Liter) durch Verwendung von reflektierenden Eisen- bzw. Bleiwänden Neutronenkonzentrationen herzustellen, die die Werte ohne reflektierende Wände um ein Vielfaches übertrafen. Auf diese Weise wurde erstmalig eine gewisse Anreicherung von Neutronen (Kernbestandteilen) in leeren Räumen erreicht und so die Möglichkeit gegeben, mit einem reinen "Neutronengas" ohne Anwesenheit von störender Materie zu arbeiten.

We intend to continue our experiments with heavy water as a moderating substance, since a lower absorption of neutrons (triton formation) is to be expected with this.

Finally, we performed experiments on the directional distribution of neutrons scattered by iron. For this purpose an iron rod of 3x3 cm was used as a "reflector" and the activation of the rhodium cylinder in different orientations to the iron rod was determined. However, given the weakness of our neutron source, the question could not yet be answered unambiguously, despite long series of measurements, and we therefore intend to tackle the problem of directional distribution again with stronger neutron sources.

Summary. In the present investigation, the results of Mitchell and coworkers on the strong backscattering of slow neutrons by iron and lead were confirmed. It was possible to produce neutron concentrations in closed cavities (up to 9 liters) by the use of reflecting iron or lead walls which exceeded many times the values without reflecting walls. In this way, for the first time, a certain enrichment of neutrons (nuclear constituents) was achieved in empty spaces, thus making it possible to work with a pure "neutron gas" without the presence of interfering matter.

[German scientists began using neutron reflectors around their nuclear reaction experiments no later than 1936. See Fig. D.545. Neutron reflectors are important for both fission reactors and fission bombs.

H. Rausch von Traubenberg also did important very early work on tritium production and fusion reactions. See p. 4281.]

Subject: Transmittal of Document.

To : Lt. Col. John Lansdale, Jr. and Major F. J. Smith,
Room 5119, New War Dept. Bldg., Washington, D. C.

1. Inclosed is a very interesting report written by Dr. Goudsmit. He has carefully reviewed three volumes in German recently found by Dr. Kuiper. Major Calvert is presently going through the documents again with a German speaker and is planning to forward them to you with additional observations.

2. Importance of these documents appear to me to be: (a) It is documentary evidence of the situation in Paris during the war such as we have never been able to obtain before. (b) It increases our interest in Bagge. (c) Henshel, Aircraft Corps., may have other documents or projects, although it is unlikely. (d) Other Concerns like Henshel may have taken a similar interest in TA work. (e) Watzlawek and Wagner may be worth interviewing.

SUBJECT: Henschel Interest in TA

A very interesting document has just been found by Dr. G. P. Kuiper of Alsos. It was fished out of a well near Göttingen. It is a three hundred page report written by Dipl. Ing. Watzlawek under the direction of Prof. Dr. Ing. H. Wagner of the Henschel Airplane Works. It is dated 5 August 1941, Berlin, Marchstrasse 10.

The purpose of the report is to alert the German authorities to the fact that nuclear physics can have war and economic applications of greatest importance. They point out that Germany is far behind and propose a large-scale plan for nuclear physics to be taken up jointly by industry, especially Henschel, and the German Air Ministry.

The first part gives a survey of modern applied nuclear physics and discusses the various future possibilities. Most of the information about American and other foreign developments is obtained from newspaper clippings. The two most revealing sources seem to be the New York Times of Sunday, May 5, 1940, and an article in the British periodical, Discovery, of September 1939. From these articles, they deduce (p. 18) that work is being done in the USA to produce a uranium bomb for use in the present war. On page 19, they discuss in detail the possible technical applications. On page 38, they mention that Dunning of Columbia University had a conference with President Roosevelt, after which the isotope separation research in the USA was declared secret; also, that large sums for nuclear research are provided by state and private industry such as Westinghouse and General Electric. However, in looking up the references for this statement, we find that they merely relate to rather large grants given for the building of cyclotrons and medical research as publis~~hed in~~ the American technical journals. On page 29, they stress the necessity for pursuing this type of work in Germany and give a quotation from Fermi. They then propose a three-year plan which would cost about 13,000,000 Marks. On page 33, they set aside 35,000 Marks for three persons to be used in the intelligence service, and it is stated that knowledge of results and methods in the USA would save a lot of time and expense in their own work, especially, as stated on page 252, because the Americans are withholding publication on their present work. On page 37, they claim that the execution of their plan might make it possible to eliminate the American lead. The main point of the plan is to have the whole effort centralized with industrial and state support.

The next part contains photographic copies and German, English and American articles on this subject.

2. Henschel Interest in TA 26 May 1945

One gets the general impression that this was a well thought out plan but probably did not get the support of the proper authorities. More information may probably be obtained about this from Wagner himself who was evacuated to the USA about May 20th by those interested in V-1 development. At the present time, we have no information about the whereabouts of Watzlawek.
